BRODIE'S DISSECTIONS.

"Dissections Illustrated," described as "A Graphic Handbook for Students of Human Anatomy," by Mr.

G. Gordon Brodie, of the Middlesex Hospital Medical School, (London: Whitaker & Co.), is a work in four parts, which is intended to take the place of Ellis's well-known plates, which, though of indisputable excellence, are too large to be portable, and too expensive for individual students. In order to obviate these drawbacks, the plates (drawn and lithographed by Percy Highley), instead of being life-size, are reduced by a third, thus making a convenient and portable volume. It is unnecessary to insist on the extreme value, from an educational point of view, of pictures and diagrams of anatomical parts, though we should be sorry ever to see them usurp the domain of practical dissection. An inspection of Parts I and II shows the plates to be most carefully drawn, and their excellence and artistic finish leave nothing to be desired. The work is published by Whitaker and Co., and the cost is about ten shillings for each part.

ATLAS OF CLINICAL MEDICINE.

We have received Part III, Vol. II, of Dr. Byrom Bramwell's "Atlas of Clinical Medicine" (T. and A. Constable, Edinburgh) which is largely devoted to the clinical feature and pictorial appearances of exophthalmic goitre and acromegaly. The photogravure and outline illustrations give a very clear idea of the deformities associated with these two diseases and in both, the context constitutes a complete and in many respects admirable monograph. Two plates and a corresponding amount of letterpress are devoted to the outbreak of "general exfoliative epidemic dermatitis" described and named by Dr. Savill, late Superintendent of the Paddington Infirmary, with the appearance of which many of our readers must by this time be familiar. The part concludes with a case (illustrated) of unilaterial hypertrophy of the face, as remarkable, not to say unique, in its way as it is deforming. We hope we may infer from the continued issue that this magnificent work has received due support at the hands of the medical profession.

A NEW ENCYCLOPŒDIA OF MEDICINE.

Max Merlin, of Vienna, is issuing in sections a "Bibliothek der gesammten Medicinischen Wissenschaft für Praktische Aertze und Specialaerzte." We have received sections to end of the first volume, and so far it promises to be a complete encyclopædia, giving a comprehensive and exhaustive description of every disease and drug at present known to the profession by the best German authors, each article being arranged alphabetically for easy reference. It is under the editorship of Prof. Drasche, of Vienna, whose literary ability and taste can be traced in its pages. The entire work is divided into two parts. The first comprehending internal medicine, children's diseases, midwifery, and gynæcology; the second, pharmacology, toxicology, and chemistry. The whole work is expected to reach eight or ten volumes, each containing 15 or 20 parts. The first volume is now finished, and when the entire work is complete we doubt not it will fulfil the promise made in the initial section of being the most perfect encyclopædia of medical science in the German language.

THE CHILDREN'S WARD.

The "Tales of the Children's Ward," by Honnor Morten and H. F. Getten (Sampson Low, Marston & Co.), comprise a baker's dozen of unpretentious little sketches illustrating various phases of the existence of a hospital nurse, and introducing sundry characters from among the "small fry" of the East End. They are well written, in a simple pleasing strain, and advantage is taken of the opportunity to direct attention, though in no hostile spirit, to details of hospital administration which admit of improvement. The hospital nurse, of course, is represented as an almost ideal creature, and great as are her merits the authoresses have certainly decked her with an unnecessary amount of literary finery. The tales are well calculated to excite the enthusiasm of unoccupied young ladies who become precociously *blasé* and sigh for sights more stirring than the drawing room or "at home" afternoons, or the Park on Sundays. Even the amiabilities and the troubles of nursing life assume a halo of romance in the hands of the writers, while the more painful incidents of the hospital ward are rendered curiously exciting and even morbidly attractive.

◆

Novelties.

A NEW ANTIPYRETIC—"MALAKINE."

We have received from Messrs. Woolley, Sons, and Co., of Manchester, a sample of the new antipyretic and analgesic known as "Malakine." This is a light, canary-yellow, crystalline powder, insoluble in water, and consequently devoid of taste. Malakine is closely related to phenacetin, in fact, it results from the combination of phenetedin with salicyl-aldehyde. In doses of 15 grains and upwards it exerts a marked effect in lowering the febrile temperature, and this too without giving rise to any disquieting symptoms in respect of respiration and circulation. Its analgesic and antithermic effects in acute rheumatism are said to be strictly analogous to those of the salicylates, over which it is claimed to possess the unquestionable advantage of not upsetting the stomach. Its administration, moreover, is not followed by excessive perspiration or noises in the ears. We would specially recommend its use in febrile conditions associated with tuberculosis; it constitutes, moreover, an addition to the therapeutical arsenal in migraine, neuralgia, &c. Owing to its being insoluble in water, malakine is best given in the form of *cachets*, beginning with doses not exceeding 15 grains.

KINGZETT'S IMPROVED SULPHUR FUMIGATING CANDLES.

This convenient contrivance, which has for object to facilitate the fumigation of infected habitations, &c., consists of a mass of sulphur contained in a moulded tin receptacle with appropriate arrangements for lighting and maintaining perfect combustion. This is obtained by inserting Brussels net as a wick, which has been chemically treated, and which not only takes fire very readily, but secures an adequate supply of atmospheric oxygen for the incandescent mass. These "candles" are, we understand, largely used by many of the local sanitary authorities for the fumigation of infected rooms and dwellings, infectious diseases hospitals, &c.; they may be also very usefully employed for the extermination of insect pests. In addition they are eminently suitable for use in various trades, as, for example, by brewers for the fumigation of their vats and tuns in order to free them from troublesome secondary ferments, while again for example they can be most usefully employed for the purification of slaughterhouses and butchers' storerooms. The risk of fire is reduced to a minimum, and we can conceive of no more convenient or efficacious means of securing perfect disinfection than these candles afford.

NEW "TABLOIDS."

We have received a fresh batch of tabloids from Messrs. Burroughs, Wellcome and Co., several of which appear to merit special mention. Among the number we may refer to:—

Dermatol Tabloids.—Dermatol, as many of our readers are probably aware, is a basic gallate of bismuth. It was first introduced as an inodorous, non-toxic and efficient substitute for iodoform, but it has been found very useful by internal application in the treatment of gastric catarrh and ulceration, and also in cases of intestinal catarrh. Given in the form of tabloids, which promptly disintegrate, it exercises a soothing and antiseptic effect on the disorganised mucous membrane.

Alumnol Tabloids.—Alumnol, we are told, is a sulphonic acid salt of aluminium. It is readily soluble in water, and possesses very penetrating and astringent properties which adapt it for use in gonorrhœa and in various cutaneous diseases.

Iodopyrin Tabloids.—Iodopyrin consists of antipyrin in which one atom of hydrogen is replaced by iodine. In the stomach iodopyrin splits up into iodine and antipyrin and this decomposition gives the key to its therapeutical effects.

Benzosol Tabloids.—Benzosol is a benzoate of guaiacol. It is both odourless and tasteless, and is reputed to exert a specific influence as against tubercular disease, akin to that well-recognised attributes of creasote and guaiacol. It checks the exhausting night sweats, disinfects the sputum, and improves the general health of the sufferer.

Hypnol Tabloids.—Hypnol is a compound of chloral hydrate and antipyrin, and it possesses, as its chemical constitution would lead one to infer, valuable hypnotic properties. It is especially useful when the insomnia is due to pain of neuralgic (periodic) character, and especially in the class of cases in which the pain or migraine supervenes when the patient retires to rest, also in insomnia associated with a raised temperature as in tuberculosis, &c.

Agathin Tabloids.—Agathin appears to be a valuable addition to the list of anti-neuralgic remedies—in other words, it belongs to the series of analgesics, It is reported to be free from toxic properties and not to give rise to any disagreeable after effects.

Ipecacuanha Tabloids.—We must also mention the tabloids of powdered ipecacuanha from which the emetic principle has been abstracted in order to allow of the administration of large doses of the drug in dysentery and tropical diarrhœa without the disagreeable nausea which necessarily follows the exhibition of the crude drug. Each tabloid contains five grains of the compressed powder.

The Lanoline Soap series has been added to by the introduction of a "Lanoline Pine-Tar Soap," which, to the now well-recognised properties of lanoline, adds the mildly stimulating and antiseptic properties of wood-tar. It is elegant enough for a toilet soap, and active enough for medicinal purposes.

We have also received from Messrs. Burroughs and Wellcome a sample of their "Oil of Eucalyptus." It is stated to be obtained by distillation from the leaves only of the *Eucalyptus Pleosa*. The preparation is highly charged with eucalyptol, and is altogether one of the best of the kind which has come under our notice.

◆

Medical News.

London and Counties Medical Protection Society.

A meeting of the Council of this Society was held on the 27th February, under the presidency of Dr. G. A. Heron, F.R.C.P. It was decided to remove the Registered Offices after 31st inst. to 12 New Court, Lincoln's Inn, London. Messrs. Le Brasseur and Oakley, of the same address, were appointed solicitors to the Society. A standing "Legal Committee," consisting of ten members, was appointed, to whom matters of a legal or defensive character will be submitted. A committee was also formed for the object of watching Parliamentary proceedings interesting to medical men. A vote approving the prosecution of the Indian oculists was unanimously passed. The question of changing the commencement of the Society's year from May 1st to January 1st was discussed, and a resolution was passed directing the Legal Committee to revise and consider the existing articles of association and report thereon to the meeting of Council in April next. The list of candidates for membership was approved, and all were elected.

Dr. Theodore Thomson has been appointed by the Local Government Board to conduct the inquiry into the proposed erection of an Infectious Diseases Hospital for Richmond on Hounslow Heath.

The International Medical Congress at Rome.

The Hon. Secretary for England, Mr. G. H. Makins, asks us to announce that the South Eastern and the London, Chatham, and Dover Railway Companies have agreed to issue tickets to guests accompanying members at the same rates as to members themselves. The Secretary-General (Prof. Maragliano) has forwarded documents for identification on the journey to all enrolled members; those who have by mistake not yet received the above documents should apply for passes, instructions, &c., to the Secretary to the English Committee, Mr. G. H. Makins, 47 Charles St., Berkeley Sq., London, W. The Secretary to the English Committee issues passes, &c., only to members of the medical profession and their relatives. Persons wishing to join the Congress under Statute 17, as being interested in one of the sections, must apply direct to *The Secretary General, XI International Medical Congress, Rome.*

Medical Society of London.

The following Fellows were elected office-bearers of the Society at the General Meeting held on Monday last (March 5th):—President: Sir William Bartlett Dalby. Vice-Presidents: Dr. Frederick T. Roberts, Mr. Frederick Treves, Dr. Sidney Coupland, and Mr. Henry Hugh Clutton. Treasurer: Mr. Arthur Edward Durham. Librarian: Dr. William Henry Allchin. Honorary Secretaries: Mr. Charles B. Lockwood and Dr. Amand Routh. Honorary Secretary for Foreign Correspondence: Dr. Heinrich Port. Council: Mr. William Anderson, Mr. Henry Frederick Bailey, Mr. W. Mitchell Banks (Liverpool), Mr. Howard Barrett, Mr. William Henry Bennett, Dr. John Syer Bristowe, F.R.S., Mr. G. Buckston Browne, Mr. John Cahill, Mr. F. Swinford Edwards, Mr. E. Hurry Fenwick, Dr. Archibald E. Garrod, Dr. F. de Havilland Hall, Dr. Frederick W. Hewitt, Dr. Edward D. Mapother, Dr. William Marshall, Mr. William A. Meredith, Dr. H. Montague Murray, Dr. Edward J. Nix, Dr. William Pasteur, and Dr. Charles H. Ralfe.

St. Thomas's Hospital.

The following have been selected as House Officers from Tuesday, March 6th, 1894:—Resident House Physicians: A. E. Russell, L.R.C.P., M.R.C.S. (extension); W. J. C. Merry, M.A., M.B., B.Ch.Oxon. Non-Resident House Physicians: F. Pershouse, L.R.C.P., M.R.C.S.; C. W. Windsor, M.A., M.B., B.C.Cantab. House Surgeons: S. W. F. Richardson, L.R.C.P., M.R.C.S.; E. M. Hainworth, B.Sc.Lond., L.R.C.P., M.R.C.S; A. R. O. Milton, L.R.C.P., M.R.C.S.; G. W. Thompson, B.A., M.B., B.C. Cantab., L.R.C.P., M.R.C.S. Assistant House Surgeons: J. W. Hewett, L.R.C.P., M.R.C.S.; H. A. Dickson, L.R.C.P., M.R.C.S.; Obstetric House Physicians: Senior, T. W. Hicks, L.R.C.P., M.R.C.S.; Junior, C. S. Jaffé, M.B., B.S.Lond., L.R.C.P., M.R.C.S. Clinical Assistants in the Special Departments—for Diseases of the Throat: G. J. Arnold, L.R.C.P., M.R.C.S. (extension); A. W. Cuff, B.A.Cantab., L.R.C.P., M.R.C.S.; Skin, W. B. Winston, B.Sc.Lond., L.R.C.P., M.R.C.S. (extension); J. R. Carver, M.A., M.B., B.C. Cantab.: Ear. C. W. Cooke, M.D.Lond., L.R.C.P., M.R.C.S.; A. M. Collcutt, M.A., M.B., B.C.Cantab., L.R.C.P., M.R.C.S.

OPERATION DAYS AT THE LONDON HOSPITALS.

MONDAY—Hospital for Women, 2 p.m.—Metropolitan Free, 2 p.m.—Royal London Ophthalmic, 10 a.m.—Royal Orthopædic, 2 p.m. —Royal Westminster Ophthalmic. 1.30 p m.—St. Mark's, 2 p.m. — Chelsea Hospital for Women, 2 p.m. — King's College, 2 p.m

TUESDAY—Cancer Hospital, Brompton, 2 p.m.—Guy's 1.30 p.m.—St Mark's, 2.30 p.m.—Royal London Ophthalmic, 10 a.m.—St. Mary's, 1.30 p.m.—Royal Westminster Ophthalmic, 1.30 p.m. - Westminster, 2 p.m.—West London, 2.30 p.m.—Gordon Hospital for Fistula, &c., (Vauxhall Bridge Road), 2.30 p.m.

WEDNESDAY—Children's Hospital, Gt. Ormond St., 9·30 a.m.—Great Northern, 2 p.m.—London, 2 p.m.—Middlesex, 1 p.m.—National Orthopædic, 10 a.m.—Royal London Ophthalmic, 10 a.m.—Royal Westminster Ophthalmic, 1. 0 p.m.—Samaritan Free Hospital for Women and Children, 2.30 p.m.—St. Bartholomew's, 1.30 p m.—St. Peter's, 2 p.m.—St. Thomas's, 1.30 p.m.—University College, 2 p.m.

THURSDAY—Central London Ophthalmic, 1 p.m.—Charing Cross, 1 p.m.—Hospital for Diseases of the Throat, 2 p.m.—Hospital for Women, 2 p.m.—London, 2 p.m.—North-west London, 1.30 p.m.—Royal London Ophthalmic, 10 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. George's, 1 p.m.—Chelsea Hospital for Women, 2 p.m.

FRIDAY—Central London Ophthalmic, 2 p.m.—East London Hospital for Children, 2 p.m.—Guy's, 1.30 p.m.—Royal London Ophthalmic, 10 a.m—Royal South London Ophthalmic, 2 p..m —Royal Westminster Ophthalmic, 1.30 p.m.—St. Thomasn (Ophthalmic Department), 2 p.m.—West London, 2.30 p.m.

SATURDAY—Children's Hospital, Gt. Ormond St., 9.30 a.m.—Cancer Hospital, Brompton, 2 p.m., King's College, 1 p.m.—London, 2 p.m.—Royal Free, 9 a.m. and 2 p.m.—Royal London Ophthalmic, 10 a.m.—Royal Westminster Ophthalmic, 1.30 p.m.—St. Bartholomew's, 1.30 p.m.—St. Thomas's, 1.30 p.m.

Notices to Correspondents, Short Letters, &c.

☞ Correspondents requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

Original Articles or Letters intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

N. M.—We are always pleased to publish announcements of births or deaths in the families of subscribers free of cost, but we do not undertake to copy them from our contemporaries.

A NEW MEDICAL PRACTITIONERS' ASSOCIATION.

We read in our contemporary the *Financial Times* that there was registered on the 15th ult. the "Incorporated Medical Practitioners' Association," with a membership of 500, each of whom is liable for £1 1s. in the event of winding-up. Objects: To protect the interests of medical practitioners. Is this another Association framed on the lines of the already existing Defence Unions? No prospectus, so far, has reached us of this new company, nor have we heard anything about it.

A. S. G.—The blocks have been received, and will be dealt with as desired. You will receive proofs for correction in due course.

L. P. D.—The meeting was private and unofficial, and no formal announcement of its being held was therefore deemed necessary.

MEDICAL FEES TO DENTISTS.

Ignoramus asks: Is there any rule with reference to the charging, or otherwise, of fees to dentists by medical practitioners, or *vice versâ*?

[There is no rule, and the practice is a matter of taste. As a general rule, medical practitioners do not take fees from recognised dentists, and dentists accept from medical practitioners only such payment as will recoup them for outlay. It ought, however, to be recollected that the expenditure of time, labour, and material by a dentist is very much greater than by a medical practitioner, and that circumstance ought to be recognised by a small fee or a present.—Ed.]

Meetings of Societies, Lectures, &c.

WEDNESDAY, MARCH 7TH.

London Post-Graduate Course.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. C. Theodore Williams: Diagnosis of Pulmonary Tuberculosis. Royal London Ophthalmic Hospital, Moorfields.—At 8 p.m, Mr. A. S. Morton: Ocular Paralyses. Hospital for Skin Diseases, Blackfriars.—At 1 p.m, Dr. Payne: Ringworm and Vegetable Parasitic Diseases.

Obstetrical Society of London.—At 8 p.m. Specimens will be shown by Dr. William Duncan, Dr. Leith Napier, and others. Dr. R. P. Harris: A Plea for the Practice of Symphyseotomy, based upon its Record for the passed Eight Years (communicated by Dr. Lewers)—Dr. Gow: The Relation of Heart Disease to Menstruation.

West London Hospital (Hammersmith).—At 5 p.m., Dr. Aldren Turner: Some Syphilitic Spinal Lesions. (Post-Graduate Course.)

THURSDAY, MARCH 8TH.

British Gynæcological Society.—Specimens:—Mr. Jessett: (1) Uterus removed per vaginam for Malignant Disease; (2) Uterus removed per vaginam for Multiple Fibroma.—Dr. Purcell: (1) Uterus removed per vaginam; (2) Portion of Uterus removed by supra-vaginal Amputation, both for Malignant Disease. Paper by Dr. Macnaughton Jones: A Gynæcological Question of Importance in Forensic Medicine relating to the Hymen.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street.—At 3.30 p.m., Dr. Lubbock: Selected Medical Cases. National Hospital for Paralysed, Bloomsbury.—At 2 p.m,. Mr Victor Horsley: Surgery of the Nervous System. Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Mr. John Hopkins: Cases in the Wards.

Ophthalmological Society of the United Kingdom.—At 8.3) p.m. Living and Card Specimens at 8 p.m. Mr. Spencer Watson: A case of Interstitial Keratitis with intense Photophobia and Sneezing in a Man of thirty-one years.—Mr. J. B. Lawford: Peculiar Pigmentation of Iris and Conjunctiva.—Mr. H. Work Dodd: A case of Coloboma of Iris and Choroid, with Remains of the Hyaloid Artery.—Mr. Juler: A case of Unilocular Optic Neuritis.—Mr. Cowell and Mr. John Griffith: A case of Circumferential Folding of the Periphery of the Iris with Detachment of the Retina.—Mr. Priestley Smith: Snellin's Shield for Protection of Eye after Operation. Continuation of the Discussion on Mr. Jonathan Hutchinson's paper on School Ophthalmia. Mr. Hill Griffith: Some cases of Orbital Tumours.—Mr. R. Williams: (1) A case of Rapidly Growing Tumour of the Orbit; (2) A case of Epicanthus (with photographs); (3) A case of Double Optic Neuritis.

North London Medical and Chirurgical Society.—At 9 p.m., Dr. Patrick Manson: The Diagnosis of Tropical Diseases seen in London (with lantern illustrations),—Mr. Evans Jones: Tubal Pregnancy—Rupture—Abdominal Section—Recovery.

FRIDAY, MARCH 9TH.

Clinical Society of London.—At 8.30 p m., Mr. Mansell Moullin: A case of Cerebral Abscess.—Mr. Battle: Three cases of Extra-dural Hæmorrhage.—Mr. C. B. Lockwood: Excision of Part of a Dislocated Internal Semilunar Fibro-cartilage of the Knee; Account of Result Twenty-one Months afterwards.—Dr. W. Cayley and Mr. Bland Sutton: A case of Perforation of the Bowel in Typhoid Fever treated by Washing Out the Peritoneal Cavity and Excising the Perforation.—Mr. Christopher Heath: Two cases of Rectangular Ankylosis of the Hip-joint treated by Operation.

London Post-Graduate Course.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. C. Theodore Williams: Varieties of Pulmonary Cavities.

Vacancies.

Bradford Children's Hospital.—House Surgeon. Salary £70 per annum, with board, residence, and washing. Applications and testimonials to the Secretary by March 12th.

Carmarthen Joint Counties' Lunatic Asylum.—Medical Superintendent. Salary £500 per annum, with unfurnished house, washing, &c. Applications and testimonials to the Clerk to the Visitors by 24th March.

County Asylum, Prestwich, Manchester.—Assistant Medical Officer (unmarried). Salary £100 per annum, increasing to £200, with apartments, board, attendance, and washing. Applications to the Superintendent.

Miller Hospital, Greenwich.—Junior Resident Medical Officer. Salary £3) per annum, with board. Applications by March 10th to the Hon. Secretary, from whom particulars can be obtained.

Royal South Hants Infirmary, Southampton.—House Surgeon. Salary £100 per annum, with board and lodging. Applications to the Secretary by March 10th.

Sheffield Public Hospital.—Assistant House Surgeon, also a Junior Assistant House Surgeon. Salary £65 and £50 respectively, with board, lodging, and washing. Applications to Dr. Sinclair White by March 12th.

Tunbridge Wells General Hospital.—Resident House Surgeon. Salary £100 per annum, with board, &c. Applications to the Assistant Secretary at the General Hospital by March 13th.

Appointments

Knight, E., M.R.C.S., L.R.C.P., Junior House Surgeon to the Salford Royal Hospital.

Lodge, S., jun., M.D.Durh., Special Assistant Surgeon to the Bradford Eye and Ear Hospital.

Macevoy, H. J., M.D., B Sc.Lond., Honorary Medical Officer to the Kilburn and St. John's Wood General Dispensary.

Muir, R. D, L.R.C.P.Lond., M.R.C.S., Medical Officer to the Out-patient Department, Miller Hospital, Greenwich.

Nevins, J. E., M.B.Lond, M.R.C.S., Honorary District Medical Officer to the Ladies' Lying-in Charity of Liverpool.

O'Sullivan, Dr. M., Pathologist and Anæsthetist to the Children's Hospital, Temple Street, Dublin.

Palmer, J., L.K.Q.C.P., L.M., L.R.C.S.Irel., Health Officer for Mundoora, South Australia.

Paterson, D. R., M.D., M.R.C.P.Lond., Honorary Physician to the *Hamadryad* Seaman's Hospital, Cardiff.

Sandall, T. E., B.A.Cantab., M.R.C.S., L.R.C.P., House Surgeon at Charing Cross Hospital.

Shears, C. H. B., L.R.C.P.Lond., M.R.C.S.Eng., Surgeon to the Liverpool Eye and Ear Infirmary.

Taylor, G. C., M.A., B.C.Camb., Senior House Surgeon to the Infirmary for Children, Liverpool.

Tomlinson, W. R., L.R.C.S.Irel, Medical Officer of the Townsville Medical Union, Queensland.

Unitt, J. A., L.R.C.P., L.M.Ed., M.R.C.S., Medical Officer for the Quorndon Sanitary District of the Barrow-upon-Soar Union.

Whitfield, D. W., M.R.C.S., L.R.C.P.I., Medical Officer and Public Vaccinator to the Ironbridge District of the Madeley Union.

Marriages.

Kennedy—Cox.—Feb. 28th, at Foggyley, Dundee, James Martin Kennedy, M.D., Aberford, Leeds, to Annie Elizabeth, second daughter of William Cox, of Snaigow, Dunkeld.

Mortimore—Hudson.—March 1st, at St. James's, Camberwell, James Anning, M.R.C.S., L.R.C.P., to Maud Mary, fourth daughter of Augustine Henry Hudson.

Deaths.

Edwards.—March 1st, at Fairfield House, Kingsclere, Septimus Edwards, M.R.C.S., aged 68.

Holt.—Feb. 27th, at Savile Row, London, W., Barnard Wight Holt, F.R.C.S., aged 77.

Jacob.—March 1st, at 12 Park Street, Leeds, Ernest Hy. Jacob, M.A., M.D., aged 44.

O'Reilly.—March 4th, at 13 Cambridge St., Hyde Park, W., the infant son of Brigade-Surgeon Lieut.-Colonel T. O'Reilly, Army Medical Service.

Orr.—Feb. 23th, Surgeon-General Geo. Frederick Orr, Madras Army, Retired, aged 43.

Savile.—Feb. 23rd, at Nafferton, Hull, Robert Savile, M.D.Edin., M.R.C.S., aged 60.

Vinen.—Feb. 23rd, at Gordon Road, Ealing, Edward Hunt Vinen, M.D, F.L.S., aged 79.

Wheeler.—Feb. 26th, at 11 Museum Terrace, Chelmsford, Daniel Wheeler, M.R.C.S.Eng., L.S.A., aged 75.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

Original Communications.

THE ADMINISTRATION OF ANÆSTHETICS CLINICALLY CONSIDERED (a).

By JOSEPH WHITE, F.R.C.S Ed.
Nottingham.

ABOUT 40 years ago, I laid before the Nottingham Medico-Chirurgical Society an analysis of several hundred cases of chloroform administration, and shortly afterwards I read at the Leicester meeting of the Midland Branch of the British Medical Association a paper "On the Action of Chloroform" which was published in the *British Medical Journal*, in June, 1857.

In those two papers I endeavoured to give as far as I then knew, a short exposition of the physiological action of chloroform and other anæsthetics. Some of the views which were then advanced, a longer experience has led me to modify, whilst in others a wider and longer observation has but enabled me to confirm them.

I did not keep a permanent record of my earlier cases, but up to the present date the number of cases of which I have kept very brief but accurate notes amount to 7,055, viz., chloroform, 4,049; ether, 798; nitrous oxide, 691; methylene bichloride, 79; amylene, 5; A.C.E. mixture, 1,433; which I have almost entirely used for many years.

I have therefore thought that after this lengthened period of time it might be of interest if I were to submit for your consideration some of the conclusions which more extended observations have enabled me to form.

It is now so many years since the introduction of anæsthetics in surgical practice that I am afraid but few of us can remember the intense interest with which they were received, and if time had permitted I might have glanced for a few moments (I think profitably even now) at that epoch in the history of surgery as it fell under my own observation during the years of '47 and '48; for it is curious to look back to the days of the first employment of ether, and to call to mind the varied and contradictory effects which were attributed to it even by the leaders of the profession.

I was just about leaving Edinburgh in the early part of '47 when Simpson made his first experiments with anæsthetics which led to his introduction of the use of chloroform.

On the 19th of January (just a month after the first use of ether as an anæsthetic in England) Dr. Simpson administered it in a case of labour and found that it was capable of relieving the uterine pains without interfering with the process of parturition. He employed it largely with almost uniform success, and in the medical periodicals of the time he strongly advocated its use. He was, however, dissatisfied with the objectionable smell and exciting effects of ether, and he sought for an anæsthetic which, if possible, should be more easily administered, and after various trials he found it in the then little-known substance chloroform.

The advantages claimed for chloroform by Simpson were generally admitted, *except as regarded its supposed safety.*

Several cases presenting dangerous symptoms were soon reported, and on the 28th of January, '48, the first case of death clearly attributable to chloroform occurred in the neighbourhood of Newcastle, and which at the time caused the greatest interest and excitement. This was the case of Hannah Greener a healthy girl of 15, to whom chloroform was administered for the removal of a toe-nail. About a teaspoonful of chloroform was given on a folded napkin, and the patient *was seated in a chair by the fireside.* The death was sudden and the time that elapsed from the first inhalation to death was under three minutes. Post-mortem examination revealed no disease except slight congestion of the lungs and an empty condition of the left cavities of the heart.

In the next month, on the 23rd of February, a second death, under similar circumstances, was reported from Cincinnati, in America. This was the case of a healthy woman, æt. 35, who went to a dentist's to have two or three stumps of teeth removed, had about ʒij of chloroform administered whilst seated in a dentist's chair and in two minutes was dead.

Here again on post-mortem examination all organs were found healthy, except a slightly congested condition of lungs, with a flaccid state of heart and an empty condition of all its cavities.

Various explanations were attempted to be given of the cause of these deaths, and blame was attributed to the mode of administration and to the want of experience in the administrator.

On the 30th of June, however, a case occurred which at once aroused the apprehension of the profession to the great danger attending the use of chloroform even in practised hands.

One of the earliest and most extensive administrators of ether and chloroform (I think he was the first who gave ether successfully in this country) was Mr. Robinson, a dentist in Gower Street, who had written largely upon their use, and who, it was stated, had himself administered anæsthetics in dental and other operations between 3,000 and 4,000 times.

On the 30th June, '48, Mr. Walter Badger, of Rotherham (a young solicitor, æt. 22, and son of one of the coroners for Yorkshire) called upon Mr. Robinson to have two or three stumps extracted, and wished to have chloroform. He was seated in the dentist's chair and had about 1½ drachms of chloroform given to him—and in less than one minute he was dead.

At the post-mortem the lungs were found perfectly healthy, but the heart was fatty, especially at its apex, and the liver was considerably enlarged.

In all these early cases of death under chloroform it was to be noted (and for *this* reason I have been anxious to refer to them here) that death took place without any warning, very soon after the commencement of inhalation, and when the patient was in a *sitting* posture; and that the operations were of a trifling kind.

During the next few months other cases of death under chloroform were, from time to time, reported—2 more in England, 2 in France, 1 more in the United States, and 1 in India, occurred during the first year of its use—all as sudden, and all unexpected; all for trifling operations; and all in apparently healthy people.

(a) Abstract of Paper read at the Medical Society of London, Feb. 19th, 1894.

Post-mortem examinations revealed no morbid changes other than congested lungs (sometimes very slight), and a flaccid and partially empty condition of heart.

Great efforts were therefore naturally made to investigate both experimentally and clinically the physiological action of chloroform; and one of the most assiduous investigators was the late Dr. Snow, whilst important experiments on its action were made at the same time by several others.

The effects of chloroform (and of most other anæsthetics also) as observed in ordinary cases of inhalation, may I think, be practically divided into four stages:—

1. The period of continued consciousness.
2. „ semi-consciousness.
3. „ sleep.
4. „ coma and threatened death.

In the 1st period, according to the above division, a patient will generally retain perfect consciousness of all that is going on around him for some little time after administration has commenced. He will tell you his sensations, and will frequently inform you that the anæsthetic is failing in its effect, for he feels no difference. In this stage the pulse is generally quickened and sometimes feeble—the face flushed—the respiration hurried for a few moments, then slow, and sometimes voluntarily suspended, but the patient still perfectly understands all that is said to him.

Even this preliminary stage is not free from danger, and in most of the *early* cases of death from chloroform it occurred in this stage. In the case of Mr. Badger, he died in less than one minute from the commencement of inhalation, and during a state in which he had been perfectly conscious up to a few seconds before his death. He remarked to Mr. Robinson, "It is very pleasant," his hand and head dropped, and he was dead. Such was the case also in other of the deaths. In Dr. Snow's table of 50 examples of the earliest deaths under chloroform, 9 of the patients died within the minute after the commencement of inhalation, and 4 of them within a few seconds.

In this stage too, the element of *fear* may become a very important factor. A patient, in face of an operation, knows, and not unfrequently overestimates, his danger; and he may (I will not say frequently, for it is really surprising how seldom such occurs even in the most nervous people) approach the operation in an almost fainting condition from sheer dread. A fainting heart, fainting already from sustained nervous tension, faints outright in the preliminary stage of narcotism, and a very small quantity of chloroform may under such conditions prove fatal. Several deaths of this kind have been reported; and though I have never seen a death occur under these (or any other) circumstances, I have seen *several* cases in which most alarming syncope has occurred—purely the result of fear—and hence the great importance of promoting to the utmost of our power the confidence and courage of a patient in the prospect of an operation.

With the commencement of the *second* period, consciousness becomes clouded. A dreamy state occurs in which a patient may become talkative, incoherent, excited—and will frequently struggle, sometimes violently. He will raise himself upon the bed in spite of every effort to restrain him, and his face will be flushed or livid from his exertion. He will hold his breath for several seconds, and then fall back upon his bed, prostrate and almost pulseless. It is not surprising therefore, to be told that in *such* condition danger and even death may supervene. A considerable number of the deaths recorded have been in this period of administration, and it was only a few months ago that such a death occurred in one of the hospitals in the South of England.

In this stage also, though generally a little later on, *sickness* will very frequently occur, almost *certainly*, unless care has been taken to cause the patient to abstain from food for 3 or 4 hours previous to inhalation.

There are, I think, few symptons that are more trying to the administrator than this sickness under chloroform. The great and sudden prostration, the rapid failure of pulse, the blanched countenance with the profuse clammy perspiration, indicate a condition of syncope which is always a very anxious one. This sickness moreover, generally comes on just as a patient is becoming unconscious, and just as an operation is about to be commenced. The sickness thoroughly rouses him to sensibility, though in a state of great collapse, and after a brief interval of rallying, during which vomiting again and again occurs, inhalation has to be cautiously renewed:—and of course under very unfavourable conditions.

At the *end* of this second period a remarkable set of symptoms occur. The patient gradually becomes tranquil—the breathing becomes regular, natural in depth and frequency, and the pulse general firmer and of normal rate.

He is now *un*conscious of what is passing, but may be readily aroused, and the conjunctival reflex is still active. The eyelid if raised falls again, and the eyeball slowly rolls from side to side. The pupil (and this I look upon as a most important guide) which up to this time has generally somewhat dilated, now gently oscillates between dilatation and contraction, and these remain contracted almost to a point. If, when the pupil is thoroughly contracted, the eyelid now be raised, it does *not* fall again, and the eyeball is perfectly motionless. The conjunctival reflex is *completely* abolished, and the patient passes into a condition of *perfect sleep*.

(This oscillation and contraction of the pupil which accompanies the abolition of the conjunctival reflex I look upon as an almost unerring guide. I have not found it fail in 1 per cent. of my cases.)

I have termed this third period "The period of Sleep." I believe it is a condition of *perfect* sleep—a condition analogous to that of *natural* sleep—except that so long as the action of the anæsthetic is maintained the patient cannot be awakened *suddenly*.

In this condition an operation, however painful, may be painlessly performed; and by assiduously and carefully watching the state of the respiration, of the pulse, and especially of the *pupil*, I believe that this condition, when once attained, may be prolonged almost indefinitely, and with very little danger.

Unfortunately we know little of the true physiology of natural sleep and, notwithstanding the various theories which have been at different times advanced, we still know *very* little of its causes; but the researches of different observers during the last few years have taught us so much of its *objective* signs that I think we may, in this way, fairly compare it with what we observe in the narcosia of anæsthesia.

In *natural* sleep, of course, the nervous system, as a whole, falls into a quiescent condition. Its functions are curtailed and some of them abolished; whilst those which persist are carried on in a modified manner, and in a diminished degree.

The psychical centres in the convolutions of the brain, so active during waking moments, are in sleep at rest; and consciousness and volition are in abeyance.

In *natural* sleep, also, the motor and sensory centres partake of a like tranquility. The sensory centres become incapable of perceiving slight or ordinary sensations, while their corresponding motor nerves respond in a slow and imperfect way; and the great nervous centres in the medulla oblongata, which are mainly concerned with the carrying on of respiration and circulation are, so far as is compatible with life. asleep.

The spinal cord, too, is less active, and reflex movements can only be produced in response to more powerful excitation than when awake.

In short, the Brain, the Ganglia, the Medulla, and the Cord are gradually thrown into a state of repose; and the functions of life are carried on with the smallest possible expenditure of force.

I have called the fourth period "The period of coma and of threatened death."

If, after obtaining the condition of sleep, we push the administration of an anæsthetic to a still greater degree we produce the following symptoms. The pupil from being fully contracted gradually dilates until it is very widely so, the eyeball remaining fixed and utterly insensible to touch. The breathing becomes stertorous. The respirations become slow, often from 6 to 8 per minute slower than when in the state of sleep; then shallow, irregular, and almost entirely diaphragmatic. The heart acts for a time laboriously, then more slowly, and more and more feebly. The muscles become more and more relaxed, then a profuse cold perspiration, the sphincters lose their power, and death ensues; generally the respiration ceasing before the pulse, but occasionally the pulse and respiration apparently ceasing simultaneously.

In short, the state of sleep of the third stage passes into a state of so-called coma, and death supervenes with symptoms similar to those we observe in apoplexy.

This stage in the human subject of course rarely goes on to death, for the administration would not be likely to be prolonged to a fatal issue, but more than one case has been reported in which death has been clearly attributable to this degree of narcotism.

I have never carried the administration of chloroform far into this fourth stage, except for the reduction of dislocations or for the application of taxis in hernia, but I have even here, although on the active look out for them and endeavouring to guard against them, met with cases showing *most alarming symptoms*, and requiring very prompt treatment for the recovery of the patient.

The course of symptoms, however, *even unto death*, was shown in a marked and unvarying manner in Sibson's experiments upon the lower animals. One of the chief objects of the experiments of Sibson, Dr. Percy, and Dr. Glover, and later on of Snow and Richardson, was to determine if possible whether the deaths from anæsthetics were primarily attributable to interference with respiration, or to failure of the heart's action, and as a consequence, what should be the appropriate means to be adopted in case of accident.

They found that in cases of *rapid* death, *i.e.*, in cases where a *large* dose had been *suddenly* given to an animal and death had followed very quickly after the commencement of administration, the action of the heart was invariably the first suddenly to fail; whereas, in the *slow* and sustained administration of chloroform, the respiration failed first, though at the same time the heart's action was depressed almost to syncope, and Sibson entertained the idea that, as the heart is the first organ of the body to be fed with the blood charged with chloroform from the pulmonary veins, therefore it would be the first organ to succumb under the sudden influence of the anæsthetic, and would, of necessity, feel the influence before the respiratory muscles felt it.

At Sibson's suggestion, in the early part of 1851, I made some experiments upon the difference in the amount of chloroform in the blood after rapid and gradual administration, and found that in an animal killed by the *sudden action of an overdose*, the blood of the carotids and femorals, as estimated by Durvy's process for the detection of chloroform contained little more than two-thirds the amount of that obtained from an animal to which chloroform had been given *slowly*, to the extent of producing *safe* anæsthesia. Death was not the result of the *amount* in the circulation, but of the *sudden* action of a lethal dose.

For more than thirty years, the same question has been attempted to be solved, both by individual workers, and by the combined efforts of authorised committees.

It will be remembered that the Hyderabad Committee arrived at the following conclusions:—

1. That the administration of chloroform is free from all risk provided that the breathing be perfectly regular throughout, and that inhalation be stopped as soon as the subject is fully under its influence.

2. That chloroform *never* causes death by sudden stoppage of the heart.

3. That death from chloroform is always the result of an overdose.

4. That danger of the overdosing is enormously increased by holding the breath; by struggling; or by anything which causes gasping inspirations. And

5. That the inhibitory action of the vagus nerve, which is called into play in threatened or actual poisoning with chloroform is an important safeguard against a fatal result.

Had time permitted I should have been glad to have said a few words on each of these points, but though in the main agreeing with most of the deductions arrived at by the Hyderabad Commission there is one point on which I must very strongly differ from them.

The Commission maintain that it is not only *un*necessary to have regard to the condition of the pulse during the administration of an anæsthetic, but that it is *positively wrong to do so;* as we then divert our attention from the only point of importance—the watching of the respiration.

I also cannot attach too much weight to *the most jealous and constant watching of the breathing;* but I am quite sure that a great, and I believe an *equally* important warning of approaching danger may be gathered from the rapid enfeeblement and flickering which (as far as my own experience has gone) has almost invariably ushered in the crisis of danger.

There need be no difficulty in watching the cirulation at the same time as we watch the respiration during inhalation; and I feel that it would be most dangerous teaching to utterly disregard (as the Commission desire to disregard) the important warning frequently given by the pulse.

CONCLUSIONS.

As I have already suggested, I think we should, as a preliminary step, endeavour by every possible means to encourage a patient in the prospect of an operation —to remove any undue fear—and to render him tranquil at the time of administration.

For three or four hours before the use of an anæsthetic no food should be taken, unless it be a few spoonfuls of liquid nourishment, or vomiting, with its ill consequences is almost sure to take place.

The patient should always, if possible, be placed in an horizontal posture. All tight clothing should be carefully set free or removed, and the neck and chest of the patient relieved of the slightest pressure. The undivided attention of the anæsthetist should be given to the patient during the whole period of administration.

The patient should be kept as quiet and cheerful as possible when inhalation is begun. There should be no noise about him, and he should never be spoken to or disturbed until sleep takes place.

Inhalation should be commenced very gradually, beginning with a free admixture of atmospheric air, and the proportion of anæsthetic vapour slowly increased.

If struggling occurs, we should admit more air or remove the inhaler. When struggling subsides, we should gradually resume the anæsthetic and endeavour to maintain regular breathing until the period of sleep is reached.

We should carefully watch the state of pupil, which is generally that of moderate dilatation until the conjunctiva begins to be insensible. Then the pupil oscillates between dilatation and contraction, and the eyeball slowly rolls in its orbit.

The eyeball then becomes fixed; the conjunctival reflex becomes more and more feeble, and then disappears. The pupil will now be found to be fully contracted, and the condition of *sleep* is attained.

This condition of sleep can be kept up for a considerable time. As soon as there is full contraction of the pupil the inhaler should be removed, and gently reapplied if the pupillary contraction passes off and the eye begins to move. This renewed movement of the eyeball and diminishing contraction of the pupil invariably usher in returning consciousness.

The movements of the pupil and of the eyeball and the conjunctival insensibility, *pass off in an inverse order to that of their accession*, and afford the most accurate guide for any necessary renewal of the anæsthetic.

An operation should never be commenced until this condition of sleep is reached. The slightest disturbance of a patient, either by noise, or by a slight puncture, or by movement, will so rouse him as to render him dreamy and excited, and will generally produce a depressing action both on the respiration and the pulse.

If stertorous breathing should occur, with fixed eye and dilated pupil, inhalation should immediately be stopped.

We should never, if possible, attempt to rouse a patient suddenly from his sleep by slapping, &c. The free admission of air to the apartment, and to the face and cheek of the patient, and if necessary, gentle application of ammonia to the nostrils, are the best restoratives in ordinary cases of *excessive* anæsthesia.

And lastly, we should *most carefully watch the state of respiration and pulse*, and the condition of the pupil and aspect of the countenance during the whole period of inhalation, and if the respiration or pulse fail we should have immediate recourse to artificial respiration, free admission of air, and application of ammonia to the nostrils, and, if necessary, we should gently but regularly maintain artificial respiration for at least half-an-hour.

I may just add that I believe there is, as stated by the chloroform committee of the Royal Medical and Chirurgical Society, a considerable advantage in the use of mixtures of ether and chloroform over that of chloroform alone.

I have for many years employed the A.C.E. mixture almost exclusively, and have given it in nearly 1,500 cases. It is certainly less depressing than chloroform, and not appreciably more irritating to the pulmonary mucous membrane. I have so far never seen any but the most favorable results from its use, and I cannot help feeling that it is decidedly more free from danger than chloroform by itself.

A
FORM OF DYSPHAGIA,
ASSOCIATED WITH CHRONIC ALCOHOLISM.

By ALBERT E. MORISON, M.B., F.R.C.S. Ed., M.C.,
Hon. Visiting Medical Officer, Hartlepool Hospital.

Three cases, suffering from a condition, of which I have seen and can find no description, have come under my care in the past eight years. The three patients were all women, about 60 years of age; all had been in the habit of drinking undiluted whisky for many years; all had the same symptoms, viz., a gradually increasing difficulty in swallowing, solids being first rejected, and subsequently fluids; all terminated in death. In one case I was able to satisfy myself by a carefully made post-mortem examination that no organic obstruction existed in the pharynx or œsophagus; in the other two cases the passage of a full-sized bougie enabled me to exclude organic stricture with certainty. The following are notes of these cases:—

Mrs. N., æt. 60, complains of difficulty in swallowing loss of flesh, and weakness.

History.—She has noticed a difficulty in swallowing solid food for two months, and latterly as soon as any fluid has entered the back of the throat, it causes coughing, and is expelled in a very short time through nose and mouth.

The patient has always been a very healthy woman, is the mother of eight children, the youngest being 18, and has always had to work hard. For many years she has taken whisky regularly, though not in large quantities at a time, and is said never to have been intoxicated by it. Her custom has been to take the *whisky undiluted*, and as much as three or four glasses a day. She has lost almost two stones in weight since the commencement of her illness.

Present State, Nov., 1884.—Patient is a thin emaciated woman who does not appear to be so old as she says she is. On examining the various organs of the body no disease can be detected, the heart, lungs, and liver, and digestive organs being apparently healthy. The tongue is slightly coated and moist. The pharynx appears to be normal; the movements of the soft palate are perfect, and on introducing the finger into the pharynx nothing unusual is detected. A drink of water causes coughing, and is almost immediately expelled through her mouth and nose. On attempting to pass olivary-pointed œsophageal bougie I failed, after a fair trial, to get it past the level of the cricoid cartilage.

Diagnosis.—An opinion to the effect, that the patient was suffering from a stricture of the œsophagus at the level of the cricoid cartilage seemed to me the only one possible. Treatment consisted in the administration of fluid nourishment, milk, beef-tea, oysters, raw eggs, with lemon juice, &c. Under this treatment the patient did not improve, and soon was unable to swallow anything but raw eggs. Several attempts I made to pass a bougie failed, and an effort to introduce a small nasal tube into the stomach was attended by no better success.

In March, 1885, as she was steadily getting feebler and thinner, I suggested gastrostomy, but she refused to have any operation performed. Death from starvation occurred on May 1st, 1885.

Post-Mortem.—The body is exceedingly emaciated. The various organs are apparently quite healthy, there being no macroscopic evidence of disease. The œsophagus, removed entire and slit open, shows no trace of any stricture, narrowing, or infiltration, and looks quite healthy. The mucous membrane of the pharynx is smooth and glazed.

Case 2.—Mrs. B., æt. 67, complains of difficulty in swallowing.

History.—For many years she had to be careful how she took food, as it was apt to get in some "false passage" at the back of the throat, causing her to choke. When this occurred, to obtain relief she was compelled to pass her finger down her throat and produce retching to bring it back. Liquids could be swallowed without discomfort until a few weeks ago. She had been in the habit of taking "whisky neat" for over twenty years, though only in small quantities at a time.

Present State.—April 4th, 1888. Patient is weak and emaciated. All the organs of the body appear to be healthy. Solids stick in her throat, and cause choking. Milk is taken slowly and in sips until about an ounce has been swallowed, when some of it (about one-third) is returned by retching. The finger passed into the throat reveals nothing. The pharynx and soft palate appear normal.

Bearing in mind the previous case, I attempted to pass a full-sized olivary bougie, but it was checked at the level of the cricoid cartilage.

By exerting firm steady pressure for some time, the obstruction yielded, and the bougie passed on into the stomach. It was withdrawn with ease, but the bulbous end was tinged with blood.

Treatment.—For a time I fed the patient with a catheter passed down her œsophagus, but she soon tired of this manner of living, and was satisfied to exist on what fluid nourishment she could succeed in swallowing.

May 19th.—She is confined to bed, and is much emaciated and feeble, for she can swallow nothing without causing cough and suffocation.

May 26th.—After being unconscious for twenty-four hours, she died. No post-mortem obtained.

Case 3—Mrs. T., æt. 59, complains of weakness and difficulty in swallowing.

History.—For sixteen years, since the cessation of menstruation, she has been subject to attacks of *petit mal*, occurring from four to eight times a day, and rarely at longer intervals than a week. For many years she has had a difficulty in swallowing solid food. In January, 1892, owing to excessive weakness, she took to her bed, and has been unable to take any form of solid nourishment. Until fourteen days before her death, she could swallow liquids with comparative ease. She has been accustomed to take brandy or whisky undiluted for sixteen years, but never in large quantities at a time.

Present State.—May 5th, 1892.—Patient, who is confined to bed, is very thin, and has lost over two stones in weight since her illness began. All the organs of the body appear healthy, though her mind is evidently weak. She is only able to take fluid nourishment, and that with difficulty. The pharynx and soft palate appear normal. I tried to pass a full-sized olivary bougie, but in this instance also it was checked at the level of the cricoid cartilage, and only passed on into the stomach after continuous pressure had been applied. As in the last case the bougie was easily withdrawn.

Treatment.—The patient was fed on fluids until within three days of her death. She became comatose and was unable to swallow anything. She died on May 20th, 1892. No post-mortem was allowed.

Remarks.—These cases seem to me worthy of record from the difficulty in their diagnosis. The symptoms, the age of the patients, the obstruction met with, and its position are so suggestive of malignant stricture, that a mistake might readily be made. It is easier to say what it is not the cause of the condition than what it is.

There is no organic obstruction, as proved by the post-mortem examination in Case 1, and the possibility of introducing, with patience, a bougie in the other two cases, yet there is obstruction of a very definite sort, for liquids were retained for a while, and then regurgitated, frequently with force, and the bougie met with marked resistance.

The only explanation that I can offer is that there is inco-ordination with spasm of the muscles concerned in deglutition, chiefly affecting those employed during the third stage, when the tract common to the air and food is passed. Is this due to abnormal afferent impulses conveyed to the deglutition centre produced by alterations in the sensibility of the mucous membrane of the gullet, or by a neuritis affecting the afferent fibres of the nerves forming the pharyngeal or œsophageal plexuses, the result of the imbibition of raw spirits? Such an explanation would seem not to be beyond the bounds of possibility for cases are recorded in which a small ulcer of the œsophagus causing no alteration in the lumen of that tube occasioned such definite obstruction that death resulted from starvation.

Gastrostomy, not necessarily permanent, by giving rest to the irritated tissues, and allowing of the administration of sufficient supplies of nutriment to keep the patient alive for a long enough time to permit of recovery, appears to me to be the best treatment if artificial feeding fails to bring about a rapid improvement, as it did in the cases recorded.

Since writing the above, I have received the following notes of a case that closely resembles the three cases I have described, from Dr. R. Taylor Manson, of Darlington: "I was consulted some months ago by a patient who suffered from severe dysphagia when anything solid was attempted to be swallowed. There was also very severe gastric pain, vomiting and emaciation. For the last ten and a half years, there has been, to my knowledge, a daily and excessive use of whisky. I am not aware, however, that it was drunk absolutely "neat, but certainly with but little water. I saw him several times, and eventually diagnosed stricture of the œsophagus. There was mitral obstruction with cardiac hypertrophy, and the area of hepatic dulness was greatly increased. The pain and dysphagia increased, fluid food was vomited, hæmatemesis occurred, and death.

A post-mortem examination was made, but no stricture of the œsophagus was present."

◆

NOTES ON SOME OF THE ITALIAN SPAS AND HEALTH RESORTS.

By THOMAS MORE MADDEN, M.D., F.R.C.S.Ed.,

Obstetric Physician and Gynæcologist Mater Misericordiæ Hospital; Consulting Physician to the Children's Hospital, Dublin; Hon. President, First International Congress of Obstetrics and Gynæcology, &c.

In view of the approaching meeting of the Eleventh International Medical Congress in Rome, the following notes of my former and more recent visits to several of the Italian summer health-resorts and Spas may probably interest those readers of the Medical Press and Circular who intend then visiting the Eternal City, and may also, perhaps, serve to direct the attention of others to some of the numerous mineral waters of Italy, which are not sufficiently appreciated by British physicians and their travelling patients. These thermal springs, as was long since remarked by Dr. Gardiner, are chiefly met with in the valleys situated on the Mediterranean side of the Apennines, which circumstance is probably connected with the position of the volcanoes and other evidences of subterranean igneous action in that part of Italy.

Commencing our tour through the Italian watering places in Lombardy, the first of these Spas that we meet with is Acqui, an ancient looking town situated on the Bormida in a picturesque mountain district thirty miles from Genoa, within an hour's journey by train from Alexandria, and containing among other vestiges of its former importance a cathedral dating back to the twelfth century, besides remains of far greater antiquity in the Roman Baths and Aqueduct, bearing inscriptions attesting its celebrity from time immemorial as a health-resort. At present, however, the town, though still possessing a population of about 10,000 inhabitants, and containing four thermal establishments and a couple of excellent hotels, has little to attract the visitors beyond the fame of its baths and waters. The latter, which belong to the class of sulphuretted saline springs, originate in the limestone rock and chiefly owe their therapeutic efficacy to the volumes of sulphuretted hydrogen gas, which, together with a small amount of sulphates of soda, lime, and magnesia, oxide of iron, and traces of other salts, they all contain in variable proportions. Of the thermal sources, the warmest, viz., the "Bollente" in the Piazza de Ghetto, has a temperature of 124°, and though deadly sulphurous in odour is perfectly clear and limpid, and so fully mineralised as to be used by the housewives of Acqui for their domestic and culinary purposes. To all the mineral springs of Acqui the observation applies that although inferior in chemical strength to most other mineral waters of the same class they are nevertheless remedies of considerable efficacy in suitable cases when employed in the manner here adopted, viz., mixed with the soil through which they rise, in the form of mud-baths. For this purpose the *humus*, or mineralised peat worked into a semi-fluid consistence is collected in small tanks into one of which the patient enters and lying down is completely immersed, with the exception of the head, in this pultaceous black broth at a temperature as high as it can be borne for about three-quarters of an hour, after which a warm bath of the mineral water is administered. The first effect of these baths is to excite a strong determination of the blood to the surface which becomes so vividly red as to remind the bather of the action of boiling water on a lobster. Soon, however, a profuse perspiration breaks out, which renders it dangerous for the patient to expose himself to the open air for a considerable time after the bath. The therapeutic influence of this application is most evident in chronic rheumatic arthritis, indolent tumours, and intractable cases of secondary syphilis as well as rheumatism. Few but real invalids are to be met with in Acqui, and even of these there are comparatively few foreigners as the town itself offers no inducement for the mere tourist.

II. Abano.—The next Spa in our itinerary is Abano, the birthplace of Livy, now a mere village, which also lies in the same fertile province of Lombardy as Acqui. Small as the place is, the bath establishment and the accommodation for visitors are both excellent. The waters issue from the foot of the Euganean hills, off spurs from the northern declivity of the Apennines, and belong to the class of hot sulphur springs, containing also muriate and sulphate of sodas. There are several sources, the hottest of which has a temperature of 101°. Besides the waters, the mud of Abano like that of Acqui is used medicinally. This *humus* is taken out of the hot springs and having been exposed to the air for a long time, so as to bring it down to an endurable temperature it is used for local and general baths, after which it is alleged, with what truth I know not, that the mud so employed is again returned to the fountain for fresh use. The effects of these mud baths are stimulating and rubefacient, and differ little from the baths of Acqui already described.

III. Pisa.—The mineral waters of Pisa have been used medicinally since the middle of the twelfth century, and the present bath establishments are apparently more than a hundred years built. The thermal source rises from a calcareous spar rock at the foot of Mount St. Julian, where within an area of seventy paces, there are no less than twelve thermal springs which vary in temperature from 106° to 81°. They all belong to the class of thermal saline waters, and leave a calcareous incrustation in the walls, and even in the baths, and a pellicle of the same character consisting of salts of lime and magnesia floats on the surface of the water when left undisturbed in the baths for a day.

The Pisan mineral waters are used internally in cases of jaundice and other hepatic complaints, in chlorosis, in dysentery, and dyspepsia attended with pain. The warm baths are employed in the treatment of gout and rheumatism, impaired power and enlargement of the joints, also in chronic ulcers and skin diseases, and in some obstinate cases of chronic neuralgia.

IV. Lucca.—From Pisa, a journey of less than an hour by the "Strada Ferrata Livornesi," brings us to Lucca, five leagues from which are the baths of the same name. They are situated at the foot of Monte Corsena in one of the prettiest valleys in Tuscany. The watering place itself consists of a long street of handsome hotels, shops, and lodging-houses, and nothing seems left undone to render it one of the most agreeable residences in Italy. There are several bathing establishments in the vicinity of the principal sources, one of which is reserved for the poor gratuitously, and the charges of all are moderate. The supply of water from these sources is very abundant, and they differ little from each other except in temperature, in which they vary from 88° to 133°. The principal mineral constituents of the Lucca waters are the sulphates of magnesia, lime, and alumina, together with smaller quantities of the carbonates and chlorides of the same bases, and also silicate of iron, and traces of iodine and bromine.

Some of the bath-houses of Lucca have been in use since the sixteenth century, when this place was one of the most fashionable Spas in Europe. Since that time the soothing and sedative properties of the mineral waters of Lucca have widely extended their employment in the treatment of cases of chronic rheumatism, leucorrhœa, catarrhal affections of the urinary organs, dyspepsia, and some cutaneous eruptions.

Tuscany contains many other mineral springs, besides Pisa and Lucca, as for instance, Monte Catino, between Lucca and Pistoia. The two principal sources are both muriated saline waters, having temperature respectively of 68° and 86°. They contain sulphates of lime and alumina, muriates of soda and carbonic acid, but in such different proportions that one source, that known as the "Tettucio," is strongly purgative while the other, the "Bagnuola" source is only slightly aperient. The latter is the source generally prescribed, and is used chiefly in chronic enlargements of the liver, over which it exercises a powerful influence resembling that of the Carlsbad Spa. Monte Catino, eighteen miles from Lucca, also possesses thermal saline waters, which are much resorted to in cases of chronic, hepatic, and gastric disorders, dyspepsia, dysentery, gout, and rheumatism, whilst near to Florence are the warm springs of San Casciano, and in the same department, the sulphurous waters of Volterra, with several others.

V. Spas near Rome.—In the *Compartimenti di Roma*, or within the limits of the old Roman states, the only mineral springs which I have had an opportunity of visiting were the warm saline waters of Civita Vecchia and the Campagna, which also abounds in hot sulphurous springs, whilst at Virterbo and Porretta are similar sources, the latter of which may be here briefly referred to. This spa is strongly sulphuretted and highly charged with carburetted hydrogen gas, a circumstance of which the guides often take advantage to startle unscientific visitors by approaching a torch over the well, on which the gas takes fire, and a luminous vapour floats over the water. Besides their sulphurous constituents, the sources of Porretta contain a great quantity of organic matter and salts of lime and soda, with traces of iodine. The taste is bituminous and nauseous, and the temperature varies from 86° to 100°. The action of Poretta water is strongly purgative and diuretic. It is used internally as well as in baths, in the treatment of enlargements and congestions of the abdominal viscera, and in chronic skin diseases.

VI. Neapolitan Spas.—Few readers of The Medical Press and Circular who purpose attending the Roman Meeting of the International Medical Congress will, I trust, fail to avail themselves of the facilities afforded for visiting Naples, which may be reached in five hours by express train from Rome at a cost of little more than a guinea. That fee is one certainly well worth paying, even for the briefest glance at a city that, as I have elsewhere said, has long been esteemed as the *beau ideal* of all that is beautiful in situation or delightful in climate. "Veder Napoli è poi Morir" is a familiar Italian proverb which was well rendered by a too little known medical poet (Dr. Wm. Beattie):—

"Look but on Naples, say her bards, and die!
  Or living, never hope to see again,
Campania's garden, or Salerno's sky—
  So rich in all that maketh monarchs vain,
That schools the sage, or fires the poet's eye,
  And sooth to say who sees her will retain,
In his mind's eye a gorgeous soil and clime,
  The last to vanish with the lapse of time."

As seen from the bay, Naples presents the aspect of a vast triangle, the base of which rests on the shore, and the apex is placed at Capo di Monte. The city is divided into nearly equal parts by the Strada Toledo, or *via* Nazionale and its continuation, the Strada Nuova di Capodimonte, which intersects it for close on three miles. The lower part, formed by small narrow streets, extends towards the eastern side of the bay, and on the other side, which lies above, and parallel to the shore, towards Posilipo, contains the best quarters, the Chiatamone, Santa Lucia, and the Chiaja. The population now amounts to upwards of 500,000 inhabitants.

Nowhere is a clear understanding of the topography of a place more necessary to the study of the climate than in Naples, for in no other place that I am acquainted with does the difference in the exposure of two contiguous quarters effect so marked an alteration in their salubrity. So great indeed are the differences in soil, position, and aspect between the different parts of the city that Naples has been said to possess two perfectly distinct and separate climates, of which the western, or more elevated, part is exposed to the harsh, cold north-west wind, while the eastern side, or that lying along the plain, is protected from the north, but fully exposed to the relaxing, moist and warm southerly winds. One of the advantages which Naples has over some of the Mediterranean health resorts —in other respects, perhaps, better suited for the winter residence of invalids—is the superiority of the living, which is a most important consideration for the valetudinarian. Moreover, Naples contrasts favourably with other places frequented by invalids in the number and variety of resources for passing time agreeably which it possesses, and the opportunities which it thus affords of withdrawing the attention of the valetudinarian from his ailments.

Beyond the city extends on every side a country unequalled for the beauty of its scenery, as well as in the historic interest attaching to each spot. And within its limits nothing has been left undone by man to adapt to his tastes and pleasures the paradise which Nature has given him to inhabit. The most magnificent churches, extensive museums, numerous palaces, libraries, theatres, and gardens are all here collected together. "If Naples," says Forsyth, "be a paradise inhabited by devils, I am sure it is by merry devils. Even the lowest class enjoy every blessing that can make the animal happy—a delightful climate, high spirits, and a conscience that gives no pain. Their tatters are not misery, for the climate requires little covering; outdoor life is not misery to them that are born in it; and a few fingerings of maccaroni wind up the rattling machine for the day."

The influence of climate over the mind as well as the body is well illustrated here, for if it be true, as it doubtless is, that the gloomy and foggy atmosphere of London is impressed on the sombre and colourless faces of her citizens, it is no less certain that the clear, warm, invigorating air of Naples cannot be long inhaled without benefit by the "malade imaginaire."

It is no part of my intention, however, on this occasion, to expatiate further on the oft-recited beauties of this most charming of southern cities, or on its advantages as a winter climate in certain cases, which I have elsewhere fully described. My present object is merely to invite the attention of medical visitors very briefly to a couple of the less generally appreciated summer health resorts, or mineral waters that abound in the Neapolitan district. Of these spas the most celebrated is Castellamare, occupying the site of the ancient Stabiæ. The town is built along the seashore, and is sheltered by Monte St. Angelo from the east wind. Facing as it does the west, it thus enjoys a great amount of shade, and is protected from the excessive glare and heat of the mid-day sun, so distressing in summer on the opposite side of the bay.

The mineral waters of Castellamare enjoy a great reputation with Neapolitan physicians in the treatment of chronic gout and rheumatism. Four of these sources contain salts of iron, the principal of the chalybeate springs being the "Acqua Ferrata" rising in the Strada Cantieri. Four of the wells are saline, their chief ingredients being muriate and sulphate of soda, with chloride of calcium, and four are sulphurous and chalybeate, containing sulphate of iron, with a large volume of sulphuretted hydrogen gas. These springs, although so distinct in character, all rise within a small area at the base of the hill on which the town stands.

The physiological and therapeutic action of the Castellamare mineral waters are, as is indicated by the foregoing classification, necessarily very different. The ferruginous springs, especially the "Acqua Ferrata del Pozzillo," are very powerful chalybeates. The "Acqua Media" is a saline aperient not unlike Seidlitz water in taste. The action of the four sulphurous springs need not be here described, being similar in effect to other waters of the same class, and are used in the treatment of chronic skin disease and arthritic affections.

Off the opposite shore from Castellamare lies Ischia, the largest island in the bay of Naples, nearly twenty miles distant from the city and two miles from Procida. Recently this island has been rendered very accessible by the railway to Cumana, from the terminus of which at Torre-Gaveta steamers run daily to Ischia.

On every side this place presents the most unmistakable traces of the volcanic convulsions of which it has from time immemorial been frequently the scene, and by the last of which it was devastated eleven years ago. Through its whole circumference, moreover, the evidences of the same forces are apparent in the physical conformation of the island, which appears chiefly composed of trachytic and lavic rocks on the side of one mountain alone, viz., Monte Epomeo, twelve separate volcanic cones may still be traced. This mountain, which gives Ischia its peculiar pyramidal aspect, rises in the centre of the island, in successive series of highly-cultivated terraces, to a height of between two and three thousand feet.

As one of the most fashionable and coolest summer retreats from the intensifying heat and relaxing atmosphere of Naples in the dog days Ischia has at all times been much in vogue. But whilst still maintaining this reputation the island has, however, for some time past become comparatively deserted by the throng of health seekers who were formerly attracted to the hotels of Casamiccola and Lacco by the fame of the more than twenty different mineral springs—saline, sulphurous, and chalybeate—here in use, and many of which must now be spoken of in the past rather than to the present time. A very brief reference to some of the most celebrated of these sources, most of which were in the vicinity of the two towns just named, will suffice to conclude this article.

Within the last couple of years, however, Ischia has once more become known as a health resort but of a different class to that in which it was formerly included, inasmuch as aided by a subsidy of 40,000 lire offered by the Italian Government to the first hotel proprietor who rebuilt his establishment the newly reopened hotels Pithecusa and Piccola Sentenella are now unavailable. These hotels are frequented even more in the winter than during the summer season on account of the climatic advantage of the island which enjoyed a peculiarly mild and genial climate, although of a somewhat relaxing character, and hence is suitable as a winter sanitarium for some classes of invalids. As yet, however, its advantages in this way are hardly sufficiently established to require any further observation in these notes, which may be concluded by a very brief reference to some of the formerly popular mineral and thermal sources with which Ischia abounds, and sufficient accommodation for visitors to which may be obtained in either of the above mentioned hotels or in the re-opened hydropathic establishment.

The most important of the Ischia mineral waters are those of the vicinity of Casamicciola, a place which is now best known in England in connection with the two catastrophies by the last of which, in 1883, the town with the villages of Lacco and Foria and the neighbouring mineral springs were almost completely destroyed, and by which upwards of 2,000 visitors then perished, was charmingly situated on a rising ground near the sea, and at the time of my first visit contained one of the oldest and finest convalescent hospitals in Europe, viz., that founded in 1600 by the Montedella Misericordia, one of the religious institutions of Naples for patients discharged from the city hospitals.

Of the springs in this locality the principal one, viz., *Gurgitello*, rising at a temperature of 157°, in the Val Omberoso near Casamicciola and chiefly containing muriate of soda, with sulphates of soda and lime, and a large amount of carbonic gas was principally employed in baths in the treatment of chronic rheumatic arthritis, periostitis, and sciatica. The Acqua de Citara, near Foria, though having very similar chemical constituents but with a lower temp. (115°) than the Gurgitello, was mainly employed as a saline laxative and alterative internally, and once had a high reputation with Neapolitan practitioners in the treatment of chronic uterine hyperæmia and mammary and other glandular enlargements.

The Acqua d'Olmitello contains soluble salts of soda, lime, and magnesia, together with free carbonic acid gas, and is employed in renal and urinary disorders, cutaneous affections, and some hepatic diseases.

The Acqua di Cappone, as its name implies, resembles Wiesbaden water in its similarity of flavour to weak chicken broth. The temperature is 98° and it differs from the Gurgitello principally in strength. The chief use, however, as its ancient name "Acqua del Stomacho" implies, is in dyspepsia and chronic gastro-intestinal affections.

The "Acqua di Bagno Fresco," an alkaline water of the same character as the last described spring near which it rises, like Schlangenbad or Wildbad, and with as much truth, is said to possess the property of rendering the skin white and soft, being therefore especially favoured by patients of the fair sex, as well as in some cases of eczema and other chronic cutaneous diseases.

Besides these mineral and thermal sources Ischia also derived much celebrity from time immemorial from the therapeutic reputation of its natural vapour baths, or "Stufe" situated in the mound of lava near Lucco, which were heated by steam rising at a temperature of 130° through crevices into two small chambers in the mass of lava. These were chiefly employed in cases of chronic rheumatism, and rheumatic arthritis, strumous glandular enlargements, and some cutaneous affections of the same class.

◆

Selected Prescriptions and Therapeutic Notes.

80.—For Ozæna :—

℞ Ol. anisi, }
Creosoti, } āā ♏ xx ;
Vaselini ad. ℥j.

M.

Introduce into each nostril a small quantity of the application and inhale deeply while holding the other nostril.

La Semaine Médicale.

81.—An Eyewash in Cases of Purulent Ophthalmia :—

℞ Acidi boricis, ʒiss ;
Chlor. hydratis, ʒii ;
Acid. salicylatis, gr. xx ;
Lot. acid, carbolici, (1·100) ad ℥viij.

M.

At frequent intervals the eyes must be washed with the solution, and compresses soaked in it must be kept continually applied to the eyes.

82.—Guaiacol in Diabetes.—Dr. Clemens (Frankfort-on-Maine) has obtained excellent results in the treatment of cases of diabetes by means of guaiacol. Doses of from six to ten minims of the drug are administered three times a day in a tablespoonful of milk. Under this treatment, in the majority of cases, a progressive diminution in the glycosuria and polyuria takes place, sometimes even the sugar entirely disappears, and the general condition of the patients becomes greatly improved.—*La Semaine Médicale.*

83.—Glycerine of Creosote, to be used as a parasiticide :—

℞ Creosoti, ♏ iij ;
Glycerini, ad ℥j.

M.

84.—Embrocation for Sciatica :—

℞ Tinct. cantharidis, ʒss ;
Liq. ammoniæ fort. ʒiss ;
Ol. terebinthinæ, ℥ij ;
Ol. olivæ, ad ℥viij.

Ft. Lin. To be rubbed in twice daily.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, March 9th, 1894.

The President, Mr. J. W. Hulke, F.R.C.S., in the Chair.

Mr. C. Mansell Moullin related a case of a

BOY, ÆT. 14, CAME AS AN OUT-PATIENT TO THE LONDON HOSPITAL COMPLAINING OF INTENSE HEADACHE DUE TO A BLOW UPON THE RIGHT MASTOID REGION, SOME WEEKS BEFORE. AN ABCESS WAS FOUND AND OPENED (SUPERFICIAL TO THE PERIOSTEUM) WITH RELIEF.

A week later the boy returned with the same symptoms in an aggravated form, and was admitted. The abscess which had closed up was re-opened, and the periosteum incised, again with relief. Five days later the pain reappeared with drowsiness, restlessness, and other signs of cerebral pressure. The mastoid antrum was trephined and examined, but nothing was found inside it. It was not washed out as there was no disease of the ear. After this the boy appeared perfectly well for ten days ; then all the symptoms returned in an aggravated form with optic neuritis in addition on the right side. The skull was trephined over the temporo-sphenoidal lobe ; no pulsation was detected ; the dura was healthy, but bulged upwards, into the wound. A trocar and cannula were inserted in various directions without result. The bone was then removed from over the cerebellum and an exploration carried out there with equal want of success. Finally, a few drachms of fluid were drawn off from the descending corner of the lateral ventricle through the temporo-sphenoidal lobe and pulsation returned. Twenty-four hours after the patient died comatose. At the post-mortem there was no middle ear disease or inflammation upon the right side of the head or brain. In the left temporo-sphenoidal lobe was a very old encysted abscess, with some cohesions to the dura mater over it. Nothing else abnormal was found. Attention was directed to the fact that the abscess must have been latent for a very long time and suddenly roused into activity by the blow, and to the peculiar circumstances that the intense pain was three times relieved by a small operation upon the right side of the head when the real cause must have been the abscess on the left ; and it was pointed out that in future relief obtained by washing out a mastoid antrum cannot be regarded as evidence that the cause of the pain lies on that side of the head.

The **President** observed that abscess of the brain was not always associated with a rise of temperature.

Mr. **Arthur Barker** observed that patients' statements as to the absence of discharges from the ears ought not to be implicitly believed. He referred to the case of a man admitted on Monday last with symptoms of cerebral pressure. He had aspirated the brain and the cerebellum with negative results, but since then the symptoms had subsided, and the man so far appeared to be doing well.

Mr. **Clutton** pointed out that the trocar was not of much use in exploring for pus in the brain, and he mentioned a case in which careful exploration had failed to reveal pus, yet after death abscesses were found in the temporo-sphenoidal lobe and in the cerebellum.

Mr. **Moullin**, in reply, referred to a case in which he had explored without finding pus, yet three weeks later, after death, they had found an abscess occupying almost the whole of one cerebral hemisphere.

THREE CASES OF EXTRA-DURAL HÆMORRHAGE.

Mr. **Battle** read notes of three cases of extra-dural hæmorrhage which had been operated on by him during the past few months and they formed an interesting series. The first was the case of a woman, æt. 59, admitted to St. Thomas's Hospital with compound depressed fracture of the skull and compound comminuted fracture of the os calcis and astragalus. Temperature 95·4°. There was some oozing from the fracture of skull, but nothing to indicate the presence of the large clot of blood which was found at the operation, excepting the marked shock. No paralysis or even inequality of pupil. Operation was done for the depressed fracture. The clot found had compressed the right hemisphere to such an extent that no expansion followed the removal of the clot and she returned to bed with a large depression of the right side of the brain. The shock gradually passed off and no symptoms of unfavourable return developed. The leg was saved, although some sloughing of the wound followed, this was not accompanied by suppuration, and she left after a residence of 35 days. She is now able to walk, wearing a head and side iron. The second case was that of a boy, æt. 5, admitted to St. Thomas's Hospital and operated on two hours after his accident, a fall on the head from a coster's barrow. There had been no interval of consciousness. There was a baggy bloody swelling in the scalp extending from the temporal region upwards and backwards towards the longitudinal sinus marking the site of a simple fissured fracture of the skull. He was quite motionless and could not be roused, pupils equal and reacting to light. Then twitchings developed in the eyebrows, left ala nasi, left side of the mouth, afterwards in the left arm and leg. There was some twitching in the right side but less marked. The pulse was full and slow. At time of operation, pulse full and slow, right pupil the larger, but acting to light. No conjunctival reflex, no response on pricking with a pin. The diagnosis was fissured fracture of vault with extradural hæmorrhage. Operation was done by semilunar flap, insertion of blade of Hoffman's forceps in fissure, the edges of which were separated at head by 1-8th of an inch, removal of sufficient bone, and application of ligation of silk to wound vessel (anterior branch of the middle meningeal artery) by means of needle passed through the dura mater round it. The anterior end of the fracture ran forwards into the orbit. Recovery was perfect. In the third case the patient, a big strongly built man, was admitted to the Royal Free Hospital after a recent fall from a scaffold. There was a fissured and slightly depressed fracture in the right parietal region. No loss of consciousness. Drowsiness, unconsciousness, deepening into complete coma with left hemiplegia, and dilatation of the right pupil, a purple condition of the face, embarrassed respiration with much sweating developed. Immediately after the man was seen by Mr. Battle, operation was performed, and a large blood clot found over the right side of the cerebri. Much bleeding went on during the necessary manipulations. Bone was removed forwards and on failure to find the bleeding point the opening was extended backwards. There was an opening in a large vein of the dura mater ½ inch from the superior longitudinal sinus, near the posterior superior angle of the parietal. This was closed with a silk ligature passed by means of a curved needle. Another opening from the head from which venous blood flowed, no longer permitted escape after application of forceps. There was no expansion of the brain and the man died 4 hours later, not having recovered consciousness. The hæmorrhage in this case was very severe; and the bleeding point most difficult to find and secure; before death the temperature rose to 103·6°.

Mr. Croft observed that the great question was to know when to intervene and when to hold one's hand in the absence of symptoms pointing to pressure over the motor area, as in the author's first case. He referred to a case of his in pre-Listerian days in which he cut down and removed a large clot from a man's skull with success in spite of the absence of antiseptic precautions.

Mr. Kesteven supposed that psychical disturbances would equally indicate the necesssity for intervention.

Mr. Eve suggested that it might be possible to ascertain the circumstances under which the pupils in these cases were sometimes dilated on one or on both sides, and he hoped that means might be found to enable them to distinguish between hæmorrhages outside and within the dura mater.

Mr. Battle briefly replied.

A CASE OF EXCISION OF A PART OF A DISLOCATED INTERNAL SEMILUNAR FIBRO-CARTILAGE OF THE KNEE, WITH AN ACCOUNT OF THE RESULT TWENTY-ONE MONTHS AFTERWARDS.

Mr. Lockwood said that although a fair number of cases of dislocated semilunar fibro-cartilage had been operated upon, there was need of information as to their results. A report upon cases which have been done was much needed. Information as to the result nearly two years after the operation was given in the present instance. The patient was an engineer by profession who injured the knee at football. Nothing could be felt, but the joint was apt to lock under circumstances which entailed danger to the patient's life. Pain was felt on pressure over the internal semilunar fibro-cartilage, which also seemed too movable, and had probably been injured. The joint was opened by a vertical incision and the anterior third of the internal semilunar fibro-cartilage was found to have been torn from all its tibial attachments. It was removed and the remainder was sewn down to the tibia. The operation was followed by a slight attack of synovitis, and the patient was up at the end of a fortnight; a month later he walked thirteen miles. Subsequently after football he had an attack of synovitis, but no locking; indeed, the joint has not, he said, locked since the operation, and is perfect for wrestling, running, swimming, or bicycling. He is afraid, however, to play tennis or football, because he fears a sudden twist. The case, therefore, ought not to be considered a perfect cure, although a cure must have occurred in some instance. Mr. Lockwood considers that as asepsis is easy in the case of the knee, that the operation is attended with a small risk and very little anxiety.

Mr. H. Allingham said he had opened the knee-joint 35 times, in 12 he had sutured the semilunar cartilage, in 13 he had removed it altogether. Only one of the cases went wrong and had a resulting stiff joint. Cases of rheumatic arthritis often derived benefit from opening the joint, even though nothing further was done.

Mr. Croft recalled that he had read a paper on this subject in 1888, in which he had recorded the first case of deliberate removal of the internal semilunar cartilage.

Mr. Mansell Moullin said he had sutured the cartilage twice, but in one case all the symptoms returned in six months. He had removed the cartilage five times. He wondered what use this cartilage was. According to Mr. Sutton, it was the rudimentary remains of diseased muscular attachments. When injured, therefore, it was best removed, for its removal did not seem to entail any inconvenience.

Mr. Bland Sutton urged that because a structure did not appear to be necessary that alone was not a sufficient justification for removing it.

Mr. Moullin pointed out that his remark applied only to the injured cartilage.

Mr. Lockwood, in reply, said that if only slightly detached it might safely be sutured to the tibia, but if much damaged it ought to be removed At the same time he would not like to remove it without unless injured.

Dr. Cayley and Mr. Bland Sutton on a case of

PERFORATION OF THE BOWEL IN TYPHOID FEVER TREATED BY WASHING OUT THE PERITONEAL CAVITY, AND EXCISING THE PERFORATION.

The patient, a young man, æt. 25, was seized with symptoms of perforation about the twenty-fourth day of what seemed to be a mild attack of typhoid fever. Previously there had been no diarrhœa or other symptoms of intestinal ulceration. There was sudden excruciating pain in the lower part of the abdomen, vomiting and collapse; his temperature fell to 97°, and his pulse became extremely small, there was great tenderness over the belly and there seemed to be signs of the presence of gas in the peritoneal cavity. The conditions appeared favourable for operative interference, though the fever had run rather a protracted course, the type had been mild, and before the perforation the patient's strength had been well maintained. From the absence throughout of diarrhœa or other intestinal symptoms, we might infer that the ulceration was slight in amount, and probably chiefly situated rather high up in the ileum, where it would be more easily accessible. I think I have observed that the lower down the ulcers, the more severe is the diarrhœa. It is usually most severe when the ulceration extends into the large intestine, next when it is chiefly about the ileo-cæcal valve, least when, as is sometimes the case, it is mainly in the higher part of the ileum. Though these ulcers are very liable to perforate. Moreover, as this was about the twenty-fourth day of illness, we might hope that the fever was drawing to its termination. Accordingly, five and a half hours after the accession of the symptoms, the collapse having passed off, Mr. Bland Sutton, who was assisted by Dr. Berkeley, opened the abdominal cavity by an incision, 8 cm. long, in the linea alba, between the umbilicus and symphysis; the rectovesical pouch was found full of a brown turbid fluid which had escaped from the bowel, and bubbles of gas were being given off. On withdrawing a coil of intestine from the pelvis, a perforation was found in the centre of an oval ulcer, the outline of which was plainly apparent through the intestinal wall. In the adjacent mesentery a large pink gland was visible, no other ulcers were seen. The ulcer was excised by an oval incision, and the cut edges of the mucous membrane were drawn into apposition by a continuous silk suture, and then the serous surfaces were brought together by eleven Lembert's sutures, the peritoneal cavity was freely irrigated with warm water, and the stitched portion of the gut was laid immediately under the wound in the abdominal wall which was then closed in the usual manner. The operation lasted nearly an hour, a considerable portion of which time was occupied in washing out the peritoneum. At the end of the operation, the patient was much collapsed, but gradually rallied and lived till the sixth day, but ultimately passed into a typhoid state, with great prostration and rambling delirium. Some leakage of gas took place, and consequently, the central stitch of the abdominal incision was removed to allow a free vent. He was at first fed by nutrient suppositories and enemata, but subsequently, took liquid food by the mouth, and had a craving for solid food. He suffered a good deal from hiccough. He passed urine and motions without difficulty, and the last two days had diarrhœa, which seemed to be one chief cause of the final fatal prostration. He suffered no pain, and there were no signs of peritonitis. Permission was obtained for a partial examination. The sutured section of bowel was adherent to the edges of the incision through the abdominal wall. Fluid could readily be made to gurgle through this portion of the gut by pressure on the intestine above without any leakage taking place. The escape of gas was due to the sloughing of a stitch exactly in the middle of the suture. The perforation was situated twelve inches above the ileo-cæcal valve. The shock of the prolonged operation no doubt diminished the patient's chances of rallying, and in any future attempt it would probably be better not to excise and suture the ulcer, but after washing out the peritoneal cavity to attach the perforated bowel to the abdominal incision, and leave a fistula which could be dealt with subsequently.

Mr. H. **Allingham** said he had once attempted this operation, but the gut broke down on being touched, so he brought the perforated gut to the abdominal wound, but the patient died.

Mr. **Eve** recalled that five cases recorded at the Congress of American Surgeons, and all had proved fatal.

Mr. **Battle** asked what was the mortality of perforation in typhoid if left to itself? Senn had collected seventeen cases, of which four were said to have recovered.

Mr. **Goodall** said this particular case was a favourable one for operation. In his last twelve post-mortems on typhoid perforations he was sure that no surgical measures would have had a chance of success.

Mr. **Bland Sutton** pointed out that the operation ought only to be attempted under very favourable circumstances and he hoped that surgeons would not operate under any other circumstances. If in this case he had adopted the plan of making a temporary artificial anus he thought the patient would have had a better chance of recovery. The proper time to operate was just when the patient had rallied from the collapse. The perforated intestine would generally be found in the pelvis, where he had found it in this case.

Dr. **Burney Yeo** pointed out that had the patient recovered there would probably have resulted stricture of the gut where sutured.

Dr. **Cayley** admitted that patients might sometimes recover after perforation, but this must be regarded as impossible when there was much extravasation.

The **President** announced that, as a consequence of the plethora of papers and the fact that the next meeting fell on Good Friday, which was a *dies non*, the Council had decided to hold a meeting on the 30th inst., of which due notice would be given in the journals.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, February 16th.

The President, Dr. **Scott**, in the Chair.

EXHIBITS.

Dr. C. B. **Ball** exhibited a fresh specimen of tubercular peritonitis.

Dr. E. H. **Bennett** showed a specimen of fracture of base of skull, which had been accompanied by the unusual symptoms of maniacal delirium.

Dr. E. H. **Bennett** exhibited a specimen of osseous union of a fracture of patella, associated with fracture of femur, and attributed the completeness of the osseous union to the presence of the latter lesion.

Dr. **Myles** asked did the two fractures occur simultaneously. He also alluded to Professor M'Ewen's theory, by which he explained the frequent want of osseous union in fractured patella. The atmospheric pressure was supposed to force the aponeurotic structures in front of the patella between the fragments.

Dr. **Bennett**, in reply, stated that he considered it quite possible, and even probable, that the two fractures occurred simultaneously. He considered that the explanation of frequent non-bony union was separation of the fragments. There was always plenty of fluid effused into the joint to lift up any aponeurotic structures which might have fallen in.

MEDIASTINAL TUMOUR (COLUMNAR-CELLED CANCER).

Dr. **Finny** exhibited a specimen of this rare variety of intra-thoracic tumour. It was taken from a man, æt. 65, who had complained of weakness and emaciation for two years, and for three months before death of hoarseness and cough, with a small quantity of muco-purulent sputum. On admission to Sir Patrick Dun's Hospital, the left vocal cord was partially paralysed without any tumour or inflammatory disease of the larynx: an enlarged gland was to be felt in the right and left supra-clavicular regions, and a comparatively dull note on percussion was present over the manubrium. Œdema of the right neck and arm, then of the left and thorax set in, while the lower half of the body and legs were unaffected. and general cyanosis of the face, with great varicosity of the surface of the chest, pointed to great obstruction of the superior cava. The œdema almost entirely disappeared during the last fortnight of the patient's life.

The diagnosis of mediastinal tumour was confirmed by the autopsy, which revealed a very large hard tumour filling the anterior mediastinum and extending back to the front and left side of the trachea. Its lower limit was the apex of the pericardium and its lateral the adjoining lungs, to which it was slightly adherent. Its structure was tunnelled by the arteries springing from the arch and by the ascending and transverse portions of the aorta without the involvement of these vessels in the growth, but the veins were compressed and the descending cava just above the opening of the v. azygos was narrowed so that a No. 12 catheter could just pass. The roots of the lungs, the trachea, and bronchi were all free of disease. The left pneumogastric nerve ran through the malignant growth, and was widened and flattened, but the recurrent laryngeal could not be dissected out of it, although its course past the tumour was readily demonstrated.

The microscopic examination of hardened and stained specimens made by Dr. Earl showed the nature of the growth to be columnar-celled cancer with a considerable amount of fibrous stroma. It was impossible to decide on its origin; the probability was that the thymus gland was its starting point. Dr. Finny referred to the rarity of this form of mediastinal tumour, and to the greater frequency of lympho-sarcomata of which at first this case was supposed to be an example.

The section then adjourned.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, March 7th.

Dr. R. **Blair Cunynghame** in the Chair.

Patients.

Mr. **Cotterill** showed:—1. A patient from whom he had excised half the tongue for malignant disease with a very perfect result. The remaining half had so rotated in the mouth as to simulate a healthy organ.

2. An elderly man from whom he had excised part of the larynx also for malignant disease. He performed a preliminary tracheotomy, in which he used Trendelberg's tracheotomy tube, a form of tube which he said was of the greatest value in preventing even a drop of blood from reaching the lungs. The patient, who had the greatest part of one vocal cord left, could speak intelligibly, if somewhat indistinctly.

3. A young girl who developed an intussusception at the splenic flexure of the colon and in whom inflation with air or injection with water proved unavailing. He cut down in the middle line and very easily reduced the intussusception by pushing, not pulling, out the invaginated piece of bowel.

Dr. **Byrom Bramwell** showed two patients, one suffering from lupus, the other from ichthyosis, undergoing treatment with thyroid extract, who had already been shown to the Society. The result of the treatment had been very remarkable and satisfactory. In the ichthyosis case it was a noteworthy fact that mental trouble in this patient had arrested the progress of the cure, and in fact for a day or two had made the condition very considerably worse.

THE MICROSCOPIC PATHOLOGICAL CHANGES IN THE BRAIN.

Dr. T. S. **Clouston** gave a long and interesting demonstration of the microscopic pathological changes found in the brain and its membranes in insanity. It was illustrated by a most excellent series of sections and microphotographs, partly made by himself and partly by his assistants, Drs. Middlemass and W. F. Robertson. Beginning with the cerebral membranes, he showed on the screen photographs, first their normal and then their abnormal appearances. He then illustrated the same with regard to the blood vessels, especially calling attention to the nuclei in their walls and the close connection with the so-called vascular process, or as he thought, processes of Deiter's cells. With regard to the large pyramidal cells, he showed specimens of the granular degenerations found in them in general paralysis and chronic alcoholism. Two of the most interesting plates depicted the one, the pyramidal cells of the cortex in a new-born infant, the other the same cells from the brain of an idiot from birth. The cells were strikingly similar in appearance, in both being small, of a nondescript shape, and with very few and badly developed processes. Very distinct representations of Deiter's cells become under pathological conditions spider and scavenger cells were shown, one specimen especially, stained by Golgi's method, showing the processes of two of these cells remarkably clearly, and what is more, indicating that there may be more than one vascular process from each cell. Dr. Clouston gave a short indication of what he thought might be the use of these cells and their processes, stating as a hypothesis that the vascular processes might serve as channels through which nutrient material elaborated from the blood in nuclei of the cells of the vessel walls was conveyed first to the spider cell and thence by its other processes to the lymph spaces round the nerve cells themselves. In conclusion a series of slides illustrating the various stages of general paralysis and of alcoholic paralysis were shown.

Dr. **Batty Tuke** proposed that a vote of thanks should be given to Dr. Clouston for the demonstration. He thought that neurologists now had a fair idea of the arrangement of the cells of the brain, and that now they must direct more attention to the connections between the cells.

Drs. **Leith** and **Gulland** also spoke.

◆

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, March 1st.

The President, Mr. **George Eastes**, in the Chair.

Dr. **Silk** read a paper on

THE USES AND MISUSES OF ANÆSTHETICS.

After alluding to the fact that it was in 1844 that Mr. Horace Wells first used nitrous oxide for producing anæsthesia, and that the introduction of ether and chloroform followed soon after, Dr. Silk said that he thought that in the present year and in the Harveian Society it was particularly appropriate that the names of Wells, Norton, and Simpson should be remembered. With regard to the uses of anæsthetics he thought that it would be universally conceded that these were (1) relief of pain; (2) diminution of shock; (3) that they had contributed more than anything else to the advances which had recently been made in the surgical art. With reference to their misuses, Dr. Silk considered that there were grounds for believing in the growing tendency to the formation of "a chloroform habit." That even if anæsthetics were not actually given too frequently, at anyrate they were often given without sufficient weight being attached to the risks incurred. That he could not agree with the conclusion arrived at at the end of 1889 by the so-called Hyderabad Commission that "chloroform anæsthesia is free from risk," but thought on the contrary, that as it was an unnatural process, more or less danger attached to all forms of anæsthesia, and that it amounted to a misuse to administer a more potent when a less powerful drug would suffice; he also drew attention to the fact that in the years 1888 and 1889 the total death-rate from anæsthetics in England was 33 and 38 respectively, the chloroform death-rate for each year being 32, whereas in the two following years the totals went up to 42 and 69, and the chloroform rate to 36 and 62. Dr. Silk thought too, that inattention, and overdoses were undoubted misuses, and dilatory induction and under anæsthetisation nearly as bad errors of mal-administration, and the existence of these troubles afforded a powerful argument in favour of the recognition of the systematic teaching of anæsthetics as a necessary part of the medical curriculum. He agreed with Mr. Christopher Heath in deprecating the "exaggerated slowness of modern surgery," but again disagreed with the so-called Hyderabad Commission in the pronouncement that "chloroform and shock were incompatibles." He thought on the contrary that shock was seldom completely abolished under any anæsthetic, or in any stage of necrosis, though much might be done to mitigate the evil by subjecting the patient to a careful preparatory *régime*, taking care not to underfeed him, and if necessary to give a nutrient enema just beforehand.

The **President** remarked that the several degrees of anæsthesia were accompanied by danger, and some anæsthetics notoriously more so than others. He arranged them in an ascending series thus:—(1) Local anæsthesia, including refrigeration by ice, chlor-ethyl, or ether spray, and cocaine; (2) nitrous oxide gas; (3) A.C.E. mixture; (4) ether; and (5) chloroform. He considered it a misuse to employ an anæsthetic of the more dangerous description where one less risky would suffice. Again, it was a misuse to produce a deeper degree of anæsthesia than was required for the operation on hand. And lastly, it was a misuse to continue the anæsthesia longer than was absolutely necessary.

Mr. T. R. **Atkinson** insisted on the importance of students receiving adequate instruction at the London hospitals in giving anæsthetics. Patients heard so much about the advantages of anæsthetics that general practitioners found that they insisted on being anæsthetised for very trifling operations, even when they could not pay for the services of an expert. He thought also that rest in bed for a day or two rendered the use of an anæsthetic much safer, when this was at all feasible.

Mr. **Rickard Lloyd** emphasised the increased safety obtained by an administrator using an anæsthetic and method with which he is familiar; the contrary was likely to lead to abuse and danger. Referring to "hospital régime" of preparation of patients, he drew attention to what he believed to be the fact, that the patients were all fed and prepared for operation as if to be operated on at the same time, although there might be a difference of several hours in their coming upon the table, and considered the preparation of the patient should be carried out for operation at an exact time if possible; this was of course of greater importance in some cases than others. He did not consider it necessary, as a rule, to keep up the administration during the dressing of a case, except when muscular relaxation was desirable, as after tenotomies, &c., when plaster cases had to be applied.

Dr. **Hewitt** said that Dr. Silk's most interesting paper admitted of much discussion. There were, however, two side issues of the subject which appeared to him to call for a few remarks. He referred to the question of surgical shock, during or after the use of anæsthetics, and to the proper preparation of a patient before anæsthesia was induced. As to the question of shock, he (Dr. Hewitt) had seen all grades of surgical shock during anæsthesia, and was by no means prepared to say that such conditions could be avoided by keeping the patient very profoundly anæsthetised; he had indeed met with numerous cases in which during operations upon exhausted and anæmic subjects a light anæsthesia seemed to him to be attended by less disturbance of the circulatory and respiratory functions than a moderately deep, or deep, anæsthesia. Coming to the second point, viz., the preparation of the patient for the administration, he fully agreed with Mr. Woodhouse Braine that it was a wrong practice to give patients any food by the stomach for at least several hours beforehand. He contended that there was less risk of depression from giving ether after a fast of five or six hours than from the subsequent nausea and vomiting, which might occur had food been taken three hours before. Moreover, if food were present in the stomach, the anæsthetist might have considerable difficulty in securing true anæsthesia. He had found in such cases that very large doses of the anæsthetic were often needed, that repeated swelling with temporarily suspended breathing was common, and that delay and difficulty arose which would certainly not have shown themselves had the stomach been empty. He fully admitted that with exhausted subjects this abstinence from food was undesirable, but even in these cases it was often possible to administer nourishment by the rectum, and so to avoid vomiting depression after the anæsthetic. With all the other points raised by Dr. Silk he fully concurred.

Dr. H. F. Lancaster, referring to the remarks of the last speaker, said we had sufficient facts to prove the risks of commencing an operation before the superficial reflexes were abolished, and that it should be a constant rule to anæsthetise the patient fully prior to any incision being made. He also thought that while more prolonged fasting beforehand was no disadvantage in etherisation, as had been said, it might be less favourable when chloroform was used and the patient exhausted.

Dr. Hazel said that he frequently gave chloroform to his patients during labour, and he never saw any ill effects from its administration. It was his experience that women were less able to bear the pains of labour now than formerly, and therefore required the use of an anæsthetic. He quite agreed with Dr. Boxall that this should not be given too early in labour. Deep anæsthesia was rarely necessary, as the expulsive efforts of the patient tended to interfere with the proper aeration of the blood, and thus induced a partial narcosis by the accumulation of carbonic acid in the blood. In cases where the os uteri was rigid, he generally gave 10 gr. doses of chloral every half hour for three doses, after which he found that but little chloroform is required to produce anæsthesia. He rarely used forceps without the administration of an anæsthetic.

Mr. G. Everitt Norton said he quite agreed with Dr. Silk in his remark that the long induction of anæsthesia was to be avoided. He had noticed when the patients took a long time to get under the influence of the anæsthetic they often caused some trouble during the operation by faintness. He considered five minutes the average time required for producing anæsthesia. With regard to the preparation of patients, he did not agree with too long fasting, especially when chloroform was to be used.

Dr. Robert Boxall remarked that the frequent use of anæsthetics might lead to chloroform habit, and quoted some cases in support of this view. He detailed the use of chloroform preferably to other anæsthetics in labour, especially when the head was passing over the perinæum. He substituted ether for chloroform in any operative measures which had to be undertaken during the course of labour.

In reply, Dr. Silk said that, from the point of view of safety he should be inclined to place the A.C.E. mixture rather before ether, but above chloroform itself. He quite agreed that overfeeding, especially with ether, was impolitic, and he thought that by the use of enemata this might be avoided without actually starving the patient. He strongly objected to the plan in vogue at the Dental hospitals of allowing the administration of nitrous oxide to be a source of pecuniary benefit to the institution. Dr. Atkinson's opinion as a general practitioner that systematic teaching in anæsthetics was really much wanted, was a most valuable confirmation of what Dr. Silk had for some years been insisting on, and he hoped that the time was not far distant when such teaching would be properly included in the curriculum. With regard to the use of chloroform in labour, Dr. Silk thought that there might be some truth in the theory that the immunity enjoyed by parturient women was partly due to the slight cardiac hypertrophy said to exist at that period. In the more serious operations of midwifery he would be inclined to treat such women as ordinary patients, and give them ether if possible. Dr. Silk did not agree with the administration of alcohol by the mouth immediately before the operation.

LIVERPOOL MEDICAL SOCIETY.

Meeting held Thursday, March 1st.

The President, Mr. Chauncy Puzey, in the chair.

CASES.

Myxœdema with Glycosuria, treated by Thyroid Extract.—Dr. Macfie Campbell related a case, remarking that when the patient first came under notice, her condition was deplorable, her waist measurement was 28 in., at hips 45 in., face swollen, hair almost gone, eyelashes absent, skin harsh and dry, breasts pendulous, abdomen scored with linea albicantes. She suffered from amenorrhœa, and was apathetic, stupid, and lazy, had no energy, would sit all day rather than get up for anything. Urine, sp. gr., evening 1032, no albumen, sugar abundant. Morning 1013, no sugar. She was treated with Codia jaborandi, pot. iod., &c., but without any favourable result. She was then put on Murray's thyroid extract, 20 three times a day. Her improvement was rapid and satisfactory as to the myxœdema (photographs were handed round showing the improved condition), but the glycosuria was but little affected.

Adenoma of Pharynx.—Mr. F. T. Paul related the case of the patient, a woman, æt. 42, who complained of a tumour the size of a hen's egg at the back of her throat on the left side. On examining the throat the tumour was seen to project into the pharynx from the left side, and was covered with smooth mucous membrane, in which the veins were enlarged. It had a firm elastic feel, and moved on the subjacent structures. It was distinctly not infiltrating in character, but rather conveyed to the touch the sensation that it was encapsuled and could be easily shelled out. The patient was placed under the influence of chloroform. A preliminary laryngotomy having been done, and the glottis plugged, a vertical incision was made over the tumour through the mucous membrane, and the latter was loosened over its surface with the finger and a blunt dissector, and after some little difficulty the whole capsule was dissected out, and a smooth-walled cavity left behind free from every trace of the tumour. The hæmorrhage was very little. She recovered rapidly. She wrote three months after operation stating her throat is as well as ever it was.

Laparotomy for Intestinal Obstruction.—Mr. Paul also related a case in which the obstruction was due to kinking of the bowels owing to localised peritonitis, which was probably in the neighbourhood of the cæcum, but whether due to appendicitis or some other cause there was nothing to show. Mr. Paul opened the abdomen through a small incision in the middle line below the umbilicus, a distended coil of intestine was withdrawn and a small-sized intestinal drainage tube inserted. The coil soon collapsed but unfortunately did not relieve any others. It was kinked at both ends. Another coil was then tapped and a tube inserted, this proved to be a more lucky hit and at once relieved the general distension. The tubes were fixed as shown (diagram was shown). The patient made a rapid recovery, being up and about in three weeks, the wound in the abdomen being quite healed.

Two Cases of Gastro-Enterostomy.—Mr. Mitchell-Banks related the cases of two patients, both of whom were well over fifty years of age, who were clearly the victims of pyloric cancer. The operation was the same in both cases. An oblique incision was made parallel to, and a little below, the left lowest rib cartilages. The gastro-colic omentum was bored through, and a large hole made in it, requiring the ligature of a few vessels. The jejunum was picked up without difficulty. The opening of the stomach and jejunum and the adaptation of decalcified bone plates was carried out after the method of Senn, with a slight modification in the bone plates. The first patient never rallied from the operation and died on the following day. The parts were found to be quite natural. The stomach and jejunum were in perfect apposition, and there had not been any leakage. The second patient did very well for about two days, after which a quiet sort of welling-up of greenish-brown fluid took place unaccompanied by any violent retching or straining. After this he slowly sank and died a week after the operation. The parts were shown. The wound was healthy and there was no sign of any peritonitis or leaking into the peritoneal cavity. The stomach and jejunum lay in perfect apposition, and the silk threads remained intact, but when they were cut it was found that no adhesive lymph had been thrown out, probably owing to the patient's extreme weakness. The bone plates had disappeared all but a small portion of one of them. Mr. Banks wished to emphasise the fact that even with operations conducted perfectly satisfactorily the human body can only resist a certain amount of shock, and this important point is too apt to be forgotten in performing those serious operations on the abdomen which are now every day attempted, and only submit to operation such cases as seem to have sufficient strength to hold out against the shock of operation.

Mr. Richard Williams related a case of "Double Optic Neuritis."

Dr. A Wiglesworth read a paper entitled

ISOLATION IN SCARLET FEVER UNNECESSARY AND INEXPEDIENT.

Referring to the administration of carbolic acid, which he had practised for some years, first as a specific and then as a prophylactic, he concluded that there was some special effect produced upon the unknown micro-organisms of scarlet fever, which rendered it much less virulent, and this view seemed to him to receive a measure of support from the fact that whenever a patient had taken a certain quantity of carbolic acid, a peculiar dark colour of the urine appeared, and that when this was produced the urine would remain free from the usual putrefactive changes for from a week to a month, and sometimes altogether, and if it occurred the usually highly offensive ammoniacal odour of putrid urine was almost absent. Having a scientific basis to work upon in the study of Flugge's work on "Micro-organisms," he decided to "abandon isolation altogether." The plan adopted was first to carbolise the patient with doses according to age, and at the same time to put all the uninfected members of the household on carbolic acid, and when the characteristic hue of the urine has become manifested in the urine the author introduced into the sick chamber the other children, allowing them free access to the invalid until desquamation is completed and the house disinfected. Dr. Wiglesworth also gave details of cases in support of this unusual procedure, and a number of extracts from Flugge's work. Attention was drawn to the action of carbolic acid as an "attenuator" and "bactericide" upon a given bacillus, and for this purpose the experiments upon the anthrax bacillus were referred. The auther concluded by saying that the more freely the contagium from a carbolised scarlet fever patient is diffused, the better it will be for the welfare of the community at large, and if this course is universally adopted, scarlet fever will, in time, be no more the dreaded zymotic it is at present, but it will be as lightly regarded by the public as chicken-pox, which he believed to be a permanently attenuated virus of small-pox.

Drs Carter, Robertson, Hope, A. Roberts, Archer, Drysdale, Dickinson, Bradshaw, and others took part in the discussion which followed, and considerable doubt was thrown on Dr. Wiglesworth's arguments and the inferences he drew from them. It was a very generally expressed opinion that the exposure of healthy children to the infection of scarlet fever, even though they were considered by Dr. Wiglesworth to be protected by carbolic acid, was dangerous and unwarrantablo.

France.

(From our own Correspondent.

Paris, March 11th.

Traction of the Tongue.

Recalling to life by traction of the tongue as practised by M. Laborde has been very successful in the hands of those who have tried the experiment, and numerous are now the examples of life being restored after all hope had been lost. I cite a few of the most recent cases as related by M. Delineau, a fervent disciple of the author of this method and of M. Laborde himself.

On the 9th of May (said M. Delineau) I was called in the middle of the night by a midwife to the bedside of one of her patients. "I called you (she said) to attend to Mrs. B., who has just been confined of a still-born child after 38 hours of labour. She is losing a great deal and the cord having broken I cannot remove the placenta." I immediately set about withdrawing it, and in a few minutes the patient was out of danger. After prescribing an appropriate treatment, I was about to leave, when I chanced to ask to see the child, which was wrapped up in a towel and put away in a corner. The infant had a very good appearance and weighed about 7 lbs. "He is dead," said the midwife. I rubbed him and tried artificial respiration, but to no use ." Unfortunately, added the grandmother, nothing more can be done now." The method recommended by Laborde came to my mind while contemplating the body, and seizing the tongue between the first finger and the thumb, covered with a handkerchief, I commenced the rhythmical tractions. The grandmother became very exasperated; she thought that I wanted to tear out the tongue, and thus committing a sacrilege on the corpse! Without heeding the old lady, I begged the midwife to make alternate pressure on the abdomen and the flanks, while I drew on the tongue. Ten minutes passed without result. Besides the midwife and the grandmother there were present, aunts, relatives, and neighbours, all crying out "Let the little angel rest in peace."

I was tired out and about to abandon my attempts when I thought I perceived a spasm of the abdomen and a certain resistance of the tongue. Soon the child began to hiccough, and a feeble cry was heard; in a few minutes more he began to breathe and cry out vigorously.

This resurrection astounded all present, and they became frightened, believing that I had supernatural power.

I was sent for in October last, by a *confrère*, to a lady in her confinement. On my arrival, he told me that his patient was in labour already 24 hours, that the waters had broken ten hours previously, but no progress had been made. I applied the forceps and brought out an asphyxiated child, pulseless, motionless, and exsanguine. Leaving the mother to the care of my *confrère*, I turned all my attention to the infant and commenced traction on the tongue. At the end of five minutes the child began to breathe heavily and to cry.

My last case occurred on the 20th December, when I was sent for in haste to a dentist in the neighbourhood. Arrived, I found a lady of about 30 years of age, apparently dying. She had come to the dentist to have a molar extracted, but being very apprehensive of pain, she insisted on the administration of cocaine. Two-fifths of a grain had been injected close to the tooth, but five minutes afterwards, just as the dentist was about to proceed to operate, the patient became suddenly pale and fainted off. When I saw her she had all the appearance of being dead, the pulse could not be felt, and the body was covered with a cold sweat. I placed her immediately on the ground, on her back, and forcing open her mouth, I seized with a Péan forceps the retracted tongue and drew it forward in a swaying motion, the dentist pressing at the same time on the base of the thorax. In five minutes the patient hiccoughed, and soon was out of danger.

M. Laborde, who had been invited by the Clinical Society to describe his own method, explained how he was led to employ it, not by chance, but by patient researches on the nervous centres, and in particular on the rachidian bulb, in which the essential phenomena of life exist. In the course of his experiments he was able to satisfy himself that reflex phenomena exist for a considerable time after *apparent death*; that is to say, after the great functions of the body had disappeared, but while the functional properties of the tissues still exist. These reflexes could be recovered if the organism were brought again into play. The last to disappear is the *respiratory reflex.* An every day example of this fact is furnished by the administration of chloroform, by which the body is rendered incapable of every reaction, and yet the breathing continues as well as the circulation. Several methods have been employed to recall to life—flagellation, electricity. artificial respiration, &c., but none of these are as powerful as traction of the tongue. Two extremely sensitive nerves supply the tongue: the glosso-pharyngeal (the base), the lingual (the point), while the superior laryngeal sends several filaments to the same organ. These nerves, taking their origin either directly or indirectly from the bulb, stimulate this latter respiratory centre when vigorously drawn upon, and the bulb stimulates in its turn the phrenic nerve which commands the diaphragm. Such is the mechanism of the Laborde method. As to the exact limit of the persistence of the bulbar reflex, M. Laborde was not prepared to define, but he knew of some very remarkable cases where the patient had been apparently dead an hour and a half, and had been restored. Perhaps one of the most interesting was that related by his *confrère*, Prof Coutenot, of Besançon.

M. Coutenot was giving a lecture on asphyxia to his students, and, as a young girl had just died from tubercular meningitis, the idea struck him to go to the corpse and give a practical lesson on traction of the tongue. What was his astonishment, as well as that of the assistants when, after a few minutes he saw the respiration returning, the heart beating, and the face becoming coloured! This phenomenon lasted three-quarters of an hour. Death really existed, but the reflex action of the bulb had not totally disappeared.

Another case not less remarkable was that told him by his friend, Dr. Coriton, of Paris. This gentleman was called one night in haste to a patient dying from tuberculous bronchitis. In going up the stairs he was told that the woman had just expired. Arrived at the bedside, he determined to try what traction of the tongue would do. To the great surprise of all present, he succeeded in calling her back to life, and the lady lived for three months afterwards.

"You can judge, gentlemen," said M. Laborde in concluding, "by these examples of the efficacy of the method. It can be followed as a *pis aller*, but with nearly always certainty of success. In any case, I counsel you not to be afraid to drag on the tongue and its root; it yields very easily on account of its elasticity, and when you begin to feel a *resistance*, it is a sign of returning to life. The method has been employed with success in death from capillary bronchitis, nervous asthma, croupal asphyxia, drowning, asphyxia, syncope from any cause, &c. One word more. When, after persistent efforts, you have failed to resuscitate the person, you may be confident that he is dead, for you have by that fact an indubitable proof of death."

◆

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 9th.

FREE SOCIETY OF SURGEONS.

At the Surgical Congress of last year, Hr. v. Bergmann showed a patient suffering from

Tuberous Adenoma of the Liver,

a tumour nearly allied to carcinoma histologically, but very different from it in its clinical course. The large, knobby forms of carcinoma of the liver were mostly of metastatic origin, and were therefore generally multiple, but rarely solitary. Tuberous adenoma was operable. The speaker had removed a large piece of the tumour in March last. The wound healed, the abdomen became soft, the margin of the liver could no longer be felt, and the patient was up to the present free from recurrence.

Hr. Rochs then showed a salivary calculus taken from a man, æt. 27, after which he related a case of

Fracture of the Pelvis.

The patient, a man, æt. 25, fell under his horse and sustained serious crushings. He was unable to rise, and had violent pains in the abdomen. On removal into hospital he was found to be suffering from shock with ashy countenance; the eyes fixed and lustreless; the pulse small. Retention of urine, violent straining. The whole region from the pubes to the umbilicus much swollen, a catheter introduced, passed into a large cavity from which a quantity of fluid blood escaped. The urethra was certainly extensively lacerated and bruised. On determining that the symphysis pubis was fractured, sectio alba was performed, under ether, with evacuation of large quantities of blood clot. The bladder was opened and a catheter *à demeure* left in. The bladder was then sutured and a tampon placed in position. The patient was then put to bed on a mattress between two bags of sand. The operation lasted about three hours and 100 grains of ether were used (?). On awakening from the anæsthetic the patient felt very well, but there was violent cough with copious expectoration. For two days the patient appeared well, and the appetite was good, then tracheal râles and death with symptoms of œdema of the lungs. Section: Swelling and redness of all the air passages. No cardiac changes. The abdominal cavity and kidneys full of blood. Both pubic bones and rami of the ischium fractured. The pelvis which was removed was broken into splinters. The speaker thought the ether had caused the bronchitis, and had acted deleteriously.

Hr. Sonnenburg also related a typical case of Malgaignes fracture of the pelvis and showed the specimen.

Hr. Lexer related a case of

Torsion of the Spermatic Cord.

A healthy youth of 16 came under treatment in December last. Three years ago he was attacked with swelling of the left half of the scrotum, which gradually increased, and then to a certain extent receded. Subsequently such swellings came on repeatedly, generally suddenly, often whilst at work, and then disappeared. Two weeks ago, however, whilst working, the swelling returned, with radiating pains, this time very troublesome, from their extent and degree. The left scrotal half formed a regular oval tumour the size of a fœtal head, and was plainly filled with fluid. On puncture bloody serum escaped. Operation, December 19th. After laying open the vaginal cavity and clearing out the contents, a bluish-black shiny structure resembling gangrenous intestine came into view, and hanging by a stalk. It was seen to be a testicle become gangrenous from torsion of the spermatic cord, on which castration was determined on and performed. Recovery. The torsion which followed abnormal movability of the testicle resulted in closure and thrombosis of the vessels. There was later descent of the testicle in the case under notice. Anomalies of position, certain movements of the body also gave rise to torsion, especially horizontal inversion of the testicle. Very probably the former swellings in the left half of the scrotum had arisen from obstruction which gave way later on.

Resorption of Bacteria into Recent Wounds.

Hr. Schimmelbusch said that at the last Surgical Congress he had reported on experiments he had made on animals in disinfecting wounds infected by disease germs. The results were surprisingly unfavourable as regarded such attempted disinfection. In spite of making use of the most powerful disinfecting material, no results could be obtained. In the search for protective material, he had performed amputation, especially the tails of mice, shortly after infection, and had satisfied himself that even such amputations performed a few minutes after infection inoculations gave no result. From his observations he drew the conclusion that the micro-organisms passed into the body juices with great rapidity, and penetrated beyond the root of the tail in a very short space of time. In Bramann's klinik Niessen found that anthrax spores were demonstrable in the lymph glands in them from 1½ to 3 hours after infection. The speaker had in later experiments attempted to ascertain in how short a time infective germs inoculated into wounds were found in the internal organs—liver, lungs, spleen, and kidneys. These experiments were carried out last summer. He had wounded mice at the root of the tail or on the back, had infected them with anthrax, and after a certain time had killed them. The minced organs were then either placed on a platter or implanted into healthy mice. After he had obtained practical evidence from three to five hours after infection he shortened the time of infection gradually, and found that in a large number of cases virulent anthrax bacteria could be demonstrated in the organs. The question now arose, Did this happen in the pathogenic organisms only, or was it also the case with the saprophytes? In the case of rabbits killed five minutes after infection, he found after many experiments that numerous saprophytes were already present in the organs. As regarded plate cultivation, he remarked that it was necessary to take the whole or the greater part of the organs. Proofs of the presence of micro-organisms in the organs were never obtained when a few drops only were taken. To make proof certain it was necessary that the whole of the organs should be finely minced. At the first moment, the fact that such bacteria should be found within internal organs within such a short space of time appeared strange, but this fact alone gave an answer to the observation that amputation of the tails of mice a few minutes after infection was no longer of use.

It was known that fatty emboli containing cinnabar did not take five minutes to reach the heart from the marrow of bones. Resorption was naturally varied, according to the quality of the germs. In the case of the excitants of sepsis, the animal was already lost even a few minutes after infection, and not to be saved by local treatment.

Hr. Pfuhl was able from his own experiments to confirm the statements of the previous speaker. When wounds were from 24 to 48 hours old, however, the animal was in many cases not infected at all when germs were scattered over them. This fact was deserving of consideration.

Hr. Schimmelbusch said he had paid a good deal of attention to old wounds, especially burns. Poisonous material was not readily absorbed from the superficies or from fascia. The receptivity also disappeared quickly from other wounds, probably in consequence of the formation of products of coagulation, which afforded protection. Burns also were not readily infected. He had never succeeded in infecting a cauterised wound.

As regarded the disinfection of catgut, he said that in v. Bergmann's klinik it was disinfected in a 1 per cent. solution of sublimate, and that this solution rendered the disinfection perfect in one second, whilst hot air at 140 C. had no effect in two hours.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 9th.

Rhinoplastic Operation.

Hacker showed a woman at the "Gesellschaft" on whom he had performed rhinoplastic operation with apparent success. Two years ago he removed an epithelial carcinoma from the nose that left her quite disfigured. The tissue was taken from the forehead and along with the periosteum a centimetre square of bone was removed along with it.

Plastic Union of Ureters.

Budinger showed a preparation taken from a dog where he had obtained union of the ureters with the bladder analogous to Witzel's method. The ureters had been cut and applied to a new opening made in another part of the bladder where after several weeks they were found perfectly united and with a further operation they were made to discharge at a slight angle into the bladder. This operation was considered important in the future of human surgery.

A Chrondroma of the Chest Wall.

Schnitzler showed a man from whom he had removed a chrondroma two months ago. It extended from the mammillary line on the left side to the middle of the sternum and five centimetres upwards, having existed two and a half years. It was found at the operation that the tumour had extended through the intercostal space into the pericardium, a part of which had to be removed. The opening in the pericardium could not be closed, which necessitated the covering of the wound with a celluloid plate. In spite of the man's advanced years the opening where resection of the rib was performed is now almost closed from bone growth.

Ostitis Deformans.

Dr. Ewald brought a woman, æt. 49, who seven years ago had a fall on her elbow which caused great pain; five months later shivering and fever, the arm became red and swollen, and the bone thickened. After a recent injury a tumour formed on the manubrium sterni with pain, which subsequently went black. Another was to the head which caused pain with redness in the face, vomiting and other cerebral symptoms with neuritis optica. Anti-syphilitic treatment had no effect, but ergot injections greatly diminished the morbid condition. After the pain in neuritis had disappeared hyperostosis in arm remained, which resembling an abscess was cut into and found to be a spongy condition of bone. He thought the symptoms did not agree with ostitis deformans, conchiolin ostitis, but believed it to have a closer relationship to Gruber's leontiasis ossea. Prof. Paltauf thought that the case was a well marked condition of ostitis deformans. That no hyperostitis was found on the skull did not exclude it from this category as the invasion of fever was pretty well marked. He thought ostitis deformans was frequently overlooked till accidentally discovered in the post-mortem room.

Aortic Insufficiency.

Prof. Basch read a critical paper on the morbid changes of aortic insufficiency and its effects on cardiac pressure. In experiments with dogs it has been clearly shown that the blood pressure in the heart may remain the same, rise or fall. The last condition is easily explained by the diastole, where a part of the blood returns from the vessels towards the heart. Blood pressure in normal conditions may become very low without endangering life. He considers this condition of little clinical value. Ludwig found that dilating the heart with a tube the blood pressure in the left auricle fell; with a fall of pressure in the arteries it was found co-existing in the veins. As a result of his investigations Basch gave the following types of blood changes:—

1. Low pressure in the aorta was combined with low pressure in the left auricle.
2. High pressure in the aorta was associated with high pressure in the left auricle; hypertrophy of the left ventricle and dyspnœa.
3. High pressure in the aorta with low pressure in the left auricle; had hypertrophy of the left ventricle.
4. Low pressure of the aorta with high pressure of the left auricle had dyspnœa.

The Operating Theatres.

KING'S COLLEGE HOSPITAL.

Amputation at the Shoulder-joint.—Mr. **Rose** amputated at the left shoulder-joint in the case of a man, æt. 45. Some two years previously the patient was driving in a dog-cart in a severe thunder-storm. A flash of lightning frightened the horse, and the man distinctly felt a powerful electric shock passing up the left arm whilst holding the reins, after which he was thrown out and rendered insensible. The whole of the left upper extremity became gradually paralysed, and, although he experienced constant and agonising pain down the arm, yet the superficial sensibility of the hand was so diminished, that he had no sensation when accidentally burnt with a match. Twelve months ago the patient was admitted under Dr. Ferrier, and at the latter's suggestion, Mr. Rose cut down on the brachial plexus and stretched each cord, pulling forcibly both upwards and downwards. The result of this proceeding was not satisfactory; the pain increased to such an extent that the patient returned to the hospital requesting to have the limb removed. Inasmuch as the limb was completely and hopelessly paralysed, it was decided after consultation to perform amputation at the shoulder-joint, and at the same time dissect out the cords of the brachial plexus as high up in the neck as possible. The operation was performed by oval skin flaps, cut from without and inwards, according to Larrey's method. The cords of the brachial plexus were traced up under the clavicle, and dissected out as thoroughly as possible through a vertical incision in the posterior triangle of the neck. This proved to be a very difficult proceeding in consequence of the parts having become matted together by the previous operation. Mr. Rose remarked that if the pain returned, the only treatment left would be the performance of laminectomy so as to divide all the posterior roots of the plexus. It is satisfactory to state that since the operation the patient, although at first not entirely free from some slight pain, is daily improving.

MIDDLESEX HOSPITAL.

Osseo-chondro Sarcoma fixed to both Bones of the Leg—Stephen Smith's Amputation.—Mr. **Pearce Gould** amputated the right leg of a young man, æt. 17. The operation was performed on account of an osseo-chondro sarcomatous tumour which had first been noticed about fourteen or fifteen months ago; the tumour was sessile, hard and nodular, rapidly growing, and seemed fixed to both bones, and to occupy a kind of sulcus in the fibula; the circumference of the affected limb was two and three-quarter inches more than that of the other; it gave rise to no pain except on motion. Mr. Gould thought the only thing to be done in such a case was to remove the limb, as, were it left, secondary deposits in the internal organs would in all probability take place. A tourniquet having been applied to the femoral, the limb was amputated at the knee-joint by Stephen Smith's method. The operator remarked that in this operation the joint is hardly opened, very little being exposed, as the condyles are covered by the semilunar cartilages; another great advantage, he pointed out, was the very small section of the stump. Mr. Gould employs no ligatures, but uses torsion for all the vessels. After suturing the flaps the dressings were applied very firmly and tightly bandaged, the surgeon remarking that he hoped by pressure to bring the flaps together perfectly and get union by first intention.

GENERAL HOSPITAL, NOTTINGHAM.

Opening Mastoid Cells.—Mr. **Owen Taylor** operated on a child who had been suffering for some time with great pain, and also with a considerable offensive discharge from the ear. Mr. Taylor cut down, and after raising the periosteum made an opening into the mastoid cells with a small gouge until it was possible to pass a probe backwards and forwards from the external meatus. He remarked that on some occasions he left in a drainage tube, but did not think it necessary in the present case.

Perinæal Section.—The same surgeon operated on a robust-looking young man who had been suffering for some time from stricture. It was absolutely impossible to introduce a catheter. A straight staff having been passed down to the stricture, Mr. Taylor cut down on its point in the perinæum, and managed after some difficulty to pass a probe along the urethera into the bladder; he then withdrew the probe and introduced a catheter through the perinæal wound into the bladder, and finally passed a catheter down the penis along the whole length of the urethra into the bladder. Mr. Taylor remarked on the unsatisfactory nature of these cases both to the patient and to the surgeon.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 14, 1894.

DUST DISEASES AND THEIR PREVENTION.

The relation of dust to pulmonary affections is a subject the investigation of which has already led to many valuable practical results, and which is still far from being exhausted. Dust of a non-irritating nature is necessarily inhaled into the lungs of town-dwellers, where it causes the dark and mottled aspect so familiar on the post-mortem table. The irritating dust, on the other hand, which is encountered in many occupations, leads to more or less serious pathological conditions of the pulmonary organs. Thus it may cause bronchitis, acute and chronic, emphysema, asthma, bronchiectasis, fibroid conditions, hypertrophy of bronchial glands, and phthisis, with a whole chain of attendant vascular disturbances. These dust diseases, or pneumokonioses, are met with, as everyone knows, among millers, masons, miners, grinders, and others who follow occupations which habitually expose them to a dusty atmosphere. This injury is, in the first place, mainly mechanical, and usually has a direct relation to the texture of the material which furnishes the dust. In this way steel particles are more deadly than stone, and the latter than flour. In other cases the injury to workmen is partly mechanical and partly chemical, as in the lead enamel grinding trade. So much for the evil, which is obvious enough, and needs little more than the above passing reference. A great deal more discussion is wanted, however, when we inquire as to what has been done in the way of prevention. The two great preventive measures are undoubtedly free ventilation and the introduction of wet processes. It is a well-known fact that the substitution of wet for dry grinding in Sheffield was followed by a great fall in the number of deaths from phthisis. A similar principle might be applied with advantage in other trades. For instance, the dust raised in grinding lead enamel is of a peculiarly deadly nature, since it acts both as a mechanical and a poisonous irritant. Lead enamel is practically insoluble, and there is no doubt that many of the steps in its manufacture could be carried out equally well by elutriation and other wet methods. Ventilation, again, is often defective in the enamel factories. The beneficial action of a free circulation of air is probably due to the dilution and the removal of noxious particles. Nowhere has the improvement of ventilation been followed by better results than amongst our mining population. To take a single instance, it has lately been officially reported that in the mining division of Cornwall the proportion of deaths from phthisis or "miner's disease" has of late years decreased. This satisfactory result appears to be due chiefly to the better underground ventilation, consequent on the introduction of boring machinery and of other improved conditions. Some years ago the whole question of miners' phthisis was closely investigated by the Royal Cornwall Polytechnic Society, who offered prizes for sound information, and obtained a quantity of valuable matter, which is to be found in their annual reports of that time. This public-spirited action affords an excellent illustration of the good that can be effected by local bodies, if they will only be content to confine their scientific ardour to subjects at their feet, so to speak, and within the grasp of an average comprehension. Conducted on such lines the work of provincial associations is likely to afford substantial help in arriving at precise facts and figures with regard to dangerous employments. They will be also in a position to acquire exact information as to methods, and to suggest improvements in trade processes. Their data would then be simply invaluable to the scientific man, in whose hands the application of preventive measures must ultimately be placed. When thoroughly sound conclusions have been arrived at it is the duty of legislators to frame laws in accordance with the facts submitted to them. It is a well-marked tendency of modern legislation to make compulsory all measures that have been shown to be clearly preventive. Bearing this in mind, one may safely assert that the compulsory legislation of the future will find a large and useful field, so far as the happiness of many members of the community is concerned, in the control of dust-producing occupations. Whatever may be done, it is unlikely that the whole of the mischief could be abolished in each particular trade. The risk, however, could and should be reduced to its minimum. The steady aim of the sanitarian in dealing with dust diseases will be levelled at the preventible margin, and he will not fail to make due allowance for the unavoidable residuum.

◆

THE PREVENTION OF PHTHISIS.

One of the most striking features of the age, thanks mainly to the printing press and the steam engine, is the rapidity with which new ideas are established. The theory that we see timidly and tentatively advanced to-day becomes the accepted doctrine and dogma of to-morrow. It will be of interest to the workers of fifty years hence to note what were our ideas in 1894, thirteen years after the discovery of Koch's bacillus, with regard to the prevention of phthisis. It is a curious fact that, in spite of all the attention that has been bestowed on the subject, the real nature of the disease has only within the last few years been brought into the scientific grasp. The unrivalled lectures of the late Professor Walshe, with all their wealth of systematic observation, may be taken as summing up the knowledge of the last generation upon phthisis. They were wonderfully accurate clinical studies, while as regards treatment they pointed to no more hopeful future than the relief of symptoms and the occasional cure of early cases. All that, however, is now changed, and consumption is singled out as one of the early conquests of preventive medicine. The possibility of such a result has been brought about by a number of causes, among which the following may be taken as the chief: First, the registration of deaths, a step that made it possible to study disease, so to speak, in mass. Secondly, the great experimental advance made about the year 1840, which proved that tubercle could be reproduced in animals by the inoculation of tuberculous material. Then came the crowning and classical discovery by Koch in 1881, which afforded logical proof that tubercle depends on the presence of a specific bacillus. So far it cannot be said that scientific medicine has arrived at any very valuable outcome in the way of direct curative treatment. Indeed, the most important result of modern researches appears to lie in the immense impetus that has been given to the study of prevention. The facts on which the sanitary reformers rely are now for the most part matters of common knowledge. For instance, it is well recognised that tubercle bacilli abound in the dust of rooms which have been inhabited by consumptives. That similar pathogenic organisms occur in the flesh and milk of infected animals, especially of cows. That the sputa of consumptives is scattered broadcast, and is probably a fertile source of infection, both of man and of the lower animals. Guided by these and a host of other considerations of a cognate nature, the attacks of health administrators have been directed against the micro-organisms as the *fons et origo mali.* Infected clothes and clothing have to be carefully sterilised, while ordinary handkerchiefs are replaced by pieces of paper, which are burnt after use. All sputum is destroyed, being first collected in spit-cups charged with some efficient antiseptic. And then, going further afield, the sanitary authorities advocate rigorous supervision of markets and dairies, with full powers to destroy infected animals or meat. The idea that consumption should be notified as an infectious disease has been before the sanitary world for some years. Certainly, if we admit that any class of disease should be notified, we cannot logically exclude so highly infectious a malady as tubercular phthisis. To many especially to those who have not fully grasped the significance of micro-organisms in disease, the proposal to disinfect any house that has been inhabited by a phthisical patient will appear little more than a startling and useless innovation. Nor will the kindred propositions of notification, isolation, and disinfection appear less absurd to the non-scientific, albeit qualified intellect. Stranger things, however, have come to pass than the realisation of these dreams of the sanitary reformers. For instance, preventive medicine has shown us how to prevent the cholera bacillus from taking hold of our communities. If that can be done in the case of cholera, why should it not be effected with consumption, especially now that science has furnished us with a definite object of attack in the shape of a specific micro-organism? The prevention of phthisis is well worthy the attention of political economists, for its ravages cause an enormous annual loss to the national wealth of the United Kingdom.

◆

THE STATUS OF ASYLUM MEDICAL OFFICERS.

"The career of the majority of assistant medical officers in asylums is one of the saddest pictures our profession affords." Thus writes an asylum medical officer who should know something of the subject of which he is speaking. The grievances of which these officers complain appear to be many and various, and so far as we have been able to inquire into the matter, the grounds for their dissatisfaction are incontrovertible. In the first place, no understanding ever seems to have been arrived at defining their precise professional status. For the most part the appointments would appear to be regarded as belonging to the same category as that of house physicians. But, as has been pointed out, it is quite a mistake to make any such assumption. The duties and responsibilities of the assistant medical staff in the large county asylums are totally different in their scope and purpose from those generally associated with the post of a house physician. The latter appointments at hospitals are held by young qualified medical men, who, acting directly under the visiting staff, are eager to take advantage of a subordinate position of the kind for the purpose of gaining experience. Usually it is the case that it is by this means that they make their first step in the practical exercise of their newly-acquired knowledge. From the beginning, moreover, they never lose sight of the fact that such an appointment can only be one of a temporary description. The question of permanency never enters their heads, and, obviously so, among other reasons, in consequence of the fact that the posts are entirely subordinate ones, and, beyond a certain occupancy, are not helpful in promoting the advancement of those who hold them. With regard, however, to the posts of assistant medical officer at an asylum the matter is entirely different. The young medical men who fill them have in most cases previously held junior or resident appointments at one or more hospitals elsewhere; they may, or may not, have had experience in the treatment of the insane, but it may be assumed that after the first few years of their work in an asylum they will have fully made themselves competent officers. After this has been the case then their hardships begin. Naturally in devoting their whole time and energies to a specialty of the nature of insanity, they do so with the view of making their livelihood out of it. But what is in store for them so far as promotion is concerned? Experience shows that they have but little to expect. Their position has thus been described by one who is well qualified to speak: "There is a superintendency for only a very small proportion of assistants, and the men who do not reach the coveted goal find, when it is too late, that they have spent the best years of their life in a service that is not a service, as are the Army, Navy and Colonial Services, and that unless they rise to the highest point all they can hope for is at the very best £300 or £400 a year, a very subordinate position, inability to marry, absence of home or independence, and a much inferior position to that which even this small income would command in general practice." This picture is the very reverse of attractive, and, in truth, it reveals so melancholy a state of affairs that it would not be surprising to find young medical men of the future severely leaving these asylum appointments alone. "The outlook," says a writer and an assistant medical officer of fourteen years' experience, "is black indeed; vacancies are few, and chances of promotion almost *nil*, added to which there is a tendency to limit the term of appointment, and to cut down the already inadequate salaries." If this be the true state of affairs, and there is no reason for supposing that it has been exaggerated, we have no hesitation in stating that the asylum authorities who are responsible for this policy will find that they are making a very grave mistake. There can be no question that for the well-being of a large asylum there must be two or more permanent officers in addition to the superintendent. How is it to be supposed that an institution of the kind with a community of 1,000 or more persons could be efficiently worked with a staff of medical officers changing at intervals? The principle must be admitted that permanent posts are a *sine quâ non*, and if, as we maintain, permanency must be regarded as an essential feature in the appointments, then means should be taken to render them worthy of being filled by competent men and such as competent men would feel themselves justified in filling. The serious aspect of the condition of affairs portrayed in the above quotations is that it is impossible to look for much original work or advancement in the specialty of insanity when those from whom enlightenment should come are hampered and harassed by surroundings the least calculated to encourage them in their work. There can be no question that the almost continual restraint and seclusion, and frequent lack of consideration both for social and professional position, do tend to diminish interest and abolish energy and enthusiasm among assistant medical officers.

◆

Notes on Current Topics.

The Closing of a VI. Century Well.

The concerns of this prosaic and matter-of-fact world are largely regulated by the spirit of commercialism which naturally everywhere abounds. The purveyors of faith-curing "bubbles" simply continue their business as long as it continues to "pay." Of course the "bubbles" are not burst by those who promote them, for such a course would be entirely opposed to all commercial enterprise. But the end of the curing schemes usually comes from persons who "find them out," that is to say, the public is now too much informed to be imposed upon for long without learning that they are being duped. The faith-curing business, sad to relate, has still its votaries, and the world still contains a large number of persons who lay themselves out to disgorge the contents of their purses for the benefits of scheming individuals. But, these reflections apart, a curious if not interesting example of the progress of the times, and the decline of sentiment where the latter receives no support commercially, has just occurred in a place called Towyn, Merionethshire. A celebrated well exists in the locality known as St. Cadvan's Well, in which it is stated that Giraldus Cambrensis, the historian, and the then Archbishop of Canterbury, bathed, when on their pilgrimage through the Principality in 1180. The attraction of its waters throughout the many centuries has been its reputed healing properties, and its usefulness in rheumatism, dyspepsia, and other maladies. But the proprietors of the well are now reported to have made an end of it; the other day they actually proceeded to the expedient of filling it up with stones! This course was decided on in consequence of the fact that the well no longer "pays"—the public no longer crowd to it to be cured—and the reigning spirit of commercialism has led to the conversion of the time-honoured buildings surrounding the well into those of a coach-house and stables. The deed having now been perpetrated, the townspeople are naturally incensed that the memory of their patron saint should have thus been dishonoured. But, surely, it must have been in their power to have made an offer to the proprietors for the preservation of this interesting relic of early years. Public subscriptions have frequently been started for similar purposes, and how is it that the townspeople of Towyn have not availed themselves of this plan?

A Midwife's Action for Damages against a Medical Man.

Perhaps Mr. Holmes, a practitioner at Gorton, might have used a little more discretion in his remarks respecting the services of a midwife who sued him last week for damages for libel. But we do not gather from the report that anything more was said than what the circumstances of the case seemed to warrant. Briefly, the case was as follows: Mr. Holmes was summoned to a woman whom he found to be suffering from all the symptoms of puerperal septicæmia; the patient in her confinement had been attended by the midwife in question, and at the death of the woman, the practitioner wrote to the registrar for births and deaths a note to the effect that the deceased had come by her death by the shameful neglect of the midwife who confined her, and that if nothing else could be done, it was essential to prevent the midwife from carrying the infection further. At the coroner's inquest which followed, remarks to the same effect were made by the practitioner in question. Hence the proceedings for libel. The midwife stated at the trial that, while she averaged 242 cases a year, since the inquest she had been called in only three times. After hearing the evidence on both sides, Mr. Justice Day characterised the case as a very serious one, and in the end the jury brought in a verdict for the plaintiff for £80, with costs. In some respects the trial has been an unsatisfactory one. Judging from the report before us, the whole case for the defence rested upon the connection between the development of the puerperal fever and the presence of the midwife. If the midwife was directly responsible for the onset of the fever, either by conveyance of infection or by direct neglect, then the strictures of the medical man were justified. But evidence upon this point seemed to be wanting, and in its absence the jury naturally could come to no other conclusion than that the libel had been proved. Before any such case could be successfully defended, the defendant would have to clearly prove that the plaintiff was "wilfully" neglectful, a matter upon which it would be by no means easy to convince a jury.

Infant Mortality at Cardiff.

At a recent meeting of the Cardiff Burial Board, the Mayor of the town drew attention to the fact that, out of the two hundred interments for last month, more than half were those of children under the age of five years, and he was of opinion that if such were the case with animals, a Government inquiry would take place. He further stated that he knew of a house in the district where all the children had died within a week during last month. The committee were apparently not much disposed to regard this as anything very abnormal, and it was only reluctantly that they agreed to refer the matter to the medical officer of health. It appears that the subject had on former occasions come forward for discussion by the Board, with the result that the medical officer of health, on being communicated with, replied to the effect that there was no special cause for alarm. Clearly, however, the time has arrived when a full and exhaustive report should now be prepared by this officer, with a view to ascertaining the true facts of the case. Meanwhile, the Mayor of Cardiff is to be congratulated upon his public-spirited policy of insisting upon the matter being thoroughly inquired into.

The Medical Officer of Health for Oldham.

The important district of Oldham, of which Dr. Niven, before his migration to Manchester, held the post of Medical Officer of Health, has not been left long without the appointment of a suitable successor. The Sanitary Committee of the district met the other evening, and out of seven applicants for the vacancy, recommended the candidature of Mr. C. H. Tattershall the present Medical Officer of Health at Eccles. Mr. Tattershall, besides holding office for five years at the latter place, has had also experience as Deputy Medical Officer for Salford. His claims were strongly urged upon the Committee by the leading members of the profession in the district, and in succeeding to the post vacated by Dr. Niven, Mr. Tattershall, who is just over thirty, is greatly to be congratulated.

Death from Chloroform.

While chloroform was being administered to a woman last week in the hospital at Coventry she became very violent, and then the heart suddenly ceased to beat. Everything was done to restore life, but all to no purpose. The anæsthetic was given for the purpose of the removal of a nasal polypus. The assistant house-surgeon, who was the administrator, was acquitted of all blame in the matter by the jury who were summoned to inquire into the cause of death.

Clearance of a Condemned Area in Sheffield.

There is a movement on foot on the part of the Sheffield Corporation to clear out a certain area situated in the oldest portion of the city, which is in a most unsanitary condition. The proposed action on the part of the Corporation is certainly not premature. Back-to-back houses, narrow streets, faulty and defective drainage, middens in close proximity to the houses, in fact, every canon of the laws of health set at defiance, makes one wonder such a state of affairs could have been so long tolerated by the authorities of the city. The condemned area extends over 25,501 square yards. It has a population of 278 to the acre. The death-rate in the city generally is 22 per 1,000; in the condemned area the death-rate was 31 per 1,000. The cost of the scheme the Corporation has in view is estimated at £59,672 exclusive of the cost of rebuilding. Major-General H. D. Crozier, R.E., held an inquiry into the matter on Wednesday, February 28th, on behalf of the Local Government Board, and inspected the condition of the places involved; it is said that he has formed a pretty strong opinion as to their condition. In the event of a scheme to construct a new central station in Sheffield being carried out as at present in the process of promotion, the condemned area will be the site selected. This would, in every way, be an advantage to the city of Sheffield.

A Funny Decision.

The Woman's Charity Club of Boston has decided by 43 votes to 38 to forbid all medical students the privileges of clinical instruction at operations performed in the hospital of the Club. This decision has apparently arisen out of the mistaken notion that gynæcological operations must always be a source of attraction to students. But even if such should be the case—what then? Women to the end of time will have to be operated upon gynæcologically—unless, indeed, Nature steps in and forgets to put their appendages and uterus in when the embryotic parcel is being made up. If this were the case, however, there would be no need for woman's hospitals, and the hospital of the Woman's Charity Club at Boston would have no reason for excluding students. With the dawn of the twentieth century in view, the decision arrived at by this Charity Club is certainly a remarkable one. But, perhaps, the Boston women are different to those in other parts of the American Republic.

Small-pox Delirium.

From time to time cases are reported where small-pox patients have escaped from hospitals in a delirious state, and have done themselves serious or even fatal injury. As most people know, the delirium of small-pox is of a peculiar type, and persons affected with it will climb up chimneys, leap through windows, and scale walls in their blind efforts at escape into the unknown. It behoves the authorities of such institutions, therefore, to be ceaselessly on the alert in order to prevent such untoward occurrences. Indeed, it may be said that they should be quite as careful in this respect as those who are responsible for lunatic asylums, inasmuch as a small-pox patient can hardly run loose, for however short a period, without scattering the germs of his disease broadcast. The occurrence of such an event as the escape of a delirious patient is a reproach to those in charge of the hospital, for they of all people should be alive to the circumstances of the situation. The danger to the wandering patient has been lately illustrated with tragic emphasis in Birmingham, where an inmate escaped from the small-pox hospital and was drowned in the canal which runs close by. The nurse was positive at the inquest that she had left the patient for ten minutes only. That period of time, let it be remarked, would be enough for an insane patient to murder half a dozen people, to set the ward on fire, and to get away to a less restrained field of action. Another point raised at the inquest, and not answered satisfactorily, was whether a certain door communicating between the hospital grounds and the canal had been left open or not. The moral of this case is obvious, and unfortunately it has been enforced in a similar disastrous way over and over again. The managers of fever hospitals will do well to lay these lessons to heart, or some day they may be startled by actions for culpable neglect on the part of bereaved relatives. The medical officer of the hospital said he gave clear instructions that the deceased was not to be left alone. Deceased was in a cottage by herself, and the nurse stated in her evidence that she was in charge of two other wards in addition to the cottage.

The Secretaryship of the Royal College of Surgeons, Ireland.

On Thursday last the President and Council of the College received and accepted with regret the resignation of Dr. Jacob of his position as Secretary of the Council, which he has held since the year 1884. They also voted to him a continuance of his salary until the termination of his year of office, the first week in June. Dr. Jacob succeeded his father, Dr. Arthur Jacob, as a Member of the Council of the College in the year 1869, and served in that capacity for fourteen successive years with the exception of a portion of one year. On the death of Dr. James Stannus Hughes in the year 1884, Dr. Jacob was elected Secretary, and has since been unanimously re-elected in each June for ten years. Meanwhile, the secretarial functions had so greatly increased by reason of the development of the Conjoint Examination system, and under the Medical Act of 1886, to which the Council of the College has been obliged to devote almost continuous attention for several years, and the work of administration of the amalgamated schools now merged in the School of the College has required such constant attention by the Council that, although the President and Council recognised the increased duties by increased salary, Dr. Jacob did not feel able, having regard to other avocations, to seek to retain the office. The Council has ordered that the election of a Secretary of the Council shall be proceeded with at its meeting on the 5th of April. No candidate is admissible, under the bye-laws, save a Fellow of the College. No salary is as yet finally fixed, but it is suggested that a saving of the collegiate finances shall be effected by reducing the salary to £150 or £100 a year. Dr. Jacob has also resigned the Secretaryship of the Committee of Management of the Examinations held by the College and the Apothecaries' Hall of Ireland.

The Mortality Statistics at the Chelsea Hospital for Women.

The Medical Staff of the Chelsea Hospital for Women have just presented a voluminous report to the Board of Management of the Institution containing all the details of the operations performed by them during the past year, together with a full record of the mortality arising therefrom. A copy of this report has been forwarded to us, the comprehensiveness of which reflects the greatest credit upon the compilers. It could only have been compiled at infinite pains and trouble, and is in itself a sufficient proof that the fullest inquiry is courted by those connected with the institution at the present juncture. It will be remembered that of the 36 deaths out of a total number of 636 in-patients a large proportion was attributed by the Medical Officer of Health to septicæmia after operation. The answer in the report to this allegation is: "We find that in 13 of the total 36 cases no operation had been performed; that 14 deaths were due to sepsis, but of this number 6 were infected before admission to the hospital, and doubtless excited a malign influence upon our other operations. As much may be said of 8 of those cases out of the 13 which were never operated on. . . . Nine deaths after operation were due to causes other than sepsis. Moreover, among the cases which have been admitted during the past year, which have materially added to our death-rate, are one case of bronchitis, one of broncho-pneumonia, one of suppurating kidney, and one of approaching child-birth, resulting in the death of the child, all of which told against our death-rate." The report also points out that the analysis of the cases reveals that very few, if any, of the deaths in the past year were due to sanitary defects in the construction of the hospital. But apart from the questions at issue, much interesting information is contained in the analysis of the cases of which the report is mainly composed, and for this reason the compilation may be profitably perused. We would also draw attention to the letter in another column of our present issue, which will be read with interest at the present juncture.

The Dublin Students' Organisation.

The students have submitted to the Council of the College of Surgeons a memorial signed with 315 names, which sets forth the subjects of their present complaints, and the matter will, no doubt, come under consideration at the meeting of the Council next Thursday. The points made by the students in the memorial are:—*a*. The reaffirmed rule of the Committee of Management under which they may be sent back to studies after rejection; *b*. The alleged excessive diploma fees; *c*. The alleged excessive re-examination fee; *d*. The want of proper accommodation for luncheon, &c., in the College school. A general meeting of the students was held, by permission, in the College theatre, when a Students' Association was organised, which we hope will be managed on discreet and business-like lines, in which case the success of all reasonable representations to the Colleges is assured. There are plenty of real grievances to be remedied, and perfectly reasonable concessions to be asked for. Moreover, in our opinion, the College may gain much useful information by inter-communication with the students, but we are sure that the organisers of this movement have sense enough to see that it will be impossible for the Colleges to yield to any proposals which would lower the standard of education or examination, or to engage in controversies as to the fairness of individual examinations. We therefore trust that the students, for their own sakes, will keep carefully clear of such pitfalls.

Medical Officers of Health and Infectious Diseases.

AN ever-present danger of open friction between the general practitioners and the medical officer of any given district lies in question of diagnosis. Some time since a case was commented on in these columns where the notification fee of a medical man in a central London district was refused by the Vestry on the ground that the disease was other than the one certified. To uphold his own adverse view the medical officer called in a "specialist in erysipelas," whatever that may mean, from the West End. The plaintiff doctor, however, recovered his fee from the Vestry. In view of the possibility of such unseemly wrangles, it is encouraging to find Dr. Louis Parkes takes the following decisive view of the position in his lately published little handbook: "There is no obligation laid upon the Medical Officer of Health to examine a patient notified by a medical practitioner as suffering from an infectious disease in order to *verify the diagnosis*. Such a procedure forms no part of the duty of a Medical Officer of Health. . . . As a general rule the examination of a patient should only be made after obtaining the consent of the medical practitioner in attendance, or in consultation with him."

A Protest against Notification.

IN another column will be found a letter from a correspondent which confirms in many particulars the justness of our opposition to this measure as at present administered. In our opinion the system of compulsory notification by the medical practitioner cannot be "mended" and must be "ended." It is, and always was, intrinsically bad in principle, and it would have been wonderful if the wrangles between the sanitary authorities and the practitioners which now threaten the life of the system had not occurred. They are part and parcel of the method, and of themselves are enough to kill the system, but there are many other faults which would certainly destroy it even if the doctors had nothing to complain of. Why should not all parties join in getting rid of this legislative monstrosity and replacing it with an Act which may secure immediate and effective notification by other means? All are agreed that it is very desirable to attain such a result. Why should we continue to discredit the principle by sticking to a mechanism which is entitled to no respect (being the deformed offspring of half a dozen faddists), is vicious in principle, unworkable in practice, and pernicious if it were worked? Let us all insist on a repeal of the dual notification system and the enactment of compulsory notification by the householder, aided by such inducements for voluntary notification by the practitioner as will put the working of the system practically into his hands.

The Practitioners' and Students' Registers.

THE official lists annually issued by the General Medical Council reach us this week, much earlier in the year than has been customary, for which Mr. Miller, the Registrar, is entitled to special credit. To those who can take time to look over the statistics contained therein, the books contain much interesting information. The numbers of our profession continue steadily to increase. The 22,200 of a medical army in the field in 1876 has grown to 31,614, the increase being at the rate of over 500 each year. Recently the growth of the profession has been more rapid, and since 1893, 1,579 names were added to the list, making a net addition, after all deaths are allowed for, of 1,054 new practitioners. Nothing is more striking in these figures than the growth of the business done by the Scotch and English Licensing Bodies at the expense of the Irish Colleges. In the 13 years from 1876 to 1888, England increased its yearly average output of practitioners from 676 to 699; Scotland increased hers from 306 to 525 (over 58 per cent.); while the Irish output fell off from the yearly average of 211 to 177 (a decrease of 13 per cent.) A marked feature with regard to the Register is the increase in the number of Licensing Bodies in the British Colonies and India which have been recognised by the Medical Council as granting qualifications entitling to registration in the Colonial List, the following bodies having been added to those previously recognised: the Universities of Adelaide, Calcutta, Madras, and the Punjab, and the Ceylon Medical College. The Students' Register, heretofore issued in paper covers, has risen to the dignity of cloth boards, and is otherwise much improved. Among other interesting things which may be learned from its pages is that the adoption of the five years' scheme of education produced an immediate loss to teachers, colleges, and hospitals throughout the Kingdon of no less than 734 students, a drop in one year (1892) of over 30 per cent in the student class. It is much to be regretted that professors, hospital surgeons, and collegiate administrators do not seem to be able to spare a little time from less edifying avocations to study the figures which these books contain and to make some attempt to stem the tide which promises to sweep them away.

DR. WM. JEPHSON WELDON, of Gorey, has been appointed to the Commission of the Peace for the County Wexford.

The Death of the Coroner for North-East London.

WE regret to announce the death of Dr. Roderick Macdonald, Coroner for North-East London, and lately M.P. for Ross-shire. Some months ago it was reported that he was suffering from epithelioma of the tongue, and his illness compelled him to assign his duties to a deputy. The appointment was worth £1,600 per annum. Formerly the freeholders elected the coroner, but now the election to the post is in the hands of the London County Council. We trust that another medical man will succeed to the vacancy thus created by Dr. Macdonald's death. There will doubtless be a large number of applicants for the appointment. At present only one has come to our knowledge, that of Dr. Bernard O'Connor, who possesses the undoubted advantages for such a post, being both a doctor of medicine and a barrister-at-law.

The Agitation against the British Institute of Preventive Medicine.

A CORRESPONDENT referred last week to the antics of the clerical quack—the Rev. R. H. Haweis—against the building of the Pasteur Institute at Chelsea, and the manner in which the agitation is still carried on is superbly exposed in a communication which we publish in another column from Dr. Armand Ruffer, the Honorary Secretary to the Institute. But despite the opposition of Haweis and Co., the public have shown themselves capable of reading between the lines, and with commendable common sense have declined to take part in an agitation the promoters of which have declined to take part in an agitation the promoters of which have been painfully convicted of malicious ignorance in respect to the subject concerned. It is not surprising that the "Rev. Mr. Puff" should have espoused the cause of the Anti-Vivisection Society, for this Society happens to be *the one* of all others which makes the most fuss about itself, and out of which the most notoriety is to be gained at a cheap rate. After all, however, no serious notice need be taken of the screechings of these fatuous agitators; the public, we are glad to say, has more sense than is sufficient to appraise them at their true value.

A CHELTENHAM correspondent states that a profound sensation was caused there on Saturday evening by Dr. C. Neil Griffiths having been found in his surgery shot through the heart. He recently suffered from a severe attack of influenza, which caused a low and depressed condition. Arrangements had been made for a trip to Bournemouth for a change at the time of the tragic event. The pistol was found in the surgery.

WE observe with satisfaction that Dr. Robt. L. Swan, Surgeon to Steevens's Hospital and the Orthopædic Hospital, Dublin, has returned to Dublin completely restored to health. Having suffered last autumn from a dangerous attack of typhoid fever, he, by the advice of his physicians, took a trip to India and back with the best result to his health.

THE recent death of Dr. Charles MacDowell, of Carlow, extinguishes the office of Visiting Physician to the District Asylum, and an election was held last week for the purpose of appointing an assistant, who is supposed to balance the loss of the Visiting Physician, the salary being £200 a year. Two candidates presented themselves, and the result of the voting was a tie, so that a fresh election must be held.

WE are asked to announce that in consequence of the absence of Dr. Thorne-Thorne from England on official duties, he will be unable to give his address on "Cholera" at the Sessional meeting of the Sanitary Institute on March 14th.

THE Dispensary Medical Officer of the Golden Bridge Dispensary found, last week, in the infusion jug, the decomposed body of an infant. The vessel had, however, not been used for years.

THE death is announced of Dr. David Davies, J.P. for Carmarthenshire, aged 76, at Aberceri, Newcastle-Emlyn, South Wales. For twenty years the deceased held the post of Medical Officer of Health at Bristol, resigning in 1886.

DR. GILBART SMITH has succeeded Dr. Hughlings Jackson in the physiciancy of the London Hospital. In consequence of this promotion a vacancy is created on the staff of assistant physicians.

DR. NORMAN ANWYL has died at Rio de Janeiro of yellow fever, which is raging severely in the Bay. A telegraphic despatch states that there were 200 cases of the disease in that city last week.

PROF. W. C. ARNISON and Dr. James Murphy have been selected as delegates to represent the University of Durham at the International Medical Congress at Rome.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

THE ALLEGED INCREASE OF LUNACY IN SCOTLAND.—At the quarterly meeting of the Scotch Branch of the Medico-Psychological Association, held at Glasgow on Thursday, 8th inst., under the presidency of Dr. Ireland, the agenda was not exhausted because of an interesting discussion on the certification of the insane in the Barony parish of Glasgow. This subject was introduced in an elaborate paper by Dr. Carsewell, who occupies a unique position as special certifying physician for the parish. His business is to examine carefully into every alleged case of lunacy, and where the mental disorder is one of doubtful lunacy, or transient, to send the case to special observation wards in the workhouse, and thereafter if need be to the asylum. He furnished some startling statistics. By this rigorous method of scrutiny, he has been able to reduce the number of certified lunatics to less than 60 per cent. of the applications. Moreover, the duration of treatment in the observation wards is never more than a month. The subject was next handled by Dr. Alexander Robertson, who has had considerable experience in certifying lunatics, by Drs. Clouston, Campbell Clark, Urquhart, Watson, and others. Mr. Motion, the Inspector of the Barony parish, gave much practical information on the method of dealing with these transient and borderland cases in the observation wards. The general feeling of the meeting was that much fresh light had been shed on the problem of the alleged increase of lunacy, that this experiment, successful though it has been in the case of the Barony parish, ought to be carefully conducted in view of possible neglect and abuse in workhouse wards, and that it might be compared for statistical purposes with the results obtained in other large parishes of Scotland.

Edinburgh Refuse.—The old question of the disposal of the Edinburgh refuse has again been re-opened by an action brought by the Lord Advocate on behalf of the War Office, seeking to interdict the North British Railway Company and a farmer from conveying refuse to Glencorse or from unloading it near the military barracks there. At present a very considerable quantity of the town refuse is destroyed in the destructor recently erected, but all of it cannot be got rid of in that way, and the Town Council sell some to farmers or fill up disused sand pits, &c., in the neighbourhood of the city with the rest. In the course of the action it was shown that although the refuse had an evil smell, yet it contained no fæcal matter, save some small quantity of horse-droppings, and was unlikely to set up disease. Dr. George Balfour, who was examined for the defence, when questioned about the possibility of growing organisms from the stuff, showed the Court test tubes cultivations of germs grown from Edinburgh bread and Edinburgh water, no doubt much to the Court's astonishment, and said that germs could be cultivated from almost any mortal thing. It was also pointed out that in the barracks themselves there were at least fifteen dustbins containing the same quality of house refuse as that complained of. Local medical evidence was led to the effect that no cases of diphtheria or typhoid had been traced to the refuse, and that the health of those living near the depôts had not been affected. The Court reserved judgment.

Edinburgh Royal Infirmary.—The Law Committee, to whom the question of the powers of the Board of Managers to attach conditions to future staff appointments was remitted, have reported that, "The Committee are of opinion that the Board has power to limit the tenure of office of members of its staff to one year, and to attach to the appointments such conditions not inconsistent with the Charter or Act of Parliament, as it sees fit." Dr. Batty Tuke, at the meeting at which this report was handed in, said that this report did not touch the crux of the question whether the Board had a right to limit the franchise of any body that sent members to the Board. He moved that the report be referred back to the Law Committee, but found no seconder, and the report was approved.

Grants to Glasgow University.—The Bellahouston Trustees have notified the following grants to the University:—(1) a capital grant of £5,000 towards the erection and equipment of buildings for medical and scientific instruction of students; (2) a capital grant of £500 and an annual grant (during the pleasure of the trustees) of £100 on account of the University library; (3) a capital grant of £500 and an annual grant (during the pleasure of the trustees, of £100 towards the pathological section of the Hunterian museum; (4) £5,000 towards the establishment of a chair of geology; two annual grants of £100 each, and a grant of £500 towards chairs of natural philosophy and chemistry; £400 on account of a chair of physiology; a capital grant of not less than £750 nor more than £1,000 on behalf of a chair of astronomy; and an annual grant of £50 for five years towards improving the condition of the Observatory.

The Scottish Universities—Draft Ordinances.—A number of draft ordinances have just been issued, the most important being Nos. 19 and 20, the former containing general regulations for the admission of women to bursaries, scholarships, and fellowships. The other draft ordinances are "Glasgow, Nos. 8 to 19," and consist of regulations for the various foundations, and the foundation bursaries. It is proposed that the four foundation bursaries should be conjoined into two, each of £20 per annum, tenable for three years. Bursaries open to students entering on their first session of medicine will be tenable only by students who have passed the preliminary examination in medicine, or who have been exempted in accordance with provisions of Ordinance No. 49, 14, 15 or 16, and who have not attended any class qualifying for graduation in medicine. With reference to the admission of women to bursaries, the University Court has the power to make regulations for the purpose of appropriating for competition among women students only who are proceeding to a degree in any faculty, open bursaries, which have taken effect prior to the 30th day of August, 1864, with certain reservations. Women will not be allowed to compete for or hold any bursary, scholarship, or fellowship which is not expressly open to competition by women, by the terms of its deed of foundation, and women competing for bursaries, scholarships, or fellowships under the provisions of this ordinance will be subject to all the provisions prescribed by Ordinance General, No. 19.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE BRITISH INSTITUTE OF PREVENTIVE MEDICINE AND THE ANTI-VIVISECTION SOCIETY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As the Victoria Street Society for the Total Abolition of Vivisection has taken a prominent part in the agitation against the erection of the Institute at Chelsea, and as notice has been taken of this agitation in your columns, it seems only right that the profession and public should be informed of the way in which this war against scientific investigation is carried on. I beg therefore to ask you to be good enough to find a space for the enclosed document which was written by the assistant-secretary immediately after the conclusion of the interview, and I may add that I am prepared to take every responsibility for the statements made in it.

For the information of your readers it may be stated that Arthur Westcott is a professional lecturer of the Victoria Street Society and has lately been employed in getting up an agitation in Chelsea and the neighbouring parishes against the British Institute of Preventive Medicine.

I am Sir, yours, &c.,
W. Armand Ruffer.
Hon. Sec. Brit. Institute of Preventive Medicine.

101 Great Russell Street, London, W.C.,
March 6th, 1894.

This morning a person called at the office of the Institute, at 101 Great Russell Street, to ask for particulars concerning the Institute, as he said he had seen a letter in the Chelsea papers by Dr. Ruffer stating that information would be given to all who applied to Dr. Ruffer for it. On my leaving the room to inform Dr. Ruffer, the man sat down at my desk and was seen by Dr. Ruffer and myself to be reading the documents which happened to be lying about.

On Dr. Ruffer asking him his name, he gave it as "John Vernon" of the Kingsland Road, Chelsea. Dr. Ruffer told him this was not true, that his name was Arthur Westcott, and that he was the paid agitator of the Victoria Street Society. This he stoutly denied over and over again, but as I knew the man by sight and told him I had heard him lecture under the name of Westcott, he at last owned that he had what he called a "double-barrelled" name, and that in full it was Arthur John Vernon Westcott. Dr. Ruffer pointed out that he never had so signed or so initialled his name and asked him if he thought it was honest to say his name was John Vernon when it really was Arthur Westcott, and his reply was that if he had given his proper name he thought it most probable that he would not have been able to obtain the information he wanted. Dr. Ruffer told him that as he had been lecturing at Chelsea during the last fortnight about the proposed Institute, common honesty required that he should have made his inquiries *before* beginning to lecture. Dr. Ruffer added that he, Westcott, had never once asked for information about the proposed Institute, and the members of the Victoria Street Society had never made any endeavours or any inquiries at the office to ascertain the true aims and objects of the Institution they are now abusing, and that, moreover, many of the statements which had been published by him, Westcott, and by various other members of the Anti-vivisection Society were simply deliberate falsehoods. Westcott was then given all the documents in my possession relating to the objects of the Institute. This having been done, Dr. Ruffer told Westcott that to come as a spy into a man's office and give a false name was nothing short of telling a lie, and that he, Westcott, was a liar and an impostor. Westcott said he did not think so. On taxing Westcott with uttering falsehoods at the meetings he addressed, Westcott said this was the reporters' fault, but immediately afterwards admitted that he himself had given his notes to the reporters. He then took a written lecture out of his pocket, and began quoting passages from it, but Dr. Ruffer remarked that this was perfectly unnecessary, as he, Dr. Ruffer, already had a shorthand *verbatim* report, taken by two reporters, of everything that was said at one of the meetings addressed by Mr. Westcott.

On Dr. Ruffer asking him to substantiate his statement that he had seen cultures thrown out of a window at the Institut Pasteur, he denied ever having said such a thing, and admitted he had never seen this done. When Dr. Ruffer charged him with having described as an eye-witness an experiment at the Institut Pasteur, which had never been performed there, Westcott admitted that *he had never seen any experiment whatever at the Institut Pasteur*, but he had seen the experiment in "another laboratory." He did not volunteer the name of the "laboratory," nor the date of the experiment, but Dr. Ruffer pointed out that from the shorthand report, he distinctly understood the supposed experiment had been done at the Institut Pasteur, and that he, Dr. Ruffer, had also in his possession the report of another of Westcott's speeches, in which he described how he, Westcott, had seen over five hundred animals inoculated at the Institut Pasteur, and that in many cases great pain was caused. Westcott again stated he had never seen a single experiment performed at the Institut Pasteur, and was then shown the door.

Geo. N. Cooper, Assistant Secretary.

THE CHELSEA HOSPITAL FOR WOMEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am instructed by the Board of Management to write you as follows :—

You are aware that the Vestry of Chelsea had asked of the Home Secretary and the Local Government Board an inquiry into the management of the hospital during the past year. Both these authorities have refused to institute such an inquiry.

The Board of Management and the Medical Staff would have welcomed the most searching investigation by either the one or the other. However, the Vestry's demands having been refused by the Home Office and the Local Government Board, we are free to address you. Herewith are presented to you full and accurate details of the four classes of operations as to which the Medical Officer of Health for Chelsea makes special reference, and they are tabulated in such a way as to answer the five questions he asks as to each class. Moreover, the name of the operator is appended to every case. We make our reply in this form, although we do not for one moment admit the right of any Medical Officer of Health, however distinguished in his own speciality, to set himself up as a judge of the operative work of this or any other hospital in his district. We venture to submit that to do so would be to set up a most dangerous precedent.

We believe this is the first instance where any Medical Officer of Health has, in a statement made professedly as to the insanitary condition of a hospital, taken occasion to make an attack upon the entire Medical Staff reflecting upon their professional probity and skill. It is needless so say that had these reflections been directed against any single member of the Staff, Dr. Parkes would have been proceeded against for libel and defamation of professional character, from which even his official position would not protect him.

During the year under review 28 patients remained in the hospital from the previous year, and 636 new cases were admitted, making 664 under treatment. Of this number 373 required operation. Thirty-five women died, a general percentage mortality of 5·2 per cent. Of the 35 deaths, or 36, as has been alleged, including a prematurely born child, 13 never were operated upon at all. The death-rate amongst those not operated upon was, therefore, 4·9 per cent. This proves to demonstration that during 1893 the class of cases brought to us for treatment was one of patients in the last stages of illness. Our books show that the ordinary formalities of obtaining letters had again and again to be dispensed with, and that desperate cases were admitted simply in the common cause of humanity. Doubtless in this way some unsuitable cases were received, but it must be remembered that an accurate diagnosis cannot be made of obscure internal disease till after admission. Once admitted we felt the responsibility of doing our best must be borne, and that it would be inhuman to turn the poor creatures out again merely to keep our statistics in a condition favourable to the Medical Staff. In this way at least 14 cases more or less septically infected before admission came into our wards and unquestionably exerted a malign influence on some of our other cases.

It is manifestly unfair to take one year's work and upon that to credit us with a death-rate of so many per cent. for this or for that operation.

It is no more right for the Medical Staff to be specially blamed because the percentage of deaths of ovariotomy cases has been higher in 1893 than in any previous year, than it is for them to claim undue praise because in six cases of extra-uterine gestation operated on in the same year, there were absolutely no deaths. The whole question thus raised as a side issue to the insanitary condition of the hospital bristles with fallacies. As to the sanitary report as laid before the Vestry of Chelsea by Dr. Parkes, it involves that gentleman in a serious charge of misrepresentation and neglect. We do not stop to dwell upon the fact that he has recommended that the main drain of the hospital be carried inside the building, whereas it has been hitherto outside, nor that on many other points he is in conflict with other distinguished sanitary authorities. Nor do we stop to plead that everything and every appliance that was regarded as sanitarily perfect was used regardless of expense when the Hospital was built 14 years ago.

The gravamen of his charge is that he made his way into the hospital, that he discovered the insanitary condition of the hospital and that he felt compelled to apply to the Vestry to close the hospital on Feb. 6th, 1894. Whereas the first case of scarlet fever occurred on 27th Dec. 1893, the hospital was closed on my initiative on the 29th Dec. 1893, five weeks before he presented his report, be it noted. No patients were ever infected ; three nurses were laid up with the fever, not four, as he states ; so promptly were they isolated and removed, that in three days the outbreak was over.

After closing, steps were taken to clear the hospital as speedily as could be done with due regard to the safety of convalescent patients ; on Jan. 15th the hospital was empty. In the meantime it had been resolved to place the institution in the hands of the Medical Officer of Health for disinfection and general inspection. On 17th, 19th, and 20th Jan., the Medical Officer of Health inspected the hospital, and on the 22nd, by invitation, attended a meeting of the House Committee, making a verbal report and generally advising. On the 24th his written report was received as to suggested sanitary improvements. Plans and specifications were forthwith got out and tenders invited.

On Feb. 3rd, 1894, I wrote Dr. Parkes to the effect that his recommendations would be carried out. On Feb. 2nd, 3rd, and 5th, the sanitary engineer of the hospital waited upon Dr. Parkes with the plans embodying his suggestions, and was refused an interview on each occasion. Yet in the face of all this, regardless of what injury it might do to an institution which had been established 21 years, officered by men all working with the common object of saving life and relieving suffering, he thinks fit to present a report to a body of laymen reflecting on the professional probity of certain of his medical brethren and asking for powers to close a hospital which he well knew had been shut for five weeks, and in which he knew public money was being expended to carry out loyally every recommendation, reasonable or otherwise, which it had seemed good to him to make.

So serious a view does the Board of Management take of

Dr. Parkes' proceedings that they are making representations embodying all these facts to the Home Secretary, to the President of the Local Government Board, and the Chelsea Vestry.

I wish I could have made this letter shorter, but the wide scope of the charge makes a brief reply impossible.

I am, Sir, yours &c.,
Henry E. Wright,
Treasurer.

Chelsea Hospital for Women, Fulham Road, S.W.
March 6th, 1894.

◆

INFECTIOUS DISEASES (NOTIFICATION) ACT, 1889.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—May I point out what must be regarded as a grave defect in the Infectious Diseases (Notification) Act, 1889, and one which I have little doubt will have to be remedied sooner or later. I refer to the facility it affords for grave misuse by putting in the hands of the smallest sanitary authority, and hence into the hands of their advisory and executive officers, the power to summon vexatiously, and on totally inadequate evidence, respectable medical practitioners to appear as defendants in a police-court with its inseparable criminal associations.

Unreasonable prosecutions under the Act are becoming unpleasantly common. In one instance a purely unintentional omission to notify, an omission which any medical man in busy practice can understand may readily happen, led to such a police-court prosecution.

Moreover, it has become common for village medical officers of health to so misread their powers as to visit the patients of their brethren, and to assume that it is one of the functions of their office to sit in judgment on the diagnosis of their fellow and rival practitioners. In a recent case the Local Government Board issued a letter pointing out the impropriety of such action, but this surveillance on the part of the medical officer of health has led to several recent prosecutions and threats of prosecution.

The members of small authorities not unfrequently think they constitute a proper tribunal to decide obscure questions of diagnosis, and regard their medical officer of health as their skilled assessor. Consequently, a word from him is sufficient for them to decide on a prosecution under the Act. As an example of the confusion and improprieties which take place, I quote another case :—

A small sanitary authority, because, as they allege, "their medical officer had carefully diagnosed the case," (*sic*) of another practitioner, refer the matter to a still smaller committee with a view to prosecution under the Notification Act for the non-notification by the practitioner of disease which, in his opinion, did not exist; and in spite of one clear-headed member of the board who, although personally unacquainted with the practitioner in question, protested that a committee is not competent to deal with such a matter, and who publicly maintained that many of these prosecutions "were the result of caprice, personal feeling animus on the part of the officers, and perhaps some of the members of the board."

Again, prosecutions have followed omission to notify cases in which the signs render a certain diagnosis absolutely impossible, and one learned clerk to an authority is reported to have delivered himself thus :—"The Act was passed in order that diseases which, in the opinion of medical men, were *likely to develop into one* of those mentioned in the Act might be notified at once." This, in spite of the clear language of Section 3, which says :—

"Every medical practitioner . . . shall forthwith, on becoming aware that the patient is suffering from an infectious disease . . . send to the Medical Officer of Health . . . . . . a certificate."

What I ask, Sir, is this: Is it right, reasonable, or conducive to the maintenance of its honourable status that the members of a generous and public-minded profession should be subject to the indignity of a police-court prosecution instituted by an authority acting under the guidance of officers who can read the plain English of Section 3 in this way, or of medical officers equally fallible as themselves, and whose worldly interest is to discredit their rivals?

Let us have notification by all means as a basis for isolation, but let the profession have some security and protection from persecution originating in ignorance, conceit, rivalry, or other improper motive. The remedy is to amend the Act, so that the veto of prosecution shall be vested in the Local Goverment Board. This is the only feasible way to save an otherwise beneficent Act from ultimate inevitable repeal.

I am, Sir, yours, &c.,
Leslie Phillips, M.D.

Birmingham, March 7th.

◆

A MECHANICAL TREATMENT OF PHTHISIS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I am glad to see that this subject has interested at least one of your readers. If the value of the plan I described were recognised as I think it deserves to be, every case in which phthisis threatened or had commenced would be treated in the manner I proposed.

Mr. Huxley remarks that I make no allusion to the use of crutches for frequent exercise. My reasons for disapproving of crutches for such a purpose are as follows :—

1. They press the shoulders upwards and rather forwards, and tend to compress the apices of the lungs, and not to expand them.
2. The use of crutches involves very great physical exertion on the part of the patient.
3. They press upon the axillary vessels and nerves, which is, to say the least, very irksome to the patient, and may be harmful.

Even if crutches acted as beneficially as the plan I advocate, there would still be the objection that its effect would only be temporary, whereas, one of the chief points of my proposition is the *continuous expansion* of the thorax with hardly any effort on the part of the patient.

Of course there are cases of difficulty in walking from paralysis and other causes in which crutches may be used, but even in such instances I always prefer adapting, when possible, other methods of helping the patient rather than impose upon him the disagreeablenees of getting about with such primitive apparatus as crutches.

I am glad to see that Mr. Huxley advocates the use of a tricycle of an improved form, and I hope he will invent something upon the lines he suggests.

I am, Sir, yours, &c.,
Noble Smith.

Queen Anne St., London, W.

THE INVENTION OF THE FLAP-SPLITTING OPERATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Questions of priority are always the most useless for discussion, and at the same time the most aggravating. Concerning that which forms the heading of this letter, my friend, Dr. Alexander Duke, does me scant justice. When my original paper was published (I think in 1888), some one then in Dublin sent me an anonymous letter (the authorship of which I now suspect) pointing out that Maurice Collis had anticipated my idea for vesico-vaginal fistula so long ago as 1861. I immediately wrote a letter to the journals pointing out the fact, delighted at the same time that I could render a tribute to one who was one of my most highly-esteemed friends.

But in my operation for repair of the ruptured perinæum the principle of flap-splitting is but one of a number of processes, the rest of which do not come within the scope of Maurice Collis's paper. If any body else had combined them and applied them before I did, so much the better for him, but I may say that I repudiate every description of my operation written by any body who has not seen me do it.

I am, Sir, yours, &c.,
Lawson Tait.

Birmingham, March 12th, 1894.

Obituary.

MR. J. K. BARTON, OF DUBLIN.

The news arrived in Dublin last Sunday morning that Mr. Barton, Surgeon to the Adelaide Hospital, had breathed his last at Mentone, where he had gone for the benefit of his failing health, resided and practised for the last two winters. He had spent a portion of last summer in Dublin, and returned to Mentone with the advent of the cold weather. Mr. Barton was the son of a well-known banker and stockbroker in Dublin. He entered the profession through the University of Dublin, in which he graduated as B.A. in 1854. He had taken the licence of the College of Surgeons two years previously, and he became a Fellow in 1860. He was at first connected with the Anatomical School of Trinity College, where he held successively the positions of Demonstrator and University Anatomist, and, afterwards, he joined in laying the foundation of the Carmichael College, in which he was Lecturer on Surgery for several years. He became President of the College of Surgeons in 1883, and was Senior Surgeon of the Adelaide Hospital until his death. Mr. Barton had the mind and spirit of a gentleman. Unassuming and kindly, incapable of an act which was disingenuous, and strongly influenced by religious feeling, he manifested none of that Pharisaism which commonly marks the ostentatiously pious. He married the daughter of the famous Professor of Chemistry in the University, James Apjohn, and, in dying, has left hosts of regretful friends, and, we believe, not one enemy.

DR. DAVYS, CORONER FOR NORTH DUBLIN COUNTY.

We greatly regret to announce the death of Frank Davys, the genial Coroner for North Dublin and Medical Officer of the Swords District. Dr. Davys breathed his last from cardiac asthma. He had been in delicate health since last summer, and after partial recovery, had strained his weakened constitution in the brave effort to perform his duty and to carry on his work, but had been obliged to stop work some weeks ago and come to Dublin for medical help. Dr. Davys was a model of characteristic Irish intelligence and hard work. He was, so to speak, in the saddle night and day in the endeavour to keep pace with a large local practice and with his coroner's duties, and he was most successful in the effort, for he enjoyed the confidence of his patients and never made mistakes in his legal functions. He was almost as well known and as popular in Dublin and amongst his professional colleagues in his College and in the Academy as in Swords, and for many years occupied a position as Examiner in the College of Surgeons.

Medical News.

The International Medical Congress at Rome.

The English Secretary is anxious that members should understand that travelling vouchers only are issued by him in the first instance. The Secretary then has to give notice to the Italian authorities, and the provisional cards (white for members, red for guests) referred to in the blue printed circular are sent from Rome. Application has been made to the Italian Committee for a supply of the provisional cards, and if this can be granted time may be saved. The English Secretary also would be particularly obliged if all applications for tickets could be made as soon as possible, in order to avoid possible difficulties which may result from hurried issue at the last moment. Since last week the Sleeping Car Company (46 Rue Mathurien, Paris) has accorded a 50 per cent. reduction, which brings the extra cost for sleeping accommodation down to the same proportion as that charged for ordinary tickets.

The Truth about Bovril.

From time to time reports have been circulated that the extract of meat known as "Bovril" was made from horseflesh, and no sooner was an authoritative denial given than the rumour cropped up in another quarter evidently showing that either the report was true, or that some agent was maliciously bent on injuring the reputation of a popular article of diet. That "truth will out" is fully exemplified in the present instance. Last week an action was brought by the Bovril Company, of which Lord Playfair is Chairman, in the Scotch Court of Session against a horse-dealer and foreign agent, of Glasgow and Greenbank, for damages for libel. The plaintiff Company stated that they carried on an extensive business as food specialists and as the manufacturers of the fluid beef preparation known as "Bovril"; that Bovril is the guaranteed product of prime ox beef manufactured exclusively from the flesh of first-class oxen in the very best condition; and that it is manufactured under the constant direct supervision of Dr. Harkness, Government Analyst, Somerset House, London. They alleged that since the formation of the company in 1889, there had been generally a large and steady increase in the amount of Bovril sold, but that in certain districts there had been, during the last two years, a decrease in their sales, and in the course of their inquiries they discovered that the defendant, who is a foreign agent in Glasgow, had regularly and systematically since the beginning 1892, represented himself as being the agent employed by the Bovril Company to buy old horses and solicited horse dealers and others to sell him such horses for the purpose of being manufactured into Bovril, and that he had regularly bought horses which he stated were purchased for that purpose. The pursuers characterised these statements as false and calumnious, and they alleged and offered to prove that they were so, and that they had no connection with the defender, or even employed him in any capacity, but that in reality the horses purchased by the defender were shipped by him to the Continent. The result of these false and calumnious statements was that many persons both among those to whom the defender made the statements and others to whom the report had spread, ceased to use Bovril and advised their friends not to use it. The action resulted in a verdict for the plaintiff Company with £1,000 damages and costs. We congratulate the Company upon having discovered and punished the author of this scandalous report.

The Anniversary Dinner of the Medical Society of London.

The one hundred and twenty-first anniversary dinner of the Medical Society of London was held on Thursday last, March 8th, at the Whitehall Rooms, Hotel Métropole, Mr. Arthur E. Durham, F.R.C.S., Treasurer and past President, in the unavoidable absence of the President, Dr. Bristowe, F.R.S., occupying the chair. There was a large attendance, and the *réunion* in every respect was a most successful one. Among those present, including guests, we noticed the President of the Royal College of Physicians (Dr. Russell Reynolds), the President of the Royal Medico-Chirurgical Society (Mr. Jonathan Hutchinson), Professor Bardeleben, the Presidents of the Harveian and Hunterian Societies, Dr. Marcet, F.R.S., Dr. Wilks, F.R.S., Sir Joseph Fayrer, and several past Presidents of the Society. In the toasts that followed, the Chairman gave the "Queen and the Royal Family," and the "Medical Society of London." "The President" (Dr. J. S. Bristowe, F.R.S.) was proposed by Dr. C. Theodore Williams, and in reply, a letter from Dr. Bristowe, regretting his inability to be present through illness, was read by the Chairman. "The President-elect" was proposed by Mr. Thomas Bryant, and responded to by Sir William Dalby. "The Visitors" was proposed by Mr. Howard Marsh, to which Dr. Eastes and Professor Bardeleben replied. Dr. Douglas Powell then proposed the "Retiring Officers and Members of Council," and this was acknowledged by Dr. Cullingworth, retiring Councillor, and Dr. Pasteur, retiring Hon. Sec. Lastly, the "Health of the Chairman" was proposed by Dr. Roberts and responded to by Mr. Durham. The Bijou Orchestra performed a selection of music during the dinner, and Dr. Frederick Roberts kindly sang a song to the delectation of the company. We may add in conclusion that the Officers of the Society, in the course of their speeches, referred in warm terms to their indebtedness to Mr. Hall, the Registrar of the Society, in respect to the assistance which he had rendered them in conducting the Society's work during the past year.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 34, Bombay 36, Madras 44, Paris 23, Brussels 19, Amsterdam 18, Rotterdam 21, The Hague 17, Copenhagen 20, Stockholm 17, Christiania 21, St. Petersburg 27, Moscow 29, Berlin 17, Hamburg 21, Dresden 22, Breslau 24, Munich 25, Vienna 26, Prague 32, Buda-Pesth 24, Trieste 39, Rome 21, Turin 32, Venice —, Cairo 49, Alexandria 53, New York 23.

Notices to Correspondents, Short Letters, &c.

ACCEPTED LECTURES, PAPERS, AND CASES.

The following are hereby acknowledged:—

Dr. Symes Thompson: Post-Graduate Lecture on Phthisis and Life Assurance.

Mr. Jonathan Hutchinson: Post-Graduate Lecture with Clinical Demonstrations.

Dr. Macnaughton Jones: On a Gynæcological Question of Importance in Forensic Medicine relating to the Hymen.

Dr. Lewis Jones: On the Electrical Treatment of Infantile Paralysis.

Dr. F. P. Atkinson: Some Results of Influenza, their Method of Treatment.

Prof. Kraft-Ebing: Clinical Lecture on Poliomyelitis Anterior Acuta, simple and complicated with Multiple Sclerosis.

Prof. Max Jolles: Clinical Lecture on the Examination of the Urine for Nitrites.

Dr. Chas. Forbes: On Malaria and its Therapeutics.

Dr. Macnaughton Jones: Some Practical Observations on the Examination of the Ear.

Mr. Roger Williams, F.R.C.S.: A Clinical Study of Rodent Ulcer based on twenty-eight cases.

Dr. A. Scott Myrtle: How Chronic Skin Diseases were Affected by the Continuous Heat of Last Summer.

Mr. W. H. Horrocks, F.R.C.S.: On Ovariotomy followed by Melancholia.

THE OATHS ACT AND MEDICAL WITNESSES.

To the Editor of The Medical Press and Circular.

Sir,—Having always taken much interest in this subject, and knowing how very repulsive is the act of kissing the grimy book to many medical and other witnesses, I am very glad that you have taken up the cause so warmly and published a copy of the Act.

A little firmness and persistence on the part of medical witnesses would make the Scotch oath, as it is called, general among most witnesses and jurors; for kissing the book is almost confined to England, Wales, and Ireland. The uplifted hand prevails on the Continent, in America, and elsewhere.

Yours faithfully,—F. W. L.

Dr. Lewis Jones' paper on "Electrical Treatment in Infantile Paralysis" is unavoidably hold over.

THE ARMY AND NAVAL COMPETITIVES.

In addition to the examination for fifteen vacancies which is advertised by the Naval Medical Department to come off on the 7th of May, the Indian Medical Department has announced that twelve appointments in that service will be filled by competition in August next.

Mr. Atkinson's paper is accepted, but is necessarily held over on account of the great pressure on our space.

THE COOMBE HOSPITAL SCANDAL.

In a recent issue we reported that a settlement of the suit of the late Master of the Hospital, Dr. Hoey, against the *Independent* newspaper, had been arrived at, the paper agreeing to pay £40 and costs. The *and* was a printer's interpolation, the truth being that the total payment in respect of costs, &c., was £40, and no damages were awarded.

Dr. F. W. Lowndes (Liverpool).—Letter received as we were at press. It shall appear in our next.

THE DICKINSON TESTIMONIAL.

The Hon. Treasurer asks us to make known the fact that the subscription list of the Dr. W. H. Dickinson Testimonial will be closed on the 31st inst. Intending subscribers, therefore, should send their subscriptions to T. Lawrence Read, Esq. (Honorary Treasurer), 11 Petersham Terrace, Queen's Gate, London, S.W., before that date.

Aliquid.—We received the journal with the article in question, but did not consider it worth criticism in our columns. *De minimis non curat lex.*

INSURANCE ON A SMALL SCALE.

A curious item in the report of the Pearl Insurance Company is that relating to the sickness insurance account. No new business, says *London*, has been taken in this branch for twenty-six years, and all that is now being done with it is to receive premiums from old insurers and pay them when ill. Last year the premiums were only £10 5s., and the sick pay £14, and the total fund in hand is only £165.

Dr. P.—The "Sirop de Gibert" is a preparation of the biniodide of mercury, and in one form or another can be obtained at most chemists.

Perplexed.—The law imposes no responsibility on you except as a medical man. The Coroner's officer is the proper person to deal with the other responsibilities.

Meetings of Societies, Lectures, &c.

Wednesday, March 14th.

Laryngological Society of London (20 Hanover Square, W.).—At 5 p.m., Dr. J. B. Ball: A case of Fixation of Vocal Cord of doubtful origin.—Dr. De Havilland Hall: (1) Closure of a Tracheal Fistula of Twenty-one Years' Duration; (2) Larynx of Patient previously shown with Syphilitic Stenosis.—Dr. A. A. Kanthack: Naked-eye Specimen of Pachydermia Laryngis.—Dr. Felix Semon: Two cases of Malignant Disease of the Larynx cured by Thyrotomy and Excision of the Neoplasms.—Dr. Scanes Spicer: A Laryngeal Neoplasm of apparently sudden origin.—Mr. W. R. H. Stewart: Unilateral Laryngitis.—Mr. C. J. Symonds: (1) Syphilitic Stenosis of Larynx wearing a Tracheotomy Tube; (2) Pachydermia Laryngis; (3) Lunated Fold of Mucous Membrane (undescribed?) Protecting the Middle Meatus.—Dr. H. Tilley: (1) Paralysis of Left Vocal Cord; (2) Advanced Tubercular Disease of Larynx.

Hunterian Society.—At 8.30 p.m. Pathological Evening. Dr. William Ettles: Cast of a case of Monoculous Fœtus or Cyclops.—Dr. Turner: Dilatation of Stomach.—Dr. Manson: (1) Sputum from a case of Pulmonary Distomiasis; (2) Malaria Parasite.—Dr. James Galloway: (1) A Peculiar Form of Secondary Growth in Carcinoma; (2) Extra-uterine Fœtation.—Mr. Charters J. Symonds: (1) Extra-uterine Fœtation; (2) Fibroid of Uterus (both removed by hysterectomy); (3) Vermiformix Appendix containing a Pin.

West London Hospital (Hammersmith).—At 5 p.m., Mr. Percy Dunn: Foreign Bodies in the Eye and Ophthalmic Cases. (Post-Graduate Course.)

Thursday, March 15th.

Harveian Society.—At 8.30 p.m., Discussion on Influenza, to be opened by Dr. Samuel West.

Society of Anæsthetists (20 Hanover Square).—At 8.30 p.m., Mr. Richard Gill: The Relation of the Pupil to Anæsthesia.

Friday, March 16th.

Royal College of Surgeons, England.—At 5 p.m., Prof. Chas. Stewart's Lectures on The Physiological Series of Comparative Anatomy in the Museum.

Vacancies.

Bethlem Hospital.—Two Resident Clinical Assistants. Apartments, rations, and attendance provided. Applications to the Clerk, Bridewell Hospital, New Bridge Street. (See advert.)

Bolton Infirmary and Dispensary.—Junior House Surgeon. Salary £80 per annum, with furnished apartments, board, and attendance. Applications and testimonials to the Hon. Sec. not later than March 20th.

Carmarthen Joint Counties' Lunatic Asylum.—Medical Superintendent. Salary £500 per annum, with unfurnisded house, washing, &c. Applications and testimonials to the Clerk to the Visitors by 24th March.

County Carlow Infirmary.—Surgeon. Salary £94 per annum. Applications to the Secretary before March 20th. (See advert.)

Metropolitan Asylums Board.—First Assistant Medical Officer for the Darenth Schools for Imbeciles. Salary £160, rising to £200, with board, apartments, and washing. (See advert.)

Norfolk County Asylum, Thorpe, Norwich.—Junior Assistant Medical Officer. Salary £110 per annum, increasing to £150, with board, lodging, and washing. Applications and testimonials to the Medical Superintendent by March 20th.

Appointments

Collier, H., M.D.Brux., L.R.C.P.Lond. and Edin., M.R.C.S.Eng., Medical Officer to the Great Yarmouth Workhouse.

Lack, H. L., M.B., F.R.C.S., Demonstrator in Surgery to King's College, London.

Lake, W., D.P.H.Camb., M.R.C.S., Medical Officer to the Guildford, Godalming, and Woking Isolation Hospital.

McRitchie, D., M.B., C.M.Aberd., a Medical Officer to the Hunts County Hospital.

Modlin, J. G., M.B., B.S.Durh., Medical Officer for the Monkwearmouth East Sanitary District of the Sunderland Union.

Moore, E. C., M.B., C.M.Edin., Surgeon to the Edinburgh Ear and Throat Dispensary.

O'Sullivan, M., M.B., B.Ch.Irel., Pathologist and Anæsthetist to the Children's Hospital, Temple Street, Dublin.

Preston, J. M. S., M.B., C.M.Edin., Medical Officer for the No. 3 Sanitary District of the Manchester Union.

Rook, A. E., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Workhouse of the Eastbourne Union.

Rubra, H. H., M.R.C.S., L.R.C.P., Assistant House Surgeon to the Cumberland Infirmary, Carlisle.

Tattersall, C. H., L.R.C.P.Lond., M.R.C.S., L.S.Sc.Durh., Medical Officer for Oldham.

Births.

Canton.—March 3rd, at Headford Place, Kells, the wife of Thomas Canton, M.R.C.P.I., L.M., L.R.C.S.I., of a son.

Parry-Jones.—March 6th, at High Street, Alfreton, Derbyshire, the wife of Maurice Parry-Jones, M.D., of a daughter.

Deaths.

Anwyl.—March 2nd, at Rio de Janeiro, of yellow fever, J. Norman Anwyl, M.R.C.S., L.R.C.P.Lond., eldest son of Mr. J. Warrin Anwyl, Abingdon.

Barton.—March 10th, at Mentone, France, John Kellock Barton, M.D., F.R.C.S.I., of 6 Merrion Square, Dublin.

Burns.—March 10th, at Borstal Villa, Rochester, J. J. Douglas Burns, R.N., M.D., M.R.C.P., J.P., aged 78.

Davys.—March 11th, at 19 Lower Mount Street, Dublin, Frank J. Davys, M.D., F.R.C.S.I., J.P., and Coroner, of Cremona, Swords, Co. Dublin.

Dickinson.—Feb. 28th, Charles Dickinson, Surgeon R.N., aged 31.

Griffiths.—March 10th, at 2 Hatherley Villas, Cheltenham, Cecil Neil Griffiths, M.R.C.S.Eng., L.R.C.P.Edin., aged 41.

Macpherson.—March 1st, at 251 Bath Street, Glasgow, Robert Macpherson, M.D., aged 39.

Morris.—March 1st, of paralysis, Dr. de Courcy Morris, late of Shepherd's Bush, aged 47.

Mungle.—March 8th, at 18 Scotland Street, Edinburgh, Robt. Mungle Staff Surgeon R.N., aged 68.

Witherby.—March 3rd, W. Henry Witherby, M.A.Oxon., M.D.Dub.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CVIII. WEDNESDAY, MARCH 21, 1894. No. 12.

Original Communications.

A GYNÆCOLOGICAL QUESTION OF IMPORTANCE IN FORENSIC MEDICINE RELATING TO THE HYMEN.

By H. MACNAUGHTON-JONES, M.D., M.Ch., M.A.O. (Hon. Causa), F.R.C.S.I. & E.

IT may not be without some sense of relief that you consent to divert your attention for a few brief moments from the discussion of pathological specimens, and cases illustrative of phenomenal manipulative skill, to consider a medico-ethical question of special gynæcological interest. It cannot be denied that there are many medico-legal subjects of importance to the gynæcologist which might afford opportunity for valuable discussion. Is it not true that the gravest issues, even those of life and death, liberty, loss of character and reputation, more serious to some than the forfeiture of life itself, frequently hang upon the evidence of the gynæcologist? And is it not equally true that this evidence is occasionally founded upon a most superficial knowledge and cursory examination, whether clinical or pathological? This is the more sad when we realise the forces frequently arrayed against the accused. There are the bias of expert partisanship, the bias of the policeman and the detective service, the bias of the advocate and the bench, and the hydra-headed triplet of custom, red tapism, and legal precedent. Add to these antagonistic forces the exaggerrated and mendacious reports, circulated through the modern coster curse of cheap literary wares offered to a curious or prurient public, which involve, in all their atmosphere of mystery or tragedy, that damnable half-truth which gossip or malignity so readily converts into the whole lie. The effigy of the victim is now-a-days hoarded with indecent haste long before the law steps in to secure him in its clutches.

There is, perhaps, no calling so exposed to such intentional, or unintentional, misrepresentations as that of medicine. This must ever be so, from the numberless delicate and intricate relationships we hold to patients, their relatives, and friends; from the regrettable, but natural, intra-professional animosities and jealousies of rivals in competition, and from the many unavoidable accidents and errors of our professional lives. Hence it is to our advantage and interest as a body that the strongest safeguards that scientific medicine can secure should be within the reach of every incriminated person, and that we should make the *onus probandi* as heavy as possible for the accusers. While we by no means desire to shield the guilty, above all things we should strive to protect the innocent.

How constantly have we not read of collateral facts or circumstances having been strained, from the detective point of view, to the detriment of a prisoner, which to us, regarding them from the closer and clearer light of our personal medical experience, might be easily explained. The possession, position, or condition of a certain uterine appliance, the length of time and the circumstances under which a practitioner is with a patient, casual expressions carelessly let fall in the presence of some third party, who may either wilfully pervert, or unwittingly distort them, may be, and I fear, often have been, the cause of terrible suffering to the innocent man or woman.

But what I more especially here desire to notice is that confident self-assurance which occasionally in the witness box asserts itself in matters that require considerable and special pathological experience to decide. This is more noticeable in cases of disputed chastity, asserted attempts at abortion, and, more particularly in cases where a verdict in a capital charge may hang on the pathological proofs of mechanical violence, or other means said to have been used to empty the uterus. To give an opinion of such vital moment to another on the post-mortem appearances present in the uterus a considerable time subsequent to the assumed interference, must frequently be a matter of extreme difficulty. To venture on one during life is still more hazardous. Therefore it is that all such evidence should come from or be fully supported by skilled pathological and clinical experts, and should itself be subjected to the closest scrutiny.

These remarks I make as merely introductory to the particular point to which I now wish very briefly to call your attention to, and I shall limit them to its discussion. The various abnormalities of the hymen from complete closure of the vaginal orifice to its absence, with or without other congenital peculiarities or malformations of the genital organs, it is unnecessary to refer to. That variety which has several times come under my notice, and to which I give the name of "*folding*," is the hymen of normal appearance and structure, but of a peculiarly yielding nature, readily admitting the passage of an ordinary vaginal dilator or a fair-sized speculum in the passing of which it folds back against the vaginal wall, and returns quite intact on the withdrawal of the instrument. Though, of course, aware that the fact of an uninjured hymen, even to the point of delivery near the expiration of the full time of pregnancy, has been recorded, I did not at the time I determined to read this paper recollect that a few years since Professor Kinkead, of Galway, had made a valuable communication to the Academy of Medicine in Ireland, drawing special attention to the question of virginity in relation to unruptured hymen, until I was recently looking over the literature of the subject.

Before referring to a few of the cases instanced by him, I wish briefly to sketch the outlines of certain circumstances that may occur, in which this question of "folding" hymen is of vital moment. For particular and obvious reasons, I do not enter into the details of special cases which have occurred within my own knowledge, but I will place before you a few contingencies exactly parallel to such cases, one of which has more specially prompted the submission of this communication.

I.—A patient is brought for examination who has been recently married. A coolness has arisen immediately after marriage, owing to some difficulty having occurred in intercourse, which she ascribes to ineffectual efforts on the part of her husband. But, contra, he alleges that she has resisted, and feigned such great pain at the time that he had to desist. This coolness is accentuated by a suspicion of previous impurity on the part of the woman. Upon examination, the hymen is found complete, but of the folding type. An opinion has previously been given that the woman was intact. Subsequently, disclosures proved that she had lived irregularly, and had aborted previous to her marriage.

II.—A patient wishes to establish a charge of impotence against her husband. She has already been examined with this object, and pronounced intact. It is ascertained that there have been only a few occasions on which sexual intercourse can have occurred within a given number of months. She strongly resists internal examination, lest the hymeneal proof of her virginity should be destroyed. Looking at the hymen, it is found uninjured and normal in appearance. Casually, during examination, a slight supra-pubic enlargement is discovered. This arouses suspicion, which the appearance of the mammæ confirms. A vaginal examination is carefully made, and a perfectly yielding hymen is found of the nature described. Though told that she is pregnant, the patient persists in the denial of cohabitation having taken place, even to the point of endeavouring to produce medical evidence of her chastity in a case for nullity of marriage. She is, however, confined of a child at full time some six months subsequently.

III.—A most serious charge is preferred, which is in part rebutted by exculpatory evidence on oath that a man has had intercourse with a young girl, extending over a considerable period of time. The case is one in which the gravest issues are at stake.

The girl's cause is subsequently taken up by powerful friends, and she is submitted to medical examination. The hymen is found complete, and upon this fact, medical opinions are elicited that it would have been impossible, or at least improbable, that sexual intercourse could have been continued over such a length of time as that stated. She is brought for an expert judgment on this point.

The hymen is found as already described, but on a digital examination being made it completely yields and folds back.

Ultimately, without any force or difficulty, a fair sized conical speculum is passed, and also a comparatively large glass vaginal dilator, without the least injury. The opinion was given that frequent coition, partial or complete, was quite feasible under the conditions, but that *the chastity of the girl was not impunged.*

Nevertheless, legal pressure only stopping at the point of dragging an unwilling and hostile medical witness into court is unsuccessfully exercised to force an opinion that it was not possible under these conditions that repeated copulation could have happened.

These three examples are sufficient for my purpose. In them we have the following issues involved :—

In Case 1.—The impotence of the husband, and the anti-marital chastity of the wife, as bearing on the question of nullity of marriage or separation.

In Case 2.—The impotence of the husband and the problematical doubt raised as to the parentage of the child.

In Case 3.—The perjury of the man and the chastity of the woman.

It is in cases of asserted attempt at rape, in which the previous chastity of the assaulted woman—or the one assumed to have been assaulted—is in dispute, that this question of a folded hymen may arise. An examination of the woman having been ordered to determine the doubt raised as to her former history, and an intact hymen being found, the evidence of any previous liasons might be rebutted by the medical evidence as to the condition of the hymen.

Quite recently I had under my charge a married woman whom I treated for some endocervicitis and erosion of the cervix, in whom I had no trouble whatever in passing the speculum I show you, and in whom there had never been the least difficulty in coition though she had not conceived. The hymen was never injured by the passage of the instrument, the membrane simply folded back in tubular form as the speculum was pushed into the vagina, and returned again into its natural position on its removal.

I find that in a discussion which took place on Dr. Kinkead's paper, amongst other testimony to the possibility of frequent sexual intercourse occurring with unruptured hymen, Dr. Lombe Atthill said that he "was perfectly satisfied that not even a slight cracking of the hymen followed necessarily from intercourse. In certain cases the hymen yielded, like a piece of indiarubber to gentle pressure, without cracking, and afterwards regained its previous condition, and was only cracked by parturition." At the same discussion a fact that I have myself noticed was adverted to, viz., that a pessary may be introduced into the vagina without rupture of the hymen, nor must it be forgotten that intercourse has taken place in certain cases per urethram, in which there has been no injury to the hymen. There is another matter that indirectly bears on this subject. In relation to the question of chastity the possibility of coition having frequently occurred without any further penetration than that carried inside the lips of the vulva is a matter of moment.

Two of Professor Kinkead's cases I will quote in full, as they bear specially upon the possibility of vulval intercourse continuing for a considerable time without any penetration.

Case 1.—A prostitute, suffering from syphilis, with condylomata, also sores on, and discharge from, the vulva.

"Seduced at 17, she had passed some time as the mistress of her seducer, after which she lived for two years as a soldiers' prostitute. Returned to Galway her time was occupied between prostitution and prison life. On examination Dr. Kinkead found no enlargement of the nymphæ, no laceration of the fourchette, and there was a well developed, unruptured hymen, the edges sharp and perfect without a single tear. The cause of the non-penetration seemed to him to be that the arch of the pubes was of the masculine type—angular—and the vulva placed more back than usual. In treating a sharp attack of gonorrhœal vaginitis, a small-sized Ferguson's speculum was passed, and the hymen tore without any extra force."

There is the possibility of such incomplete coition happening frequently in a case in which the hymen is of the yielding or folding kind.

Case 2.—Patient consulted for amennorrhœa. The hymen was perfect, its edges sharp and untorn; in shape, position, and consistency, it was normal, showing no evidence of pregnancy. The fundus uteri could be felt over the pubes. Finally, the patient confessed that she had had intercourse three and a half months previously, just before the menstrual period was due.

Of the other two instances Professor Kinkead cites, in one, labour was delayed by the hymen, the edges of which were thin and white, the remainder "red." He lacerated the hymen without difficulty with his finger, and delivered with forceps. In the second the hymen was intact in a woman, æt. 40, in her first labour, but it apparently was placed abnormally. There is a form of hymen which has been described by Skene, of New York, as the "hymen firmbriatus," fringed like the Fallopian tubes. Such irregularities might be mistaken for injury, and it is important to remember, as has been shown, that the carunculæ are formed only by child bearing, and not by simple laceration. It is, therefore, all important to recollect that mere vulval intercourse is commonly occurring, and that such partial cohabitation leaves no proof behind that it has been indulged in. The law does not define in what "penetration" consists. The numerous cases which have been published, and instances of those which have occurred within the personal experience of most of us, of pregnancy happening with an almost imperforate hymen, are but examples of conception following these half completed acts of coition.

I think I have said enough to elicit from this society an expression of opinion on this matter, in addition to that given in the Academy of Medicine in Ireland, which may be of service in disputed cases arising in the future.

The wider and more explicit the knowledge that this folding condition of uninjured hymen may exist, though the woman has for a considerable time had sexual intercourse, and the more exceptional or rare the class of case in which this may occur that is placed on record, the better. For it is just these out of the way occurrences arising suddenly without warning, that may put men off their guard in giving an opinion, upon which, for themselves and others, so much may depend.

The few cases I have formulated demonstrate the complicated association of circumstances which may group themselves round the solution of what many may consider so simple a proposition to establish as the chastity of a woman. I apologise for the time I have occupied in bringing a subject in which there is nothing very novel before you, on the mere ground of its importance to the public and our profession.

◆

THE ELECTRICAL TREATMENT OF INFANTILE PARALYSIS. (a)

By H. LEWIS JONES, M.D. Cantab., M.R.C.P.
Medical Officer in Charge of the Electrical Department, St. Bartholomew's Hospital.

The points which I propose to bring before the notice of the Society to-night are some which have cropped up from time to time in the past three years of work in the Electrical Department of St. Bartholomew's Hospital, where I have had opportunities of continuously watching the progress of many cases of infantile paralysis for long periods of time.

The long lasting paralysis and atrophy which this disease so often leaves behind it tends very greatly to discourage one's efforts of treatment, and indeed it is only by watching and treating patients for months or years that their slow and gradual improvement becomes perceptible, as the result of an electrical testing which has shown seriously impaired reactions. Many people have been told that their children were beyond reach of treatment in the more severe cases. It is quite certain, though, that prolonged electrical treatment will do much good to nearly all cases of infantile paralysis, provided that the children are young and not more than two or three years have gone by since the incidence of the disease. Even after that lapse of time something may be done.

In an electrical department cases of infantile paralysis are apt to collect together in great numbers, and indeed they may become so numerous as almost to monopolise the whole energies of the department. Soon after commencing the electrical treatment of this disease it occurred to me one day that the numbers in attendance were becoming unmanageable, and that it might perhaps be as well to discharge some of the most unpromising cases, but I found that the mothers of the children were unanimous in declaring that the treatment was doing good, and that they all begged to be allowed to continue attending longer. As this was encouraging, I thought it would be profitable and interesting to watch the cases more closely and for a longer period, in order to see whether some satisfactory progress might not be gained. Since then I have been able to recognise the improvement, and to discharge very considerably improved a fair number of children who came under treatment in a more or less crippled condition.

There is a formula in which the prognosis of infantile paralysis has been commonly summed up. It is as follows: If the ganglion cells supplying the muscle are destroyed recovery must be impossible, and if the cells are not destroyed treatment is unnecessary, because the patients will get well of their own accord. This formula, I am sure, has done a great deal of harm, for it is widely accepted because it saves such a lot of trouble. But it starts from the assumption that the disease must either destroy all the motor cells of a muscle or else must leave them all uninjured, and this assumption is certainly not correct. On the contrary, the damage to the motor cells may be of any degree of severity or of any extent, and the paralysis may vary between slight weakness and complete loss of all motor power.

It is, I think, reasonable to suppose that a lesion in the motor tract of the cord may destroy some of the nerve cells of the nucleus of origin of a muscle, while others in the same nucleus may escape, and this might especially be the case if the nucleus of origin is an extensive one. Although the nuclei in the anterior cornua have not yet been mapped out into groups corresponding with the muscles they supply, yet there is evidence to support the view that many of these centres extend for an appreciable distance longitudinally in the cord. Dr. Sherrington, than whom there can be no better authority on this point, in an exhaustive paper on the lumbo-sacral plexus, based on experimental researches in monkeys and other animals clearly takes the view that some at least of the nuclei of origin of muscles in the anterior cornua may occupy an area of considerable extent, and in the plate which accompanies his paper in vol. xiii of the *Journal of Physiology* he represents the nerve supply to many of the muscles of the leg as arising from the cord at two or three separate levels.

If this be so in the human subject one can readily understand how a muscle might be partly crippled by poliomyelitis and yet retain a more or less complete degree of voluntary power through the support of such of its ganglion cells as might happen to survive. There is also the possibility of neighbouring cells taking up the work of those destroyed. The object of electrical treatment would then be to stimulate and develope any surviving fibres, and if possible to make them numerous enough and strong enough to form an useful muscle.

Duchenne, long ago pointed out that a muscle crippled by infantile paralysis may still contain a few living functional muscle fibres, and that these may easily be overlooked in an ordinary electrical examination of the muscle, but that they may be successfully cultivated by persevering treatment. There is no doubt that cases admitting of similar interpretation do occur, for example, I have seen a quite respectable sized mass of calf-muscle develope in a limb which for two years at least had shown no trace of electrical reaction of any sort in that region, and the same in other muscles, notably in a deltoid muscle which, after remaining for nearly three years completely atrophied as the remnant of an extensive paralysis of the upper arm, is now beginning to grow, and to show faint contractions of normal quality to the induction coil.

A muscle which is greatly atrophied, and in large part the seat of fatty degeneration, may still contain a fair number of active muscle fibres scattered in it, and these may remain in a dormant state for several years and yet be capable of great development if eventually they come under electrical treatment. Duchenne has related several cases of this sort, where treatment commenced as late as four years after the onset of the disease gave most favourable results.

Through the kindness of Mr. Langton I have had an opportunity of testing and dissecting the muscles in an amputated leg the seat of severe infantile paralysis of old standing. The age of the patient was 20 years, and the limb had been diseased from childhood. The muscles of the leg were all extremely atrophied, degenerated, and fatty; in fact, the calf was almost indistinguishable from adipose tissue, but still contained a sufficient number of normal muscle fibres to make it contract fairly briskly to the induction coil current. The other muscles of the limb, though in a state of advanced atrophy, all contained fibres which were able to respond either to the induction coil or to the galvanic current.

(a) Paper read before the Medical Society of London, March 5th, 1894.

The majority of the cases of infantile paralysis with which I have had to do are those with paralysis of the leg muscles, and in many of them a year or two years or more has elapsed since the incidence of the disease. Apparently the lower limbs are much more commonly affected than the upper, but this may be partly accounted for by the sources from which the electrical department at St. Bartholomew's Hospital is supplied, for a large number of cases are sent over by Mr. Walsham from the Orthopædic Department, having been brought there in the first instance because of some lameness. Among the poor it often happens that the paralysis is overlooked or neglected until the time has come for the child to begin to walk, and then, or even later, an effort is made by the parents and the child is brought for medical advice. I mention this in order to show that these cases have, many of them, been left to improve spontaneously before coming under treatment, and in fact that they are cases of old standing, who have undergone what is called expectant treatment without recovery. The material then is not of the most favourable kind, and some of them are in a sorry plight, but all the cases that come, however hopeless they may look, are put under treatment, and all improve, some only a little, others very much.

Among the cases two different types exist. In one the muscles are thin, but they present reactions which though weak, are normal in quality both to the induction coil and to the constant battery. In the other group the muscles are paralysed, atrophied, and show only a reaction of degeneration, or even no reactions at all.

It cannot fairly be said of the first group that they will recover spontaneously, their very presence in the department shows that they have failed to do so. Under treatment they usually begin to progress from the first and as a rule do very well, but even so their improvement is often a gradual one, requiring treatment for months. When these cases have ceased attending for a time and they are again brought back, the history is usually that the progress of the muscles went on for a time, and then ceased, therefore they are brought again for further treatment; others do better and recover completely from the first, but the affected limb commonly remains rather thinner and rather weaker than its fellow.

I do not wish to imply that no muscle paralysed by poliomyelitis recovers spontaneously, it is certain that many do so recover but rather that there are many cases which remain in a state of very imperfect recovery, even though their electrical reactions are normal, and that these derive immediate benefit from systematic electrical treatment.

With cases of the second class, namely those with great atrophy, paralysis and the reaction of degeneration it is also too sweeping a statement to say that they are incurable, and that electricity can do nothing for them. Electrical reactions do return in muscles which before showed no signs of contraction, and this I have seen a fair number of times, in particular I would mention a patient brought to the hospital at the age of 3, with a history of paralysis having come on at the age of 4½ months. She had been an in-patient for four months at Queen's Square, and while there recovered power in her arms and back, which had been powerless. Treatment commenced in June, 1891. No reactions then in any muscles of either leg, extreme wasting, tendency to talipes equinus in left foot. Patient quite unable to stand. The improvement has been very slow, the attendance very regular; at present her legs show reactions to the induction coil in very nearly all the muscles on both sides, and she can walk, though in a rather awkward manner. This is due to the state of one quadriceps extensor muscle, which continues very thin and weak. This child, although still very feeble in her legs, has made and is still making progress, and is a clear instance of the return of voluntary power and normal electrical reactions in muscles which at one time seemed to have fallen into the last degree of atrophy and paralysis.

Two similar cases of which I have notes are the following:—

F. P., æt. 5, paralysis for four years, return of normal reactions after six weeks treatment.

C. T, æt. 11, paralysis for eight years, return of normal reactions after eighteen months treatment.

The routine treatment adopted at St. Bartholomew's with the infantile paralysis cases is as follows:—At the first visit the muscles are tested, the girth of the affected limb measured, and the voluntary power of the paralysed muscles ascertained, and any faulty attitude of the limb noted. The mother is then told that the child must be brought twice a week to the department for six months, at least, for electrical treatment, and she is further told to bathe and manipulate and rub the affected limbs every night for a quarter of an hour in hot water. If irons or other orthopædic appliances are worn the child is to be encouraged to exercise its limbs without them for a little time every night before the evening bath. By impressing upon the mothers the need for patience and perseverance, one is able to ensure their hearty co-operation, and this is the most important factor of all. The electrical treatment of the children is for the most part carried out at the hospital by the mothers themselves, who are shown how to use the electrodes, and quickly learn what is required. A very fair proportion of the total cases settle down into regular attendance. Those who fall away do so usually in the earlier months of treatment, those who remain remain long.

The first signs of improvement are a better circulation in the affected parts, and disappearance of chilblains and sores, and a gradual gain of voluntary power.

The return of electrical reactions comes later, and it is common when all contractility has been lost for the normal reaction to the induction coil to return without an intermediate stage of contraction to galvanism only. This may perhaps be explained by supposing that the few latent normal fibres in the wasted muscle have begun to grow and gain sufficient strength to produce a visible contraction.

The apparatus used:—Both the induction coil and the constant current battery are employed for the electrical treatment. Custom has selected the constant current for the treatment of muscles showing the reaction of degeneration, reserving the induction coil for the less severe cases in which the muscles retain the power of contraction to the currents of the induction coil. This choice of current is probably based on theoretical grounds. It is true that a muscle showing the reaction of degeneration will contract to the constant current only, and in so far as the contraction of the muscle is a good thing for the muscle, the constant current may be better than that of the induction coil; but it is by no means certain that the amount of benefit can be measured by the amount of contraction set up in the muscle. A muscle which is completely cut off from its nucleus of origin will continue to degenerate and waste, however persistently it be made to contract by treatment with the constant current. This matter of the relative advantages or virtues of constant and interrupted current dates from a long way back. Each has been warmly advocated by its partisans to the exclusion of the other since the days of Duchenne and of Remak.

But in paralysis any form of electrical application is of value simply as a most convenient way of stimulating the activity of the living tissues of the part under treatment, and, as a matter of fact, even with the constant current of a battery the stimulation is chiefly obtained when the current is made to vary by interruptions or reversals, or by movements of the electrode over the surface.

The recent investigations of Messrs. Gautier and Larat seem to show clearly that varying currents have a greater stimulating action on the tissues than steady currents, and that the former promote the metabolic activity of the living cells to a very much greater extent than steady currents do, and in practice, I have found that the interrupted currents of the induction coil have quite as high a value in the treatment of infantile paralysis as the constant current of a battery.

When the treatment has to be put into the hands of a nurse the induction coil is the best, because it is more easily managed and kept in order, and the vibrator with its buzzing sound serves to show that the apparatus is working, and the strength of the current can be readily gauged by feeling it.

Whenever children are to be treated by electricity great care must be taken not to frighten them by sudden shocks, the current used must never be so strong as to alarm them or make them cry, and it is important that the contact breaker of the coil shall work very smoothly and evenly. Many coils are defective in the matter of contact breaker ; until lately there has been little attention given to it, and any sort of vibrating spring is thought good enough, but there is all the difference in the world between a good and a bad one. The difficult problem of testing a child's muscles without making it cry becomes much easier with a good coil, and a smoothly acting contact breaker working about forty or fifty times a second. Of all the coils I have tried those of Gaiffe, of Paris, seem to me to be the best.

It is perhaps a little premature to discuss the value of the electrical supply from the house-lighting mains, as I have not yet had opportunities of trying it upon cases of infantile paralysis, but from general considerations of the quality of current on the alternating system of supply I am disposed to think that that form of current properly applied through a transformer should be of distinct value in the treatment of infantile paralysis.

When the lower limbs are the seat of the paralysis an improvised electric bath is an excellent method. An ordinary wooden tub or earthenware foot-bath filled with warm water is taken, the electrodes in the form of plates of metal are suspended at the two ends, and the child dressed in a short waistcoat is put into the bath in a sitting position. The current is very well borne in this way, and the whole extent of the paralysed parts comes simultaneously under treatment. This plan can easily be carried out at home by the nurse or mother of the child. The strength of the current is gauged by putting the hands into the tub, one at each end. This plan requires no special knowledge of anatomy, it is efficient and likely to be persevered in, and this question of perseverance over long periods of time is the key to success. Even if only one of the lower limbs be affected, there is no reason why the bath should not be used, and if the sound leg be flexed and drawn up most of the electrical current can be diverted into the affected one.

In conclusion, I give as a summary of the position : It is important in every case of infantile paralysis which has lasted over four weeks to try electrical treatment, continuing it for six months or a year.

It is the exception for a muscle to be so completely destroyed by poliomyelitis as to have no functional fibres left, and great development of these remaining fibres may be gained by persevering stimulation of them.

Where the electrical reactions are reduced to the very lowest flicker, or even entirely abolished, some improvement may be hoped for.

Where the electrical reactions are not altered in quality, it is not good practice to leave the case to take care of itself. Electricity acts only as a stimulating treatment, but it is superior to any mechanical stimulation by rubbing or massage. It may advantageously be combined with these. The form of electrical stimulation to be employed is less important than the need for perseverance.

The induction coil with or without the bath is quite easily arranged for use by the mother or nurse of the patient.

◆

NOTES ON

A CASE OF TUBAL GESTATION,

OPERATED ON TWICE SUCCESSFULLY IN EIGHTEEN MONTHS.

By R. CREWDSON BENINGTON, M.D.
(Newcastle-on-Tyne).
Vice-President of the British Gynæcological Society.

Mrs. B—, æt. 28, married five years, one child four years ago, with the exception of the following she has had perfectly good health.

Before marriage and since, she has had a little leucorrhœa at times, but at no time much or sufficient to call for advice. Except during her pregnancies she has always been regular, no dysmenorrhœa nor excessive loss, three weeks interval. She had a very quick labour (two hours), had puerperal peritonitis after, and is said to have been very ill for a fortnight. *Two years after this, in* 1890, *when in America, she missed one period, then it came on accompanied with great pain. She was kept in bed* 10 *days under the influence of morphia, and was said to be suffering from inflammation of the bowels.*

On May 7th, 1892, I was called to see her at 8 p.m. She had been perfectly well up to 7.30 p m. She had last menstruated on March 22nd. For the last two or three days she had had a slightly coloured discharge from the vagina.

I found her suffering from great abdominal pain and tenderness. The abdomen was resonant in front and in the loins. *Per Vaginam*—An ill-defined swelling was felt in the left fornix which was exquisitely tender. Cervix showed none of the characteristic signs of pregnancy. Nipples and areolar were rather dark, had had no morning sickness. A 9 p.m., vomiting set in and symptoms of collapse gradually followed. I had her taken to a private hospital as quickly as possible and assisted by Mr. Morison I opened the abdomen at 11.30 p.m. By this time there were evident signs of a large quantity of fluid in the peritoneal cavity and the collapse was so great that we feared she would die on the table.

On opening the abdomen a large quantity of blood escaped, the left tube and ovary were easily found and removed, the peritoneal cavity cleansed as carefully as her condition allowed, and she was quickly got to bed. The drainage tube was removed on the fourth day. She made an uninterrupted recovery and returned home from the hospital on the 15th day.

From this time to October 9th, 1893, she continued in good health, on this day she sent for me. She had not menstruated for five weeks and now had some ill-defined pain in the lower abdomen. Vaginal examination revealed nothing. During the next three weeks she was never well, she had pain constantly, some days worse than others, and twice so badly as to necessitate several days in bed. She also had a slightly coloured discharge at intervals from the vagina. During this period there was palpable enlargement of the uterus, the cervix softened and the os became patulous. There was some milk in the breasts. I was extremely doubtful about her condition but inclined to the opinion that it was a normal pregnancy, with a tendency to miscarriage, and I attributed her pain to stretching of adhesions. Mr. Morison saw her with me and corroborated my opinion. She now complained of intense pain on defæcation, and I found a tender swelling behind the cervix which had not been there previously. It felt just like an enlarged tender ovary.

On November 8th, she had a sudden and severe attack of pain and I found the swelling behind the cervix very considerably enlarged. I again sought the assistance of Mr. Morison. There was so much tenderness that a thorough pelvic examination was impossible without an anæsthetic, and as the uterus could not be defined in front, the question arose as to whether the condition was not a retroverted pregnant uterus. We decided to give her an anæsthetic next day and to have everything ready for operation should it prove to be necessary. When under chloroform it was easy to define the enlarged uterus lying in front of the swelling in Douglas's pouch which was not so tense and more doughy to the touch than when felt previously. I therefore opened the abdomen and found a little blood free in the peritoneum. Owing to adhesions there was a little difficulty in reaching the tube, but on getting it to the surface it was evident what it was. Tube and ovary were removed. She made an exceptionally good recovery—tube removed in 30 hours—perfect union on 8th day; temperature during first week never rose to 100°; downstairs in three weeks, and has been out for a walk since.

In reviewing this case there are several points of interest. I have called the specimens exhibited ruptured tubal gestations, not in consequence of microscopical investigations but because of their clinical histories, and I think I am justified in having done so, but if the Society wishes for further corroboration, the specimens are at the disposal of a committee.

Assuming that they are ruptured tubal gestations, the first point of interest is, that the patient on whom I have twice operated for this condition possibly has had three tubal gestations, the history of her illness in America being suggestive of a similar event having occurred there, but in this instance it burst perhaps into the folds of the broad ligaments, and in the two last cases into the peritoneal cavity.

The second point of interest is the difficulty in diagnosis in the last illness, that is during the early stages before rupture. A man learns from his own failures, and on looking back at the case I am sure I exaggerated the difficulties and that they were more imaginative than real. I felt it hard to believe this patient had a second tubal gestation, and my scepticism was increased as the result of conversations I had with others on the subject, until the day before the operation. Had she been a new patient I do not think any difficulty in diagnosis would have presented itself to my mind.

With the experience of this case before me I am surprised that recurrences of this condition are not of more frequent occurrence than the literature indicates. If a tubal gestation arises from a diseased condition of the tubes it is unlikely that this will be unilateral, and this being so, it is a matter for consideration whether it is not the duty of the surgeon to remove both tubes and ovaries at the first operation and thus save the patient from a likelihood of requiring a second.

◆

Selected Prescriptions and Therapeutic Notes.

85.—For the Treatment of Acne:—

℞ Ichthyolis, ʒiss;
Etheris sulph., ʒiis;
Sp. vin. rect., ℥ss.

M. To be used externally. The application should be dabbed over the acne spots several times daily.

When there is much pustulation (*acné varioliforme*) the following ointment may be used:—

℞ Bismuthi subnitratis,
Hydrarg. ammoniati, } aa gr.xxx.
Ichthyolis,
Vaselini, ad ℥j.

M. For external use. Every evening, at bedtime, the acne pustules must be smeared with this ointment.

Von Hebra and H. Ullmann.

86. The Therapeutic use of Salophene:—

According to Siebel, Guttman, Koch, and others salophene possesses all the advantages, without the disadvantages, of salicylate of soda, and it is also superior to salol. It is prepared in the form of a white flocculent powder, has neither smell nor taste, and is of neutral reaction. In cold water it is insoluble, but is freely soluble in hot water, alcohol and ether. Its greatest advantage, however, appears to be that of relieving pain, as for example in cases of acute rheumatism. Also in neuralgia such as intercostal, dental, and other forms it acts as a powerful analgesic. In a case of tabes with much cephalalgia it acted like a charm in the relief of the latter symptom. The dose is from seven grains to half a drachm a day, taken either in the form of powders, pills, or in cachets.

87.—Spray in Simple Chronic Rhinitis:—

℞ Sodii boratis, gr. xv;
Sodii bicarbonatis, gr. xv;
Ol. eucalypti, ♏ij;
Thymolis, gr. j;
Mentholis, gr. ss;
Glycerini, ℥ss;
Aq., ad ℥j.

M. Add two teaspoonfuls to one ounce of warm water and use as a spray. Dr. Carseberry.

88. The Treatment of Psoriasis:—

The following local treatment of psoriasis is found to be very serviceable by Dr. Eddowes (London). The various patches are painted, after removal of the scales with soap and hot water, with a saturated solution of tincture of iodine, about once a week, and an ointment consisting of equal parts of the ung. sulphuris, and the ung. picis liquidum applied daily. Another useful application is the following:—

℞ Ung. picis liq., ʒiiss;
Acid salicylatis, gr. xxv;
Ung. lanolini, ad ℥j.

M.

◆

The late Dr. Roderick Macdonald, to whom we referred last week, was married to the great granddaughter of the Prime Minister, Mr. Perceval, who was assassinated in the Lobby of the House of Commons in 1812. Dr. Macdonald often mentioned the curious fact that he was his mother-in-law's medical attendant at the time of the birth of the infant who eventually became his wife. The latter died two years ago.

The new buildings of the Marylebone Dispensary, London, were formally opened on Friday last by the Duke and Duchess of Fife.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, February 23rd.

The President, Prof. Hamilton, in the Chair.

NEPHRECTOMY AND NEPHRORRHAPHY.

Mr. M'Ardle detailed a case in which he applied a supporting lumbar suture for the relief of floating kidney, and concluded his remarks in reference to this operation by saying:—I do not wish to be taken as advocating cortical incision or nephrorrhaphy for every floating kidney, nor do I hold with those who explore this organ every time they come across it enlarged or movable. Apart from the dangers arising from sepsis, and from the lethal phlebitis to which this operation exposes the patient, there are other, less widely recognised, but nevertheless very real, mishaps attendant on these procedures. One of these was well shown in a specimen demonstrated at the last Congress of German Surgeons by Barth. There was a necrotic centre found in the kidney owing to the occlusion of one of the arterial arches by the anchoring suture. A similar condition has been noted as the result of puncture. One of the large arteries is obstructed, hæmorrhagic infarction takes place, and ultimately necrosis. With these evidences of danger before my mind, and the frequent failures to afford relief after the most promising operations, I am far from being an advocate of indiscriminate tampering with the kidney. He next read the notes of a case in which he successfully removed a kidney with a large cystic (mono-locular) tumour, and in discussing the steps of the operation he said that the semilunar line was the best for reaching the renal vessels, which, he contended should be double ligatured and cut before attempting to enucleate the organ. Mr. M'Ardle advocated closure of the outer layer of the mesocolon, and complete suture of the abdominal wound. The mucous lining of the ureter should be snipped off, and the end rendered aseptic by corrosive sublimate solution. Partial removal of the kidney for malignant disease Mr. M'Ardle considered unjustifiable; and in reference to operations for sarcoma of the kidney in children, he was of opinion that surgeons should persist in their efforts, even though statistics showed that the percentage of recoveries was exceedingly small, as noted by Mr. Sutton in his recent book on Tumours. The communication concluded with a reference to the nephrectomies—12 in number—which Mr. M'Ardle found had been carried out in Ireland. Of these only one died from the effects of operation, one from co-existing pelvic cellulitis. Of the others, one died of phthisis, another of recurrent sarcoma, while eight remained perfectly healthy up to the present for periods varying from one to seven years.

Mr. Wheeler stated that he had performed nephrectomy in 10 cases, 2 of which ended fatally, while the others recovered. He considered that in most cases the anterior incision was the best, as it was the easiest, and obviated a danger which sometimes is present—namely, the risk of tearing the inferior vena cava. He recollected a case of horse-shoe kidney in which, *post-mortem*, both kidneys were found healthy, while the connecting band contained two calculi. In this case a lumbar incision would have been useless. With regard to the oozing of blood which sometimes occurred after removal of the kidney, he found that *hot* sponges were sometimes effectual in stopping it.

Sir William Stokes narrated the case of a woman with what was probably a large tuberculous abscess in the right kidney, on whom he had operated, making an anterior incision. He found dense adhesions all over the swelling, and these caused a great deal of trouble to break down. If he had adopted the lumbar incision it would have been impossible to remove the organ.

Mr. Tobin pointed out an accident which he had actually seen take place when the lumbar incision was made—namely, opening of the pleural sac and consequent collapse of one lung. He thought that in many cases it was well to make a counter opening for drainage in the loin when the anterior incision was the one by which the operation was performed.

Dr. A. L. Smith compared the treatment of the ureter to that of the Fallopian tube in cases of pyosalpinx. In these cases the mucous membrane was dissected off the interior of the tube for some distance and removed, and then the lips of the remaining coats inverted and the opening "topstitched." He recommended the adoption of a similar method for the ureter. He also said that clip forceps were not used nearly so much at present in abdominal operations as formerly. Vessels were now ligatured at once

Mr. Kendal Franks briefly narrated three cases on whom he had done this operation. The first was a case of multiple abscesses in a kidney from which he had a year previously removed a soft phosphatic calculus. The patient recovered and is now quite well. The operation was done in 1887. His second case—a girl affected with scrofulous renal disease—died. At the autopsy it was found that the other kidney was extensively diseased, and that there was extensive suppurative pelvic cellulitis. The third case was that of an enormous multiple cystic condition of the kidney. It would have been impossible to remove it except by an anterior incision on account of its size. The visceral peritoneum was stripped off the anterior surface of the kidney, the organ, which weighed two pounds was enucleated, and then the edges of the posterior layer of the peritoneum accurately sewed together. In this case he made a counter opening in the loin for drainage. Referring to Mr. M'Ardle's first case, he pointed out that many patients who were treated for indigestion, dyspepsia, and such like troubles, accompanied with pain relieved on lying down, really suffered from a movable kidney. In one case on which he operated he found that the kidney, by dragging on the duodenum, obliterated its lumen.

Mr. Thomson pointed out that it was sometimes very difficult to tell whether the second kidney was healthy even when you could feel it. He had assisted at an operation for renal calculus in which an anterior incision was made. The operator examined the other kidney, but at the post-mortem examination (for the patient died) calculous masses were also found in it. He thought it was wise in some cases to make a counter opening in the loin for drainage. He recommended inversion of the edges of the ureter, and closure by stitches. He thought that cases of sarcomatous kidneys in young children were better left alone. The result list of cases operated on was very dismal to read over.

Mr. M'Ardle, in replying, stated that he considered the anterior incision best, except where there was perirenal suppuration. A counter opening in the loin was advisable where there was any soiling of the lumbar tissues, and where free oozing of blood required tamponing. A moderate amount of blood, lodging in the site of the tumour, if strict asepsis was carried out, made very little matter. With regard to sarcomata in the kidney, he thought that if they even succeeded in saving four lives out of twenty-six they ought to operate.

The Section then adjourned.

◆

THE OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN.

Meeting held Thursday, March 8th.

The President, Dr. Argyll Robertson, in the Chair.

CASES OF ORBITAL GROWTH.

Dr. Hill Griffith (Manchester) related several interesting cases of orbital growths. The first case was the successful removal from the orbit of a man, æt. 35, of an encapsuled adeno-sarcoma, which was causing depression and downward displacement of the eye. The second was the removal of what after examination proved to be a hypertrophied lachrymal gland from the orbit of a young girl. When seen six years later a large irregular exostosis (?) filled up the space between the frontal arch and the eye. He suggested that probably the lachrymal glands had been pushed out of position by the slowly growing exostosis, and had been erroneously regarded as the cause of the trouble. The next case was one of symmetrical growths in similar positions in each eye respectively in a healthy young man, regarded as a case of acute hypertrophic inflammation of the lachrymal glands. Also a case of very slow and painless protrusion of the eyeball in a healthy young woman in whom a portion of the growth could be felt above and to the outer part of the orbit. Seventeen months after the first visit the tumour was removed, together with the orbital contents. The nature of the growth in this case was doubtful. He also referred to two cases of malignant growths in which the orbital contents were removed, followed in one case by death within twelve months from extension of the growth, and in the second case death from meningitis on the 24th day after the operation. In none of these cases was any measure beyond pressure required to arrest hæmorrhage, and he wished to protest against the use of the actual cautery for this purpose.

Mr. Juler said he could recall a case of symmetrical tumours of the orbit diagnosed to be sarcomata in a young woman. This progressed until there was loss of sensation on both sides with marked diminution of vision. The patient was the wife of a jockey who lived in Paris, and this suggested syphilis. As a matter of fact, on giving mercury all the symptoms cleared up and disappeared.

Mr. Adams Frost, Dr. Argyll Robertson, and others referred to similar cases in their own experience, *i.e.*, cases simulating sarcoma, but clearing up under specific treatment.

ADJOURNED DISCUSSION ON SCHOOL OPHTHALMIA.

Mr. Jonathan Hutchinson said his propositions were: first, that there was no essential difference between the form of ophthalmia which in workhouse schools led to granular lids, and that which at present obtained in several public schools; secondly, that the difference in the results was to be explained by the fact that in respect of the large public schools the patients had had the advantage of local and constitutional treatment from the first, but for which the disease would have run on to the same termination. The *onus probandi* rested with those who maintained that there were two distinct forms of epidemic contagious ophthalmia. He raised incidentally the question whether this form of ophthalmia was in any sense dependent upon defective sanitary conditions. Personally, he took the view that it spread by pure contagion, *i.e.*, from person to person, the sleeping and lavatory accommodation only affecting the spread in so far as personal contact was multiplied. Many of the certificates given by the family doctors were ridiculous, lads having been certified free from ophthalmia without their eyes having been even looked at. In years gone by, no less an authority than Erasmus Wilson had declared ringworm to be non-contagious, it being, according to him, merely a fatty degeneration of the hair, yet it had since been amply proved to be highly contagious. The same thing would, he believed, prove to be the case with this particular form of ophthalmia. Nearly all these cases could be cured if taken in time, but if neglected they would lapse into a chronic condition. Cases of the kind did not often come to the consulting rooms of specialists, the family practitioner generally being called upon to treat them.

The President suggested that discussion should be directed to the four following points:—1. Was there actually an increase in the proportion of cases of follicular conjunctivitis occurring in the large public schools? 2. Was there more than one form of this disease? 3. How the disease was spread, and 4. Whether a certificate of freedom should be required from lads before being allowed to return to school.

Mr. Juler thought it would be generally admitted that there had been a marked prevalence of ophthalmia last year, probably due in part to the exceptionally hot dry summer. He declined to admit, however, that it was granular lid ophthalmia. He objected to the term "school" ophthalmia on the ground that they might as well speak of "school" scarlet fever, or "school" measles, &c. He held that there were two distinct forms of the disease, a simple catarrhal ophthalmia which was met with both in an acute and in a chronic form, but which was always quite distinct from the form which terminated in granular lids. He admitted that it might be difficult in particular cases to decide forthwith which it was, but the effects of treatment would help them. The one was easily cured while the other was very intractable. In an outbreak in one school with 400 scholars, 100 of them developed ophthalmia. The usual treatment was applied and in a week or two most of them were well, only some 30 per cent. of the boys going on to a condition of granular ophthalmia. That led him to conclude that the epidemic was one of catarrhal ophthalmia, and that the children who subsequently developed granular ophthalmia were suffering from this granular or follicular condition before the beginning of the epidemic. He had seen boys from most of the public schools, but he had not seen a single case to which he would feel justified in applying the term granular ophthalmia. He urged that it was creating unnecessary anxiety to proclaim that granular ophthalmia was becoming more prevalent in the large public schools.

Mr. Doyne (Oxford) observed that last year there was an increase of eye troubles all over his district, but he had not so far come across any instances of trachoma. He hardly knew what was meant by follicular conjunctivitis. In the school referred to by Mr. Hutchinson there appeared to have been a case of trachoma attending the school unknown to the authorities, so that direct contagion might explain the former. That epidemic therefore would not justify a general alarm. He said he was unable to distinguish between the so-called follicular conjunctivitis and the ordinary muco-purulent form. He suggested that the condition was the result of an attack of the latter in a person whose lids were already in a follicular condition. Such follicles were often seen in eyes quite free from any trace of inflammation, but they at once become more prominent in the presence of an attack of conjunctivitis. He said he had fairly full notes of 12,000 cases of conjunctivitis and there were only 12 instances of trachoma, of which 11 were distinctly imported. One of the sufferers resided in a workhouse school without having determined any epidemic. Possibly the conditions in London were not the same as in the country. In the provinces at any rate the disease did not appear to be as virulently infectious as it was said to be in London.

Mr. Taylor (Norwich) said that until the end of 1893 he had not met with a single case of granular ophthalmia but during the last few months he had seen at least half-a-dozen. That looked as if the disease were very much on the increase. He thought that all schools should be inspected by their medical officers and suspicious cases isolated, and he suggested that this particular form of ophthalmia might advantageously be placed in the list of diseases to be notified.

Mr. Nelson (Belfast) said he had seen three of the cases under consideration. In one, the follicles were well marked in the lower lids and the patient had associated asthenopia dating from an attack of measles two years before. In the other two cases he had failed to find anything the matter with the eyes, but when they returned to school they were declared to be suffering from ophthalmia, and had been packed off home. It had occurred to him that the two sets of cases might get mixed up in consequence of erroneous diagnosis and that infection might thus take place, possibly the very same brush being used for the applications. Given the difficulty in the diagnosis of these cases he urged that it was idle to expect the general practitioner to diagnose them, and if he could not diagnose them he could evidently not be expected to treat them.

Mr. Anderson Critchett agreed that last year was marked by a prevalence of ophthalmia, but he did not think it was of the granular variety. In none of his cases had there been any relapse or any appearance of granular lids.

Mr. Hutchinson pointed out that the speaker had been treating these cases and it was therefore no matter for surprise that they should have recovered. It was the neglected cases that terminated in well marked granular condition.

Mr. Priestley Smith (Birmingham) observed that it was a pity to make use of terms such as follicular or granular without a qualification, because granules, *i.e.*, enlarged follicles, were met with in eyes which could not be distinguished from healthy eyes. He took a more hopeful view of these cases than Mr. Hutchinson. He did not think indeed, that this condition was contagious follicular disease at all. Many town dwellers developed tendencies to adenoid growths, a tendency which found expression elsewhere in follicular pharyngitis, &c. He pointed out that instillations of sterilised sulphate of atropine would sometimes determine all the appearances of follicular conjunctivitis, yet in such case it must be the result of a chemical irritant and not of contagion. He admitted that children presenting this condition of enlarged follicles were doubtless more liable than others to inflammatory affections of the eyes. He had seen more cases of conjunctivitis during the last six months than in six years previously, but he did not associate this with the disease known as trachoma.

Mr. McHardy thought that the freedom or otherwise of the children from eye disease must perforce be decided by the medical officer attached to the school.

Dr. Stephenson repudiated the idea that there were two contagious epidemic forms of follicular conjunctivitis. The result of a very extensive inquiry had been to lead him to conclude that the small transparent follicles in the lower lid were normal structures, ninety-four per cent. of the children at school showing them without any other indication of eye trouble. He dissented from the view that these follicular formations had anything to do with trachoma or even predisposed thereto, though in the presence of an intercurrent attack of muco-purulent ophthalmia, they might become very prominent, and give rise to the appearances which Mr. Hutchinson had described as trachoma.

Mr. Nettleship did not believe that there were two kinds of epidemic school ophthalmia. The tendency to overgrowth of adenoid tissue was markedly influenced by age and race, and hygienic conditions. It was most frequent in the young and in those who lived in ill-ventilated rooms, on a crowded area, or an inadequate diet. Children presenting these enlarged follicles, if attacked by any other form of ophthalmia, might in a certain, possibly a large, proportion of the cases, go on to granular lids. He urged, nevertheless, that they should be cautious in expressing any opinion that the tendency to granular lid was on the increase in the great public schools. It would probably be found that in the schools where these outbreaks had taken place, the conditions of environment had been such as to favour adenoid overgrowth. He did not think much good would result from the giving of certificates by private practitioners. The school medical officer must decide and isolate all suspicious cases.

Mr. Hutchinson concurred in the view that granulations in the lower lid had no pathological significance, the sandy lower lid having been the cause of many mistakes. In reference to the statement that the epidemic disease was nothing new, that it was a mild form of ophthalmia amenable to hygiene and tonics, he asked whether, the school authorities would have called in specialist after specialist if fresh air and tonics would have stayed its progress. Many of the boys who had been sent home came back worse than when they left. It was only in neglected cases that the disease ran on to trachoma, and this condition was not likely to be fulfilled in respect of the children of the well-to-do. He denied that purulent ophthalmia had anything to do with the formation of granular lids, and he declined to admit that the specific germ was derived from the genital mucous membrane. If so, the derivation must be very remote. He asked whether it was seriously disputed that a certain, possibly a small, proportion of these cases ran on to well-marked granular lids. As to that, he did not think there would be any serious difference of opinion. His own view was in favour of perfect isolation, with appropriate mild applications.

◆

BRITISH GYNÆCOLOGICAL SOCIETY.

Meeting held March 8th.

The President, Professor Thomas Savage, in the Chair.

SPECIMENS.

Mr. Bowreman Jessett read notes of three cases of vaginal hysterectomy, and showed the specimens. The first was a case of adenoid carcinoma. The second was a uterus studded with fibro-myomata. The operation was undertaken for the relief of severe pain. The third specimen was a large cauliflower epithelioma of the cervix. All three patients recovered.

Dr. Purcell read notes of three cases of vaginal hysterectomy, and of a case of supra-vaginal amputation of the cervix, and showed the specimens. All four operations were performed for malignant disease. The first two cases of hysterectomy, and the one of supra-vaginal amputation recovered; the other patient died of shock.

Dr. Parsons asked whether Mr. Jessett's first case, described as adenoid carcinoma, was of the same nature as the condition described by Dr. Williams as malignant adenoma. The symptoms of this disease, which is rare, are loss of flesh, and hæmorrhage; but there was no fœtid discharge, and pain was not constant. Some writers for instance, Pozzi, doubt its existence.

Dr. Napier related a case where he had performed supra-vaginal amputation of the cervix for malignant disease; he saw the patient a short time ago, six months after the operation, all the parts were in a satisfactory condition, with no trace of recurrence. While specimens were interesting, after histories were perhaps more so, and more important.

Dr. R. T. Smith thought it was a question whether hysterectomy was justifiable in Mr. Jessett's second case, he should have preferred to remove the appendages.

Dr. Lycett, commenting on one of the specimens which showed malignant disease of the fundus, spoke of the importance of thorough examination of the uterus in cases of menorrhagia.

Dr. Heywood Smith, who had seen Mr. Jessett's second case in consultation, said it was one in which oophorectomy would probably have failed to relive the pain. He would suggest, as a matter of ethics, that it was not advisable to give patients' names in full, as occurred in Dr. Purcell's paper.

Mr. O'Callaghan said that Mr. Jessett's excellent results had probably led him further than most operators would care to go; hysterectomy was a rather serious operation to undertake for a small myoma; myomectomy would as a rule suffice.

Dr. Christopher Martin showed a testicle removed from a "hermaphrodite." The patient, apparently a woman, came to the hospital complaining of amenorrhœa. She was æt. 20; the pubes was devoid of hair; the breasts were flat; clitoris and urethra were normal; vagina ¾ inch long; no uterus felt. In the left groin was a solid body, thought to be a hernia of the ovary. As it caused much pain, operation was advised. The body, when removed, proved to be a testicle. The patient had had an operation some time before for hernia of the other "ovary," probably this was also a testicle. An interesting feature of the case was that during the conception of this patient and of a "sister," who presented similar features, the father was temporarily insane. The children born before and after were healthy.

Dr. Macnaughton Jones read a paper on

A GYNÆCOLOGICAL QUESTION OF IMPORTANCE IN FORENSIC MEDICINE, RELATING TO THE HYMEN,

which will be found in another column. In the discussion that followed,

The President said he was sure all the Fellows would wish to thank Dr. Macnaughton Jones for his interesting and valuable paper, dwelling on circumstances which might occur in the practice of any of them.

Dr. Inglis Parsons said he had met with cases of the kind described in the paper as "folding in of the hymen," and it had occurred to him that such cases might lead to difficulties in a court of law. The converse difficulty was from absence of the hymen, for this might be a congenital condition, or it might be due to masturbation.

Dr. Heywood Smith suggested that it would have added to the interest of their discussion, if some of their legal friends had been asked to be present. The whole question turned on the multiform conditions of the hymen. From the forensic point of view, much depended on the legal definition of "penetration."

Dr. Barrett said he had met with a case of labour where the head was presenting, and only one aperture could be seen, which might have been either a widely dilated urethra, or a vagina with unruptured hymen.

Dr. Lycett remarked that most of these cases came into the hands of the police-surgeon rather than of the gynæcologist. He had often noted instances in which divergent opinions were given by medical experts, showing the great difficulties that sometimes lay in the way of a correct decision, and emphasising the need of caution in giving an opinion. In former days, when rape was a capital offence, and when an innocent valvo-vaginitis in children was not recognised, miscarriage of justice must have occurred with terrible results.

Dr. **Elder** described an illustrative case from his own experience, and dwelt on the responsibility involved in swearing away a man's character and liberty in a law court.

Dr. **Rasch** said that a decision must often rest on the elasticity or rigidity of the hymen. This factor also determined whether it was possible to make a digital examination without injuring the hymen. In most cases this could be easily done, the patient being told to make straining efforts.

Dr. **Macnaughton Jones**, in reply, thanked the Fellows for the interest they had shown in his paper. He wished to repudiate any intention of implying that the presence of a folding hymen impugned a women's chastity, but this repudiation was very different from convicting a man of perjury who affirmed that he had had intercourse in such a case. He thought it was always of use that such a society should express and place on record its opinions on a subject which might at any time come up in a law court, where the decision might gravely affect the life and even the liberty of a human being.

◆

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Meeting Held Tuesday, March 6th, 1894.

The President, Mr. **John Appleyard**, M.B., F.R.C.S., in the Chair.

"Pitting" in Small-pox.—Dr. **Logan** showed an arrangement of combined aspirating and injecting syringes communicating with a single needle, half curved and double-channelled. It is intended to minimise pitting in small-pox by evacuating the vesicular contents at an early stage and replacing them with antiseptic solutions.

Thyroid Extract in Warty Growths.—Dr. **Goyder** read a note on the use of thyroid material, and gave a case of extensive warty growths over the neck, shoulders, and breast of a young lady, which had been cured with about six weeks' treatment by the remedy.

Dr. Rabagliati, Honeyburn, Bell, and Parkinson discussed the subject.

Salpingo-Ovaritis.— Dr. **Rabagliati** showed specimens which had been preserved in ·001 mercuric iodide solution, and read a paper on salpingo-ovaritis. He gave two cases illustrating peracute and mild cases, both following miscarriage remotely.

INTESTINAL ANASTOMIS FOR OBSTRUCTION.

Mr. **Horrocks** read notes of a case in which a labouring man, æt. 61, came under treatment. After about six weeks' trouble with abdominal pain, there was distension of the belly, and coils of distended intestine could be seen and felt. Vomiting had come on after obstruction of the bowels, and obstruction was diagnosed, and owing to the late supervention of vomiting, probably in the large intestine; treatment by enema brought away formed motion and the patient improved for a time, diarrhœa even occurred. There was a recurrent attack of obstruction and vomiting, and laparotomy was performed in the right linea semilunaris, the colon was bound down at the hepatic flexure and two small nodules felt in its wall, an anastomosis was therefore made between the small intestine just above the ileo-cæcal valve and the transverse colon (Littlewood's bone-plates being used). The man did well at first but died about six weeks later with ulceration at the site of the obstruction. Fæces had passed into the short circuited portion of colon and had been prevented returning by the ileo-cæcal valve. The sketch shows the parts as seen *post-mortem*.

Dr. **Wood** read notes of a case of "Nephrectomy for Stone," in which owing to the slipping of the ligature on the pedicle there was great loss of blood; the patient becoming collapsed and pulseless. Two pints of saline solution were injected into the veins and oxygen gas inhalations commenced, the patient rallying immediately and making a good recovery.

◆

CATHOLIC UNIVERSITY MEDICAL SCHOOL MEDICAL AND SCIENTIFIC SOCIETY.

Meeting held Monday, February 26th.

Dr. **Birmingham** in the Chair.

Dr. H. **Byrne** showed a case of "Subpectoral Abscess."

Mr. **Forrest** showed a patient from whom a "Frontal angioma" was removed.

Dr. P. K. **Joyce** exhibited a dysenteric colon showing great thickening of the muscular wall and the usual rugous condition of the mucous membrane.

Dr. **McWeeney** gave a short account of the pathology and etiology of dysentery; great importance was attached to ulceration, which began in the sub-mucous tissue. The most recent researches had conclusively proved the cause of dysentery to be a small protozoon, about thirty times the size of a white corpuscle; this animalcule was invariably found both in the diseased intestine and in the hepatic abscesses which frequently accompany tropical dysentery; the pus from these abscesses invariably caused acute dysentery when injected into cats' intestine.

Dr. **O'Carrel** said he had seen a great many cases of dysentery during the epidemic, which occurred about six years ago in the Richmond Asylum; in one case the disease had been undoubtedly conveyed from one patient to another by an enema tube.

Mr. **M'Ardle** showed (1) frontal angioma showing cavernous tissue like the corpus cavernosum penis; (2) cancerous section showing the peculiar nodular brown outgrowths, which Mr. M'Ardle said he invariably found came away with the fæces in these cases, hæmorrhage was of rare occurrence; (3) an enormous renal tumour which had been successfully removed; a photograph was exhibited showing the various lines of incision adopted in nephrectomy. Mr. M'Ardle preferred that through the linea semilunaris.

Dr. **Smith** showed specimens of tubes and ovaries removed for dysmenorrhœa. The uterus had been twice curetted to no purpose; when the abdomen was opened, the uterus was found cancerous.

Mr. **M'Ardle** asked if the mucous membrane removed by the curette had been examined microscopically?

Dr. **Smith** replied that he considered no safe diagnosis could be made from an examination of the mucous membrane alone.

Mr. **O'Gorman** read a paper on "Effects Noted after Section of the Ulnar Nerve." S. K., suffered from neuroma of ring finger five years ago. The tumour was removed, but pain returned, and the ulnar nerve was resected. Trophic ulcers then formed on the forearm, which were cured by the electric battery. The little finger then became gangrenous and gave great pain, although its nerve supply had been apparently cut off. The finger was then necessarily amputated.

Mr. **Forrest** said he had seen a great many cases of neurectomy in St. Vincent's Hospital. He referred to the very rapid growth of nerves after section.

Mr. **M'Ardle** said he believed lesions of bone rarely followed destruction of their trophic nerves, but that irritation of the nerves by injections of ether, &c., might cause the destruction of osseous tissue. *The trophic ulcers were caused by a descending neuritis.*

Dr. **Shine** mentioned a case in which complete sensibility returned to a leg six weeks after resection of the great sciatic.

Dr. **Coffey** referred to the probability of ingrowth of nerves at the periphery.

Dr. **Mooney** read a paper on "Dislocation of the Lens."

Dr. **Birmingham** pointed out the great tendency of the lens to dislocate outwards owing to the resistance of the vitreous.

France.

[From our own Correspondent.

Paris, March 17th.

Notification and the Water Supply in Paris.

The Prefect of Police caused to be distributed last week to all the members of the medical profession in Paris the block books for the notification of contagious diseases, on the cover of which is printed the two principal articles of the recent law and the names of the maladies to be notified. The actual epidemic of typhoid fever in Paris will furnish frequent opportunities for the use of these books, but little good from the ordinance, the real cause of the malady being the drinking water, which is about as impure as it can well be—15,000 microbes to the cubic centimetre! The question has been brought before the Académie de Médecine by M. Bucquoy, who proposed that the public should be warned officially to drink no water that has not been boiled.

Biliary Fistula.

At the Académie de Médecine, M. Dujardin read a paper on the "Treatment of Biliary Fistula." He said that in a person suffering from icterus caused by retention, in whom all medical treatment had failed, it was necessary to operate. If the operation be successful and the patient cured, he will find himself in quite another position as regards nutrition. In the ordinary condition, although the choledochus canal opens into the intestine where microbes swarm, its contents do not, however, contain any bacteria; the same does not obtain when a biliary fistula exists by which the microbes can penetrate and infect the liver. Again, the fistula opens into the intestine at a certain distance from the pancreatic duct, and this fact brings about intestinal dyspepsia, which soon reaches the stomach, creating similar disorders. It is necessary consequently to administer such antiseptics as salol and enjoin the patient to become as much as possible a vegetarian.

◆

Germany.

[From our own Correspondent.]

Berlin, March 16th.

The Title of "Professor."

There are a large number of teachers at the University, and their ranks and titles vary considerably. The different grades are professors, professors extraordinary, honorary professors, privat docentiæ, and privat dozenten with the title of professor. The latter class comprise privat dozenten who have previously been professors at another university, and, therefore entitled to the title, although only privat dozenten here, or privat dozenten to whom the Cultus Minister has granted the predicate or title. A large number of privat dozenten of all faculties of the different universities have had this titular distinction conferred upon them the last few years. In order to distinguish this class from the gymnasial professors, the Cultus Minister has recently made known that privat dozenten or privat teachers who have received the title of professor shall be allowed to style themselves "university professor," whilst hitherto their official designation has been "privat dozent and könig professor." This innovation has been very pleasing to the privat dozenten of the Medical Faculty, on account of the useful effect it may have on their practice. The title of professor has also been granted to a number of medical men who have never been engaged in teaching. Thus, quite recently Dr. Johannis Israel, Directing Surgeon of the Jewish Hospital, was granted this titular distinction, although he has never had any teaching connection with the university. In the same way the Directing Surgeon of the Friedrichshain Hospital, Dr. Eugen Hahn, the Director of the Lazarus Hospital, Dr. Langenbuch, the Aural Surgeon-General, Dr. Trautmann, have in earlier times received the distinction, and in all cases this has been granted in recognition of their distinguished activity and their high professional standing.

At the meeting of the medical society of the 21st ult. Hr. A. Fraenkel gave an address on

Arterio-sclerosis after Syphilis.

He said the question of the origin of aneurisms, so far as syphilis was concerned, had been very variously answered. Walsh was of opinion that syphilis was the foundation of aneurism in 60 per cent. of the cases, other writers went further and put the percentage at 80. The speaker had carefully observed clinically nine cases of aneurism during the past four years, and had the opportunity of an examination post-mortem in every case. Five were women and thirteen men; four were over 60 years of age; ten were under 50, six below 40. The remark had been already made that in proportion to the ordinary arterio-sclerosis of old age aneurism was met with at a relatively early age principally from the middle of the twenties to the end of the forties. This circumstance made it possible that some special condition must be in action. Amongst the speaker's 19 cases syphilis was certainly present in 10, in six of the patients under 50, and four of those under 40. The proportion of syphilitic cases in his series was therefore about 50 per cent. As to the mode of origin of true aneurism different theories were propounded, especially two which had been called the mechanical theory and the inflammation theory. The mode of origin was of importance when we had to decide whether an anomaly of constitution was to come into consideration or not. Anatomically the mode of origin was very difficult to determine, as we could not determine whether the arterial changes were syphilitic or not. The preparation shown was of special interest, inasmuch it was not a true aneurism but an advanced and very extensive arterio-sclerosis in a comparatively young person, in whom undoubted anatomical changes of cardiac syphilis were present. A woman, æt. 37, was admitted under the speaker's care last year with symptoms of valvular insufficiency. The patient frequently complained of headache, pains, and attacks of faintness. She was discharged improved. The diagnosis was aortic valvular insufficiency, resulting from an antecedent reticular rheumatism. The husband of the patient was syphilitic. The patient had suffered from swellings of the head that had burst, and the cicatrices were still visible. At the commencement of the present year the patient returned with symptoms of cardiac trouble which differed from that present before in being characterised by violent attacks of angina pectoris. The patient did not come out of one of the attacks. The anterior and left coronary artery were quite permeable and unchanged, the right on the contrary was totally obliterated at its point of entrance into the aorta by an extensive arterio-sclerosis. That these changes were of a syphilitic nature was shown by the presence of a cardiac gumma, that had a length of 4½ ctm.

At the Dermatological Society, of the 13th ult., Hr. Mendel gave an address on

Syphilis Late in Life.

By syphilis late in life, he meant those diseases that had been acquired by men about 55, and women about 45. On the basis of 157 cases from private practice and from his Klinik, Sigmund considered syphilis late in life, both in regard to the number and character of the symptoms, and the liability to relapse to be comparatively mild. In opposition to this, Dulouy, basing his opinion on 131 observations, came to the result that late in life the disease was very obstinate, and very grave from affections of the abdominal viscera. Taylor was of the same opinion. Still more scanty are the literary data on diseases of the nervous system in syphilis of old age. The speaker added four cases.

The first case was a man, æt. 60, who, in 1885, had a neuro-chancre. Although steadily treated by mercury, he had cerebral symptoms culminating in unconsciousness. When this passed off, there was aphasia, hemianopsia, and right-sided paresis. There was certainly specific endarteritis of the artery of the Sylvian fissure, as the heart of the patient was perfectly sound, and no other signs of arterio-sclerosis could be found. Under the use of potassium iodide, the whole of the symptoms disappeared, and from that time, the patient had been perfectly well, although for caution's sake, he still took the iodide from time to time.

The second case was the wife of the first patient, and became infected in the fifty-third year. With the exception of ulcers in the fauces, no other sign of syphilis was present. There were painful swellings on the parietal bones of the skull, the pupils much contracted, reacting slowly to light, the lower extremities weakened. Potassium iodide. After three months' treatment, all the symptoms disappeared, headaches occasionally returned, but they always disappeared on giving the iodide.

The third case was that of a man, æt. 59, who had become infected four years previously. There were giddiness, facial paralysis, and left-sided hemianæsthesia. The affection was assumed to be arteritis of the left basilar artery. Under treatment, the giddiness disappeared, but the condition otherwise remained unchanged.

The fourth case was that of a man, æt. 55, who had an apoplectic attack. There were broad condylomata, a few weeks before he was said to have had an ulcer and a rash. There was some probability that there was a connection between the syphilis and the cerebral hæmorrhage. He thought it desirable that all cases should be collected.

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, March 16th.

Eighth International Congress of Hygiene and Demography.

The preliminary arrangements for the Eighth International Congress of Hygiene and Demography, to be held at Budapest from the 1st to the 9th of September this year, are already far advanced. The programme of its scientific part was very favourably received abroad, and many communications of approval have been sent to the General Secretary. The interest which foreign countries take in this Congress is best shown by the great number (440) of eminent scientists who have already promised papers for the various Sections. The number of the Sections has been increased by one, this being the twentieth, under the title "General Samaritan Affairs." This Section will treat and finally decide all the important questions falling within its sphere. The interest of the Congress will be enhanced by the circumstance that the medical officers of the German railways and the cremation societies will hold their meetings at Budapest in connection with this Congress. The Congress will be opened by His Imperial and Royal Highness Archduke Charles Louis. The introductory meeting will take place in the building and garden of the National Museum, the classic ground of our metropolis. The Corporation of the metropolis will arrange a splendid *soirée* at the halls of their redoute for the reception of the Congress. The 6th of September is reserved for minor excursions, such as the inspection of public institutes and edifices, a trip to Balatonfüred, Siofok, and by invitation of Count Nicolas Esterhazy to Totis, also excursions to the Szechenyiberg, the Island of St. Margherite, &c. The arrangements for the excursions to be made after the closing of the Congress have been enlarged, so that besides a voyage to Constantinople and Belgrade, excursions to Tatrafüred, Agram-Fiume, and to Bosnia and the Herzegovina have been added to the programme.

Tabes Spinalis.

Prof. Obersteine read a long paper at the last meeting of the Gesellschaft on the Pathology of Tabes of the Spinal Cord. He said that the greatest number of authors in nerve diseases placed the origin of the morbid changes in the posterior roots of the column, but he was still of opinion that this theory of tabes was not sufficiently explained. He maintained that the primary changes were not in the nerve fibres nor in the dark centres of the ganglia. He had worked out many of these cases with Dr. Redlich with a strong desire to locate the primary morbid change. In all his sections which were certainly affected in the posterior roots, but in such a way that compression or strangulation was apparently the first cause. He concluded that a form of meningitis originally existed which slowly invaded the roots by the thickening of the pia mater and finally strangulating the posterior roots. He considered this opinion borne out by the atheromatous condition of the vessels; also by the fact that there existed some relationship between tabes and syphilis which produced an atheromatous condition of the vessels. The lancinating or cutting pains pointed to pressure on the sensory nerves. The therapeutic results obtained by antisyphilitic treatment in tabetic patients, particularly when the pia mater was not too far implicated, pointed to the support of his theory in the favourable results obtained. He was confident that the changes commenced in the covering of the cord and slowly advanced, implicating the fibrous tissue. If we accepted a toxic production the hypothesis could be easily borne out to ocular demonstration with this as the starting point.

Spinal Abscesses.

Schlesinger also read a paper on the sparsity of abscesses of the spinal cord. He said that cerebral abscesses were often met with, but that spinal abscesses were of great rarity, only seven recorded cases appearing in literature, four of whom were idiopathic, and three traumatic. The first of these was recognised in life by Nothnagel, who in *vivo* diagnosed it as bronchiectasis. It was the case of a man, æt. 31, who was sent from Prof. Lang's wards after suffering from cystitis and urethritis, after which a prostate abscess formed and was incised. Fourteen days later a pain suddenly commenced in the neck, the spine becoming stiff and thickened till death, which was preceded by paralysis of the extremities. The post-mortem revealed purulent meningitis spinalis with pus in the spinal cord which extended along the greater part of its length. The abscess confined itself mostly to the region of the posterior horns, along which myelitis could be traced. The case is worthy of remark on account of the propagation of pus from the meningeal affection extending into the spinal cord as well as from an etiological point of view. It is urgently held by some that after gonorrhœa a gonorrhœa myelitis must of necessity arise, which is a dangerous axiom to accept from our present knowledge of histological facts. In this case the gonococci could not be found, although diligently searched for in the spinal colum or meningeal exudations. Staphylococci, however, were in abundance, and it is not improbable that these may have been of a gonorrhœal origin and produced the evident metastasis.

Sternberg demonstrated a preparation with diffuse purulent meningitis implicating the spinal column. The specimen was taken from a man, æt. 28. It clearly showed the invasion of the septa with thick round cell infiltration appearing as wedges in the lateral columns; the axis cylinders were swollen and the roots of the nerve exhibited diffuse nephritis. In every case of meningitis there is a deposit leading on to myelitic disease, but rarely forming abscesses. Dr. Nobel said that no gonococci could be found in this case.

The Operating Theatres.

ST. MARY'S HOSPITAL.

Removal of Penis, Scrotum, and Testes for Epithelioma.—Mr. Ernest Lane operated on a man, æt. 51, the subject of an epithelioma which had been steadily increasing for a year previous to admission to St. Mary's. The penis was represented by a cauliflower-like excrescence bleeding freely and discharging offensively; the skin of the scrotum was hard and infiltrated with growth, and the inguinal glands on both sides enlarged and cancerous. The growth was removed by lateral incisions in the femoro-scrotal folds meeting posteriorly in the middle line of the perinæum and united superiorly by a horizontal cut above the symphysis pubis. The spermatic cords were isolated, secured with a double ligature, and divided at the external abdominal rings. The crura of the penis were detached from the pubes, the corpus spongiosum was dissected out, and the whole penis and scrotum with its contents removed. The urethra was then attached to the integument of the perinæum and the edges of the skin approximated as far as possible. The glands were next cleared out of both groins and an infiltrated cord extending along the suspensory ligament of the penis towards the umbilicus was dissected out. Mr. Lane remarked that in severe cases of epithelioma of the penis requiring removal of the whole organ a simultaneous removal of the testes and scrotum was also advisable; in his opinion, if the testes were left after removal of the penis the growth might return in them, and further, the physiological activity of these glands might be a source of considerable annoyance and discomfort to the patient. Removal of the testes, he said, did not seem to be attended by any additional shock. To render the operation complete, it was, he thought necessary to extirpate the inguinal glands on both sides, and also in the present case to carry the dissection up towards the umbilicus so as to remove an epitheliomatous infiltration of the suspensory ligament of the penis.

ST. THOMAS'S HOSPITAL.

Varicocele.—Before the operation was performed by Mr. Anderson, it was found impracticable to administer an anæsthetic owing to the violent struggles of the patient, (a youth, æt. 19), prior to the setting in of complete unconsciousness. The young man then consented to submit to the operation without an anæsthetic. The operation was done by a modification of the subcutaneous plan. The vas having been isolated and displaced backwards, while the varicose veins were held by an assistant, a fine tenotomy knife was passed through the scrotum between the veins and the vas, and over this was passed a straight needle bearing a strand of silk; a second puncture was made in the same manner an inch higher. The veins were now allowed to fall back, carrying with them the silk ligature, and the needle was passed back again through the same incision in front of the veins between these and the scrotal integument. The veins now included in the loop were ligatured and the thread cut off close to the knot, the ligature remaining completely buried. The second puncture was treated in a similar manner. Thus a segment of the veins was isolated between the two ligatures. It may be noted that the lower ligature was knotted first in order that the blood might be emptied as far as possible from the included portion of the veins. The patient showed no sign of suffering during the operation, and said that the pain during the passage of the knife and the tightening of the ligatures was very trifling. The wound was dusted with boracic powder and dressed antiseptically; the whole operation only occupied three or four minutes. Mr. Anderson remarked that he had abandoned the open operation during the last eighteen months in favour of the present procedure, the advantages of which appeared to be its brief duration and the invariable absence of septic combinations. The patient may be discharged with safety at the end of ten days, and perhaps earlier. The results in a considerable number of operations have, he said, been perfect. There is very little local swelling or tenderness, and in the cases that could be followed the cure has been permanent. It is no small advantage, he thought, that the operation can be performed, as proved by the present and by a previous case, without the aid of an anæsthetic and without seriously trying the powers of endurance of the patient. The ligature of the veins in two places appears to render relapse almost impossible.

Exploration of Kidney and Ureter.—The same surgeon operated on a patient who had been the subject of a nephrotomy a month before. The man, æt. about 35, had been suffering from symptoms pointing to renal calculus on the right side for a twelvemonth. The kidney was cut down upon, and on incision the cavity was found to be enormously distended with mingled pus and urine. A careful examination was made for a calculus, but none was found, and a drainage tube having been introduced, the wound was closed around it. The patient recovered from the effects of the operation, but the symptoms remained unrelieved, the man still suffering great pain along the course of the ureter. The present operation was undertaken for the purpose of ascertaining whether a stone was arrested in a part of the tube. A longitudinal incision of about 4 inches in length having its centre opposite the umbilicus was made through the right rectus about an inch from the median line; the hand was then introduced and a careful exploration made along the whole tract of the ureter; the tube could be felt thickened, and somewhat sinuous in its course from the kidney to the bladder, but no stone could be detected. The lower end of the kidney was harder than normal, but the resistance did not suggest the presence of a calculus, and as the patient was in a feeble condition the wound was closed by a deep continuous peritoneal suture of catgut and a row of wire stitches passing through the rectus and integument. Mr. Anderson remarked that the failure of the present operation to lead to the detection of a stone of course did not conclusively prove that a calculus did not exist; it, however, rendered most probable that the symptoms were attributable to another cause, and this, from the condition of the kidney at the time of the first operation and from the feeble condition of the patient's health, is, he thought, most likely to prove a tubercular affection involving both organs.

WEDNESDAY, MARCH 21, 1894.

SCHOOL OPHTHALMIA.

In a former article we discussed Mr. Hutchinson's views bearing on the alleged increasing spread in our large public schools of a form of ophthalmia which, if neglected, may terminate in typical granular lids. Mr. Hutchinson, in fact, asserted with uncompromising emphasis that the eye troubles which have for years caused so much suffering and permanent deformity among the waif population of our workhouse schools are now gaining a foothold among the children of the well-to-do who are aggregated in the large public schools. It cannot be denied that for some months past a feeling of uneasiness has pervaded the public mind in respect of the indisputable prevalence of ophthalmia in some form or another among schoolboys, and this feeling has had for effect to add greatly to the anxiety of those who are responsible for the management of the schools and to the responsibility of the medical men to whom is entrusted the duty of looking after the sanitation of such schools. Mr. Hutchinson stated his views with great precision, and his opinion is undoubtedly entitled to very great weight. Nevertheless, it must be admitted that during the two evenings' discussion at the Ophthalmological Society he received very little support from the specialists who joined in the fray. The first thing that will strike the impartial reader of the reports is that even among specialists the greatest confusion obtains as to the identity of the various forms of ophthalmia. According to some the form of ophthalmia which leads up to granular lids—the form which from old associations is commonly known as workhouse ophthalmia—is attributable to a special microbe, derived according to German pathologists more or less indirectly from the genitals. According to this school, granular lids can result from this form of ophthalmia and from no other, in fact, it is workhouse ophthalmia *ab initio*. Others, and among them Mr. Hutchinson, hold that the ophthalmia which is just now so prevalent can and does give rise to granular lids, though in its earlier stages it may not be easy to distinguish from simple or muco-purulent ophthalmia. It was suggested as a means of reconciling the conflict of experience and opinion that granular lids may result from an intercurrent attack of ordinary ophthalmia in children who exhibit the tendency to adenoid overgrowth which is so commonly met with in the denizens of towns, and finds expression elsewhere in the so-called granular pharyngitis, &c. Mr. Hutchinson insists upon the necessity of educating the profession generally to recognise the gravity of the affection in view of its possible consequences; but seeing that specialists are hopelessly divided, not only on the pathology of the affection, but on the practical question whether this or that child is or is not the victim of granular lids, the chance of the general practitioner attaining a superior degree of diagnostic acumen must be remote indeed. There was, however, at least one point upon which the ophthalmologists, in solemn conclave assembled, were agreed, viz., that these cases ought always to be treated by specialists; but until they themselves are agreed in their diagnosis their *dicta* will fail to command the respect to which they would, under other circumstances, be entitled. That some of the lads at our public schools should contract workhouse ophthalmia is, after all, not altogether a matter for extreme surprise if certain insinuations are to be accorded credence. We know that, whatever its pathology may be, workhouse ophthalmia is a malady which flourishes under certain well-defined conditions, viz., defective diet and imperfect sanitation. There is reason to believe that the sanitary conditions under which the children of the rich are sometimes called upon to live at these expensive schools do not materially differ from those which obtain in parochial schools. This points to the necessity for some systematic inspection, either by the Government or by the local authority, and this is a point which is now likely to receive immediate attention. Taking a broad view of the situation, it would seem that, though imperfect sanitation is not directly responsible for the affection, which is transmitted principally, if not exclusively, by contagion from person to person, it does, by predisposing the inmates to adenoid overgrowth and generally impairing the standard of vitality, pave the way to contagion. While, therefore, strict isolation and appropriate local treatment, preferably of a mild description, are urgently called for in presence of an outbreak, the epidemic tendency of the affection can only be effectually guarded against by greater attention to the elementary laws of health, which are the same for the rich as for the poor.

◆

DUST DISEASE IN THE POTTERIES.

During the course of last week a deputation of manufacturers of china and earthenware waited formally on Mr. Asquith. Their complaint, in effect, was that the new rules were so stringent as to threaten their future commercial prosperity. In the interests of workers in dangerous trades generally we are glad to state that they derived little or no encouragement from their official interview. In firm but courteous language Mr. Asquith furnished the key to the Government position, although he afforded no hope of any changes in the direction desired by the deputies. He pointed out that the special rules to be applied to the pottery industry had been recommended only after the fullest inquiry into the conditions of the trade by the Departmental Commissioners; in other words, that the suggested changes had been advanced in the light of full knowledge and deliberation, and were presumably founded on a basis of justice and expediency. Indeed, the proposed regulations have been already adopted, in whole or in part, by a few humane masters. But it is to be feared that humanity of this sort is only too likely to involve disinterested employers in loss, for in these days of keen business competition the cost of production is cut down as nearly as may be to vanishing point. Hence, the manufacturer who deals justly with his workmen is likely to be at a disadvantage in his competition with the manufacturers who exact their capitalist advantage to the uttermost farthing. Moreover, it is clear that reform in the pottery trade cannot be delayed because there are a few righteous men amongst many offenders. Of late years the principle which has been adopted, not only by political economists and trades unionists, but also by our representative legislators, is that workmen must be protected by absolute prohibitory and penal legislation. History has shown over and over again that where the master's pocket is concerned permissive legislation is worse than useless. Acting upon these convictions, the Commons have insisted on the exclusion of the voluntary contracting-out clauses inserted by the Lords in the amended Factory Acts Bill. Returning to the pottery trade, it will be instructive to inquire a little into the facts. First of all we find ourselves confronted by an excessively high death-rate. If we turn to Dr. Ogle's tables showing the comparative mortality of males, 25 to 65 years of age, in certain dust-producing occupations, from phthisis and diseases of the respiratory organs, we find that the average for England and Wales is 402 per 10,000. The lowest place on this list is occupied by the coal miners, who stand at 328 per 10,000, a figure actually less than that of the general average. Passing over a number of other occupations of a similar class, such as bakers, wool manufacturers, and quarrymen, we will confine our attention to the three deadly ones which come last on the table, namely, file makers, earthenware manufacturers, and Cornish miners. All three are exposed to the common condition of a close atmosphere which is laden with a dust that acts not only as a mechanical irritant, but also as a poison. Curiously enough, this poisonous metal, lead, is the same in all three cases. The file cutters strike their files on a lead cushion, the potters use a lead glaze, and the Cornish miners work in the ore. The earthenware manufacturers suffer enormously from bronchitis and emphysema, and also from "potters'" asthma and phthisis. They do not suffer relatively so much from phthisis as the file cutters or the Cornish miners. Thus, the file makers showed 433 deaths from phthisis, and 350 from other diseases of the respiratory organs, out of a total of 783 per 10,000. The potters, out of a total of 1,118, suffered in the proportion of 473 phthisis and 645 other respiratory diseases. Their record, however, is beaten by the Cornish miners, in whom the figures are respectively 690 and 458 out of a total of 1,148. There can be no doubt that this death-roll includes a large margin of preventible disease. It is probable that even if placed under the most stringent regulations these trades would always remain unhealthy, but that is no argument against enforcing such regulations. We trust that the Government will assume a firm and decisive attitude with regard to the Commissioners' report on the dangerous trades. The principle of guarding the workman against avoidable risks is not only humane, but it is also directly conservative of the sum total of national wealth. That is to say, the ordinary taxpayer has to support the human wreckage from these disastrous trades in infirmaries, asylums, prisons, and other refuges for the workman who has become crippled in producing wealth for the capitalist. The not altogether unreasonable contention has been advanced in some quarters that the manufacturer who reaps the profit of a dangerous trade should support his disabled workmen. Individually, these capitalists are no doubt humane and kindly men; it is only when they get together that they become callous and calculating. Anyway, their withers have been evidently wrung by the recommendations of the Departmental Commissioners, and we are glad to see that the Home Secretary has shown no sign either of compromise or of delay in bringing about this much-needed domestic reform.

◆

THE OPIUM COMMISSION.

We learn by the last mail that the Opium Commission sat daily, in spite of a rising temperature (the thermometer standing at 88° Fahr. in the shade), and that a large number of members of the profession had been under examination. The consensus of opinion expressed by both European and native practitioners, especially those with the largest and most varied experience, was to the effect that the use of opium was on the whole far more beneficial than harmful to the native population of India. Certainly the habitual use of the drug does not lead to the serious consequences which follow the use of alcohol, or beer, and Dr. Blaney, with experience as Coroner for twenty-one years in Bombay, said, "No case of an opium-eater dying in the streets had come under his notice." Opium, when taken in small quantities as it is by natives, is neither morally nor physically injurious. With the greater number of persons its effect is to render the mind more active and the imagination more vivid. In moderate doses it is known to act as a tonic and stimulant, the individual as a rule having no tendency whatever to the commission of any crime or act of immorality. He is most certainly able to follow his daily avocation and to undergo a greater amount of physical and mental strain than non-consumers or those who resort to the use of alcohol. In larger doses, however, it impairs appetite, and acts as a check on the secretions generally. The opinion appears to be universally held among the profession in India that the use of opium by the people of India cannot be strictly prohibited without producing disastrous effects upon the country at large. Moreover, if the use of opium were suppressed or in any way greatly interfered with, some other form of nervine stimulant, most probably alcohol, would in a very short time replace it, and thereby the evil would be greatly aggravated, since alcohol would certainly induce degenerative changes in the tissues of the body and offspring, and sow the seeds of moral degeneracy, the habitual use of alcohol being always associated with crime and immorality among all classes. It is a fact that 90 per cent. of prostitutes and their paramours are spirit-drinkers, while scarcely 10 per cent. of them resort to opium; so that it may be inferred that the general use of alcohol would on the whole be attended with far graver consequences among the people of India, the lower classes in particular, on account of a prevailing higher temperature, and other climatic variations, than those of England and other European countries. From another point of view, a political one, it is the firm conviction of those who have spent the best part of their lives, extending over a period of twenty, thirty, or more years, that any attempt to impose prohibition in the native states of India would be certain to invite general discontent, hatred, and disloyalty throughout India, which it is confidently believed would culminate in a rising of the natives, compared with which the Mutiny of 1857 would be as child's play. By the latest accounts received we find the Commission engaged in taking evidence on the financial difficulty, no slight one, that must ensue should the withdrawal of the existing tax on opium be insisted on. With this the labours of the Commission will practically terminate, but the consideration of the Report will yet take time before it can be presented to Parliament. So far as those who are in a position to see the consequences that would follow prohibition, there is positively nothing to be gained in return for the loss of prestige and hatred incurred, beyond the knowledge that a society of well-meaning but meddlesome and ignorant people had done their best to destroy our rule in India.

◆

Notes on Current Topics.

Dental Hospitals.

It is unfortunately the fate of Dental Hospitals that they do not directly appeal to the sentiment of the benevolent public as do the general hospitals. No operations involving the loss of life or limb take place within their walls, and everything associated with dentistry is, by comparison with surgery, looked upon as trivial. The public do not take the broader view that the after health is so much dependent on the teeth that those who cannot afford to go to a dental surgeon must go to a dental hospital or suffer untold miseries; nor do they take into consideration the fact that dental hospitals are the nurseries of future practitioners without which those who are possessed of means would be unable to command the same skilful treatment of their so-called "trivial" complaints: and so the chairman of the Dental Hospital of London had to confess at the annual meeting on Thursday last that out of £40,000 required for the new building, £9,700 only had been promised, and the whole of this except £2,000 by the dental profession. This is not as it should be: the institution is much sought by the poor; it is well managed, and students are excellently taught, and we sincerely hope the public will more fully recognise its claims. We might venture to suggest that £40,000 seems a large sum to ask, and that instead of a new building, the committee might extend in the rear of their present premises and gain all the additional space required at less than half the sum asked.

Poisonous Meat.

However far Great Britain may be in advance of Continental countries as regards sanitary matters generally, it is probable that she lags far behind them in the particular of the supervision of meat. In some of the German towns, at any rate, it is made a condition of the public health professorships that the holders do so many hours' practical work daily in the *abattoirs* That there is a field for a similar highly-skilled control over our own meat supplies is proved up to the hilt by the cases that crop up from time to time in the police courts. Only last week a dealer was summoned before the Guildhall Court for sending the carcases of three diseased pigs to the Central London Meat Market. It was sworn in Court that the carcases were not half the weight they should have been, that the animals had been diseased, and that the results to persons eating such meat might be disastrous. The Medical Officer of Health for the City stated it was one of the worst cases he had ever seen. On the strength of this and other evidence the Alderman said he had no hesitation in saying that the defendant stood in the light of a man who had sold poison. He had deliberately sent bad meat to the market. We are glad to say that the defendant was sentenced to two months' imprisonment.

A Novel Suggestion.

A CURIOUSLY novel suggestion has just been made by a correspondent to an American contemporary. It is to the effect that a large building should be erected in New York for the sole purpose of providing consulting rooms for "physicians." [We never seem to hear of "surgeons" in America.] The idea appears to be to have a very extensive general waiting room, and several floors of rooms, the rooms being used by "physicians" for seeing their patients in. Incidentally it is mentioned that the owner would have to adopt some rules for preventing undesirable tenants from becoming attached to the establishment. Certainly this proviso would be most essential under the circumstances; but it is difficult to see how the scheme could be worked harmoniously, even with the desirable tenants who patronised it. The risks, we should imagine, of the gravitation of patients in the wrong direction would be immense, and the small talk in the general waiting room might be well calculated to result in enabling some of the doctors to pay their rents with ease, and in causing a difficulty in this respect to others which might be serious.

Insanitary Dwellings.

THERE can be little doubt that the lack of a sufficient number of sanitary inspectors places very great obstacles in the path of public health progress. Without a strong administrative staff no scheme of legislation, however well considered and far-reaching, can be of any real efficiency. To take an instance, the Factory and Workshops Act, which is fairly comprehensive, is openly and constantly defied by the smaller tradesmen and manufacturers. Indeed, nothing but a house-to-house visitation could ensure the carrying out of that useful measure. A similar observation applies to many other of our more domestic laws, and perhaps most of all to insanitary house property. The British public has grown accustomed to "shocking stories" and "horrible revelations" dealing with the slums and rookeries. A tale of the kind was told at an inquest held last week in the East End of London. The coroner's officer declared the house to be unfit for human habitation. His testimony was borne out by the Parish Medical Officer, who emphatically said he should not like his dog to live in the room. When he reached the house it was daylight, but he had to borrow a light to see where the patient was lying. The staircase leading to the room was positively dangerous to walk on, and in going up he had to use his hands as well as his feet. Other witnesses concurred as to the filthy and dilapidated state of the premises. And this is in the richest city in the world! Sanitary matters in the East End of London are notoriously bad, and its staffs of inspectors miserably and totally inadequate to the work they are supposed to undertake.

The Organ of Corti.

THE organ of Corti has for long had the reputation of being one of the most beautiful examples of animal creation. It formed the subject of Dr. McKendrick's lecture at the Royal Institution recently, and he had much that was interesting to say about it. He agrees with Helmholtz's theory respecting its mechanism, which presupposes the existence in Corti's organ of many vibrators tuned to all the tones the human ear is capable of hearing, and passing through a range of eleven octaves. Moreover, he showed that the basilar membrane on which Corti's organ rests contains at least 24,000 delicate fibres running parallel side by side, and he added that the fibres of the cochlear division of the auditory nerve have been found to number no less than 18,000! The lecturer further pointed out that the ear feels the touches of different kinds of sound waves, while it analyses them into their constituents, and he concluded by saying that this harp, not of a thousand, but of ten thousand strings, must always excite our wonder and admiration.

Christ's Hospital in 1877.

IN view of recent revelations as to the sanitary arrangements in Christ's Hospital, it is of interest to learn what was the state of affairs seventeen years ago. From a report issued in that year we learn that extensive alterations had been made in the system of drainage, in consequence of four cases of typhoid which had lately occurred among the scholars. It is stated that all drain-pipes were carefully and effectually ventilated, and all waste-water carried off by a system separate from the soil-pipes. The writer of the report was apparently satisfied with the state of the drains in 1877, a fact which is in startling contrast from the recent wholesale condemnation the the same drains have received in 1894. The explanation is probably to be found in the higher sanitary standard of the last decade of the century. After all, judging from the rate of recent advances, a period of seventeen years is ample for an extended crusade by the army of preventive medicine.

American Quack Cures for Inebriety.

FURTHER particulars have oozed out about the cases of drunkenness treated in Dundee, several people having written to say that to their certain knowledge in many instances the "cures" had only been very temporary. One of the Edinburgh lay papers has taken up the subject with commendable zeal, and has collected a number of facts intended to show the public what utter frauds these American systems are. Tyson's cure seems to be run by a company, Messrs. L. B. Tyson and Co., Limited, of which a Mr. George T. Stephens is an assistant secretary and agent in this country. The latter gentleman is connected with B. W. Hair and Co., chemists, High Holborn, London, whose names will be remembered in connection with a recent prosecution, and who in the present instance, after the first article appeared in the Edinburgh paper, wrote an extraordinary reply to it, in which he tried to explain away the fact that Tyson's agent in Australia was fined under the Colonial Poisons Act for selling without a licence a poisonous drug. As we have stated before, a committee of rabid teetotallers in Edinburgh has been gathered together to boom the great discovery in that city: they are to commence work, we believe, this week if enough sufficiently debased drunkards can be obtained to make it worth while. Some curious details, also, have been published lately about a "Glasgow Metabolic Institute," run by an A. J. Currie, M.D., Cinn., O., in conjunction with a Dr. A. Nairne, who is entered in the Medical Directory as L.R.C.P. Edin. 1874, and then in brackets "Currie and Nairne." Dr., Nairne is further stated to have been one of Currie's cures, and his position in connection with an unregistered practitioner is at present, we believe, under the consideration of the Royal College of Physicians. Several cases reported at the time with a flourish of trumpets as having been cured at this Metabolic Institute lapsed in a few days, as we only could expect. It is not known by which method "Dr." Currie treats his patients—some say that it is Tyson's, others Keeley's. The doctor himself does not seem to mind which it is called by, and we do not suppose it really matters. Keeley's people in London have, however, written to say that it is a fraud to say that the metabolic cure is the same as theirs, but that they intend shortly to allow the Glasgow people the opportunity of the only true and genuine cure.

The Vivisection Controversy Revived.

The cause of the experimental physiologists—known to fanatics as "Vivisectors"—has always had an able champion in Mr. Victor Horsley, and in an interview which a representative of an evening London journal had with him the other day, the case for "Vivisection" was once again distinctly stated. Probably it is not generally known that Galen played a prominent part in advancing our knowledge by experimental physiology. From Aristotle downwards it was believed that the function of the brain was to cool the passions of the heart, because when a brain was dissected it was found to be cold. Galen showed by the simple plan of feeling the living, and not the dead brain, that it was as warm as the rest of the body. That upset the elaborate theories of the ancient anatomists. By dividing the spinal cord Galen next discovered that the brain was the source of intellectual energy, and developed the impulses which descended to the spinal cord to reach the muscles. Galen also made valuable discoveries as to the structure of the cord itself. There is a famous story which tells how Galen alone of all the doctors in Rome, by his experimental knowledge, was able to cure a sophist of disease of the spinal cord, which he recognised to be at fault, though the symptoms were referred to the hand. Lastly, Galen also found out that the nerves were motor and sensory, and were the means of conduction of impulses from the brain to the muscles, and from the skin to the brain—and all this took place as long ago as 140–190 A.D., when penalties were likely to fall upon people who found out too much!

The Dublin Students.

We understand that the memorial of the students of the College of Surgeons' School, referred to in our last issue, was considered by the College Council on last Thursday, and as it was temperate and reasonable, was received by the Council in a conciliatory spirit. The matter was referred to the School Committee of the College, and the Students' Committee was requested to nominate three delegates to confer with the College Committee. Meanwhile the organisation of the Students' Association has made progress, representatives having been appointed from the School of the Catholic University to co-operate in the movement. The Royal College of Science, which is the teaching centre in Dublin of the Science and Art Department, is also the *locus* of a very serious students' *émeute*. One of the professors has given much dissatisfaction to the class in the performance of his duties, and the result was the presentation by them to the Council of the College of a round robin in which grave charges were made. The Council appear to have shelved the memorial, and the anger of the students thereat took the form of remarks of a very emphatic sort made within the College and in the presence of students and teachers. The Council, on this being reported, suspended the student who made the remarks, and fined him £10. The adjustment of the matter now rests with the Science and Art Department.

Illegal Operations.

The attention of the public has lately been drawn in a pointed manner to the frequency of the offence of criminal abortion. Several cases of a tragic nature have occurred in the metropolis, and others are reported with monotonous regularity from other parts of the country. Last week a Huddersfield offender was convicted of murdering a woman on whom she performed an illegal operation. Mr. Justice Collins sentenced the prisoner to ten years' penal servitude, a term of imprisonment which does not err on the side of severity, in fact, it is not altogether easy to understand why in this case the jury made a recommendation to mercy. The prisoner had committed a felonious act, which resulted in death, for which by English law she became responsible. The fact that the deceased was a consenting party is not material to the issue, for in all such cases the operation must necessarily be performed with consent. It is to be hoped that the justice meted out to this class of offenders will not err on the side of clemency.

A Sensible Order.

In the House of Commons last week, on a vote for Public Education in England and Wales, the Education Department was taken severely to task by an honourable member for insisting upon certain alterations—described as "fads"—being carried out in voluntary schools. On the question being asked by the Vice-President what these "fads" were, the reply was that one of them consisted in the Department requiring pegs to be placed in the lobby of a school for the children's hats and cloaks. "That is a fad, is it?" was the contemptuous rejoinder of the Vice-President. Subsequently the latter explained that "nothing was more unsatisfactory and more likely to lead to infection than to have the clothes of the children thrown together on a rainy day." We quite agree; the order for the pegs to be placed was both sensible and necessary. Apart altogether from the chances of infection, nothing could be more opposed to the principles of hygiene than to allow the damp overcloaks of children to lie for hours upon a table seething in their moisture until they were again required.

The New Order of Midwifery Practitioners.

DR. ROBERT RENTOUL gained a great victory at the recent meeting of the Lancashire and Cheshire Branch of the British Medical Association against the promoters of the "Midwives' Registration Association." The meeting was a special one, called for the express purpose of considering certain resolutions brought forward by Dr. Rentoul condemning the policy of those who are advocating the registration of midwives. No less than one hundred members of the branch attended in response to the summons. The opposition was represented by a certain number which was just large enough to add zest to the proceedings. After the resolutions had been duly proposed, seconded, and well supported, a long list of amendments was brought forward by the opposition. But the result of the voting revealed a melancholy state of affairs so far as the amendments were concerned. Only 12 could be found to vote in favour of them, and they were consequently rejected by 58 against. The original resolutions, therefore, on subsequently being put to the vote, were carried with only 12 dissentients. The result of this special meeting clearly shows that the members of his branch are quite prepared to follow Dr. Rentoul's lead in the organisation of the opposition against the proposed new order of midwifery practitioners. A victory such as this should be made the most of; it will encourage other medical societies to follow suit with the view of bringing under the notice of the Legislature the active feeling which still prevails throughout the profession against any registration of midwives. Parliament will be very loath to act, as previous experience in the same matter has shown, in accordance with the wishes of the promotors of the scheme when evidence is forthcoming of the widespread opposition of the profession.

Amendment of Notification Law.

DR. CAMERON, of Leeds, writes with reference to the complaint of Dr. Leslie Phillips, published in our issue last week, that the difficulties of administering the Notification law may be avoided by "give and take" between the notifying practitioner and the Medical Officer of Health. Quite true. If we lived in Utopia every patient would be delighted that the doctor should notify—every practitioner would be charmed to do so, and every medical officer of health would be proud and happy to advise his Authority to pay out fees without stint, because every notification would be genuine. In fact, if our lot were cast in Utopia, these matters would not concern us, because in a year or two there would be no infective disease to notify. But, unfortunately, we reside in a commonplace mundane sphere in which every man, woman, and child, without any exception, is influenced by personal interest. The patient will not be notified if he can help it; the practitioner will not notify him if it is to his interest to do the other thing; and the medical officer of health does not like either to allow infection to remain undetected or to ask his sanitary authority to pay for notification of cases which are not infective. What we say is that a law which totally ignores these influences and requires the whole world to do what it does not want to do, and provides no method for detecting or punishing evasion, is simply impracticable. It could not work, it never did work, and it never can work, and our advice has always been, break it up and make a new law.

The Chelsea Hospital for Women.

WHATEVER the nature of the public inquiry may be with respect to the allegations against the Chelsea Hospital for Women, we quite agree with certain members of the staff that the mortality records of the operations should not have been compiled from simply one year's statistics. Undoubtedly, in order to arrive at a more accurate estimate in the matter, the ratio of deaths in the operation cases should have been taken for the past five years at least. The injustice of taking only one year's statistics is obvious; an operator, for example, might have had a successful run of cases of, say, ovariotomy till last year; then he might have lost two or three, thus making his record appear very unfavourable. And the reverse would hold good. With reference to the report of the medical staff of which mention was made in our issue last week, a correspondent has drawn our attention to an entry respecting the death of one of Dr. Leith Napier's cases. We here quote the passage *verbatim.* "Abdominal section, emptying broad ligament cyst; death on the fifth day from septicæmia; operation to save life, but thwarted by sepsis!" "*Thwarted by sepsis*" appears to be quite a novel way of explaining a fatal result after an abdominal section. Whoever is responsible for the introduction of this new phrase should take credit to himself for suggesting a way out of a difficulty which few could have conceived.

Trained Nurses for Villages.

NOW that nursing has become so popular an occupation amongst women, the danger of overcrowding becomes more and more apparent. The supply of highly-trained nurses turned out yearly from our hospitals must in the aggregate amount to a very large number indeed. Many of them find lucrative employment among the wealthier classes of the community, while others devote themselves more especially to the service of the poor. Among the latter, too much praise cannot be bestowed on the district nurses, who do a large amount of valuable and self-sacrificing work in our alleys and by-ways. It has lately been proposed to provide a service of nurses in the County of Derbyshire. The Bishop of Southwell lately addressed a meeting on the subject, and in the course of his remarks said that they wanted trained nurses who would be always in reach in the neighbouring districts, ready for the manifold minor illnesses of a non-infectious character, for the accidents, bruises, and sores which were so constantly happening, and especially, he might say, for the arrival of babies in both village and urban districts. Not only should they be ready to discharge these duties effectually, but in cases where families were disabled by the temporary suspension from duty of the house-mother, they should be ready to take her place and keep the house in order, and look after the children. The list of duties thus detailed by his lordship is sufficiently comprehensive. Can anyone familiar with district nursing in the country, where long distances have to be covered in all weathers, and often over bad roads, imagine the nurse attending confinements? Besides, the medical men of the district would have something to say on the subject of subsidised competition of that sort. Under proper conditions, a district nursing scheme would be certain of a hearty welcome among local practitioners.

A Proposed Society of the Royal College of Surgeons of England.

A curious topic of inquiry during the past few days has been the statement contained in a circular letter addressed to all the Fellows of the Royal College of Surgeons, England, intimating that a movement was on foot to form a "Society of the Royal College of Surgeons, England." Numerous communications have been addressed to the Honorary Secretary of the Association of Fellows, seeking information in respect to what this announcement means. But we are informed that this circular carries with it its own explanation, namely, that, covertly, the object of this proposed society is to endeavour to throw discredit upon the Association of Fellows, to counteract its influence, and to form a combination of Fellows by which certain of those attached to London schools who have hitherto failed to be successful in gaining seats on the Council will be enabled to attain their desired ambition. An important meeting of the Committee of the Association of Fellows will be held to-day (Wednesday) at 18 Great Cumberland Place, Hyde Park, W., at 5.30 p.m., when the matter will come forward for discussion.

The Cost of Small-pox Patients.

The Kidderminster Board of Guardians has been much disturbed by a bill presented to them for the care of two small-pox patients. Two tramps were attacked with the disease and were sent off to be treated at the Borough Infectious Hospital. In the course of time an account was sent in to the Guardians by the Health Committee, who demanded £27 10s., at the rate of four guineas per week for each patient. On the Board demurring this charge was reduced to three guineas weekly, but several members insisted that half that sum, or thirty shillings, was ample payment. The chairman pointed out that on a previous occasion a case of small-pox treated at the workhouse cost there £30. Their population was 500, and isolation would have to take place in a dangerously exposed shed, besides entailing a special nurse. Eventually it was decided to pay the bill, and immediately afterwards three scarlet fever patients were sent off to the Borough Hospital. Four guineas a week certainly seems an excessive price to pay for the maintenance of a pauper patient, even when suffering from small-pox. It was stated that private patients had to pay more than that sum.

The Congress of the British Institute of Public Health.

The Lord Mayor has issued a circular letter to the sanitary authorities throughout the Kingdom intimating that the Annual Congress of the British Institute of Public Health will be held this year in London, from Thursday, July 26th, to Tuesday, July 31st, both inclusive. The Congress will be arranged in five sections, namely:—(*a*) Preventive Medicine. (*b*) Chemistry and Climatology. (*c*) Engineering and Building Construction. (*d*) Municipal and Parliamentary. (*e*) Naval and Military Hygiene. Moreover, the present position and requirements of sanitary legislation will be specially considered, and the subjects dealt with will be so grouped as to admit of convenient consideration, and the opinions of the Congress will be so formulated and recorded as to render them serviceable in strengthening the hands of local sanitary authorities and others, as well as to favourably direct the course of future sanitary legislation and administration.

Small-pox in a Lunatic Asylum.

It is to be feared that not a few of our large lunatic asylums are without adequate arrangements for the isolation of infectious disease. When an epidemic invades an institution thus imperfectly equipped it is likely to play havoc among the inmates. Something of the kind appeared to have taken place at the Essex County Asylum, where the occurrence of an alarming outbreak of small-pox has been reported. There are 1,400 patients under treatment in this place, which is said to have no proper means of isolation. The disease has hitherto been confined to the attendants and patients on the male side, and 8 deaths have occurred out of 38 cases. The fact of attendants having been attacked points to the necessity of inquiry into the medical inspection of applicants as regards their vaccination.

The estimate has been made that according to the latest returns rather more than 30 persons out of every 10,000 in this country are of unsound mind. Of course this does not include the anti-vivisectionists, the anti-vaccinationists, and some others!

According to the *New York Medical Record* a considerable number of cases of insanity have been observed by medical men occurring in persons who made pilgrimages to the World's Fair and became exhausted by sight-seeing and the excitement of Chicago.

The Royal College of Surgeons, England, and the New University Scheme for London.

A meeting of the Fellows of the Royal College of Surgeons of England, summoned by the Council of the College, took place on Monday last, for the purpose of considering the scheme of the New University in London, as embodied in the report of the Gresham University Commissioners. The proceedings commenced by the President, Mr. Hulke, reading a lengthy historical account of the part played by the Royal College of Physicians and Royal College of Surgeons in reference to the New University. All this was necessary in order to explain the decision at which the Royal Colleges had arrived in respect to the present Report of the Commissioners. The decision in question was as follows :—" That the delegates of the two Royal Colleges do cordially approve of the general provisions in the Report of the Gresham University Commission, particularly in so far as they relate to the said Colleges, regarding them as being in accordance with the principles which the Colleges have hitherto affirmed and accepted, and as constituting the most comprehensive and academic scheme hitherto proposed." Mr. Page moved "that the report of the Commissioners appointed to consider the Draft Charter for the proposed Gresham University in London, does in principle commend itself to this meeting of Fellows of the Royal College of Surgeons of England." There was a wonderful disproportion between the length of his resolution and the length of his speech; there was plenty of pathos in his discourse, but, if anything, the platitudes were in excess. As a member of the proposed new "reforming" society of the Royal College of Surgeons, it is quite evident that the Council has nothing to fear from him—his approval of the Council and its work, as expressed to the meeting, was almost described in affectionate terms. Mr. Godlee seconded the resolution, and after Dr. Collins had ably stated the case for his *alumnus*, the University of London, the Fellows were asked to express their opinion on the matter. About half held up their hands in favour of it, the other half abstained from voting. Mr. R. M. Craven, of Hull, then moved a resolution asking the meeting to agree to the suggestion that Diplomates of London "of good repute," and aged 65, should receive the degree of M.D. on the payment of "fifty-two pounds ten shillings." But no one having the presumption to second the resolution, the proceedings came to an end with a cordial vote of thanks to the President for his services in the chair.

We understand that the hearing of the probate case of the will of the late Mr. Gervas Taylor, of Dublin, will come off immediately after Easter. Mr. Taylor, it will be recollected, made, in October last, a codicil to his will by which he considerably reduced the bequests to the Adelaide Hospital and some other of the objects of his benevolence, and applied the money to other institutions and persons. It is suggested by the assailants of the codicil that he was, at the time, mentally incompetent to devise.

Dr. T. E. Thorpe, Professor at the Royal College of Science, London, and Examiner in Chemistry to the Department of Science and Art at South Kensington, has been appointed Chief of the Chemical Laboratory at Somerset House, in succession to Mr. Bell. As the appointment carries with it a salary of £1,500, it is expected that Dr. Thorpe will resign his other posts.

The Post-Graduate Course Lecture at the West London Hospital will be delivered to-day (Wednesday) at 5 p.m., by Mr. L. A. Bidwell. The subject will be "Lupus," and after the lecture several cases, treated by free excision combined with skin-grafting, will be shown. Sections of lupus, and of the new skin formed from Thiersch's grafts, will be exhibited under the microscope.

A question as to the legality of the ruling in a recent case of a medical man keeping a lunatic in an unlicensed house, for gain, was raised in the House of Commons on Monday, and the Home Secretary promised an investigation.

By the will of Mr. Henry Boys, who died on Friday last, the medical and other charities of Walsall and Wolverhampton come in for legacies amounting to £20,000.

During the construction of the Manchester Ship Canal 150 workmen were killed; 50 lost their lives over the construction of Tilbury Docks; and 500 in the erection of the Chicago exhibition buildings.

The date of the ordinary meeting of the Clinical Society, clashing this week with Good Friday, the meeting is postponed until Friday, March 30th, at 8.30 p.m.

Mr. W. R. Salmon, M.R.C.S., of Cowbridge, Pontypool, the oldest member of the Royal College of Surgeons, England, completed his 104th year on Friday last.

Mr. Hopwood, M.P., has given his annual notice of a Bill in Parliament for the total abolition of Compulsory Vaccination.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Glasgow University Court.—Glasgow University Court, with regard to the teaching of operative surgery to women students, have approved of the institution of a separate class, to be conducted by Professor Macewen's assistant in the recess during March and April.

Reunion of Glasgow University Graduates.—A dinner of Gilmorehill graduates of the year 1888, for which nearly 200 intimations have been issued, is to take place in the Windsor Hotel, Glasgow, on the evening of Thursday, 29th inst.

The Human Voice.—Dr. McIntyre, on the evening of the 13th inst., delivered an interesting and instructive lecture on "The Human Voice," particularly in its relation to singing, to the members of the Society of Musicians, Glasgow. The lecture was illustrated by numerous drawings, and also by enlarged sketches of the vocal organs as seen when put upon the screen by the use of the limelight.

Glasgow University Medico-Chirurgical Society.—At the annual business meeting held on the 16th inst. the following office-bearers were elected :—Honorary President: Hector C. Cameron, M.D. President: James F. Gemmell, M.A. Senior Vice-President: W. H. Lang. Junior Vice-President: A. Young, B.Sc. Corresponding Secretary: J. Eric Wilson, The Union. Minute Secretary: S. Sloan. Treasurer: Joshua Ferguson, M.A. Librarian: A. B. Anderson.

Habitual Drunkards — Conference in Glasgow.—A Conference convened under the auspices of the Committee on Petty Criminals and Vagrants of the Association for Improving the Condition of the People was held on the 14th inst. for the purpose of considering a proposal for the amendment of the Habitual Drunkards Act. The Chairman remarked that it was necessary that pressure should be brought to bear upon the Government so that a matter which was of such urgent importance should be allowed to remain no longer on its present footing. Professor W. T. Gairdner moved the following resolution :—"That your memorialists desire to express their general concurrence in the recommendations contained in the report (dated April 22nd, 1893) of the Departmental Committee appointed to inquire into the best mode of dealing with habitual drunkards, and are of opinion that it is desirable that the provisions of the Inebriates Act of 1879 and 1883 should be supplemented and extended by further legislation, based upon the recommendations of the Committee, with the view of making persons coming within the definition of habitual drunkards in these Acts amenable to the jurisdiction of justices, and that (subject to such safeguards as may be deemed necessary) justices should be empowered to send such persons for a limited term without their own consent to authorised retreats established for their protection and reformation, where work would be provided for them. Your memorialists have heard with much satisfaction that you have expressed your desire to bring in a bill during the next session of Parliament to give effect generally to these recommendations, and they earnestly pray you to introduce such measure into the House of Commons at the earliest possible date." In speaking to the resolution Dr. Gairdner said he should have no hesitation whatever in so adjusting the law that every drunkard in the community, habitual or not, would feel that his drunkenness was an offence against society, and that the multiplication of instances of drunkenness, even though the drunkard did nothing else but get drunk, was enough to bring him into collision with the law, but the present state of the legal arrangements with regard to drunkenness was to him an inconsistency which it was the duty of society to remove. He would like that the law should be made automatic.

Presentation to Dr. Ritchie.—Dr. A. Ritchie, who has served the Community of Pollokshaws in its municipal affairs for seventeen years, of which time he was ten years Provost, has been presented with an address in a silver casket and a deposit receipt for £100, which he intends handing over as a nucleus to a fund for forming a branch of the Queen Victoria Institute of Nurses.

◆

MEDICAL SOCIETY OF LONDON.

At the meeting on Monday evening last (March 19th) the new President, Sir William Dalby, took the chair, and votes of thanks were accorded to the retiring officers of the society. After this ceremony Dr. Wethered read a paper on "The Diagnosis of Diphtheria by Bacteriological Investigation." He had examined 26 cases of diphtheria, in 15 of which he had met with the Klebs and Lœffler bacillus, and 16 cases of follicular tonsillitis. He proposes shortly to continue his researches from a different point of view. So far, his observations bore on the morphological characters of the bacillus. He hopes to show that the recognition of the specific bacillus may prove a valuable aid in establishing the differential diagnosis between diphtheria and follicular tonsillitis, for in none of the latter did he come across any bacillus that could be mistaken for the diphtheria bacillus.

Dr. Ralfe read a paper giving the results of a series of observation carried out on patients suffering from various forms of nephritis under a milk diet. Briefly summarised he found that a milk diet is most markedly beneficial in acute nephritis, its effects being to increase the excretion of urine and the amount of solids and urea, the amount of albumen undergoing a corresponding diminution. In the chronic cases the effects on the urinary secretion were less marked, and if uræmic symptoms were threatening, the effect of a milk diet might be to increase the tendency.

Dr. Hale White referred to some investigations of his own on this subject, but his cases were all of the chronic form. He agreed in the main with the author's conclusions and observed that rather than condemn all patients with chronic nephritis to an exclusively milk diet, he would prefer not to order it at all.

Dr. Solomon Smith suggested that the milk might not be digested, in which case, not only would it not produce the usual effects, but it would virtually be a process of slow starvation.

Dr. Kelson mentioned some cases in which the addition of eggs to the dietary caused disastrous results, two of the patients dying.

Dr. Shuttleworth asked whether the milk of other animals gave the same results, and as to the precise method of analysing the urine.

Dr. Ralfe insisted on the necessity of filtering the urine before estimating the deposit of albumen, and he explained the steps of his analyses. He pointed out in conclusion that in chronic cases a milk diet was often not well borne, and that a more solid, but not a more stimulating, diet might advantageously be given in such cases.

◆

LATEST ARRANGEMENTS FOR THE CONGRESS AT ROME.

Whilst at press we received the following official record from the Secretary-General in Rome, and this may be taken by those of our readers who intend taking part in the International Congress as containing the latest arrangements in connection therewith :—

The Congress Week.

Wednesday, 28th March.—At 10 o'clock: Inauguration of the International Medico-Hygienical. At 2.30 p.m.: Reception of the Members of the Congress and their ladies in the Exhibition Palace Via Nazionale.

Thursday, 29th March.—At 10 o'clock: Inauguration of the Congress in the presence of their Majesties, the King and Queen of Italy, at the Costanzi Theatre. General Assembly of the Members of the Congress for the election of President. At 3 p.m.: Reunion of the Sections for the election of Presidents and Officers of Sections. At 9 p.m.: Illumination of the Platea Archeologica.

Friday, 30th March.—From 8 a.m. to 3 p.m.: Sittings of the Sections. At 4 o'clock: General Sitting, Conferences. At 9 o'clock: Gala at the Costanzi Theatre.

Saturday, 31st March.—From 8 to 3 o'clock: Sittings of the Sections. At 4 o'clock: Sittings of full Congress.

Sunday, 1st April.—Left free for Excursions.

Monday, 2nd April.—From 8 to 3 o'clock: Sittings of the Congress. At 4 o'clock: Sittings of full Congress—Conferences. At 9 o'clock: Reception to the Capitol, reserved to Members of the Congress and their ladies.

Tuesday, 3rd April.—From 8 to 3 o'clock: Sittings of the Sections. At 4 o'clock: Sittings of the full Congress—Conferences.

Wednesday, 4th April.—From 8 to 3 o'clock: Sittings of the Congress. At 4 o'clock: Sittings of the full Congress—Conferences. At 7 o'clock: Banquet Sections.

Thursday, 5th April.—At 9 o'clock: Sittings of the full Congress—Close of same. At 12 o'clock: Lunch at the Terme of Caracalla. At 4 o'clock: Corso des Fleurs, the Moccoletti.

The above itinerary of the Congress week may be slightly altered by eventual contingencies: such alterations will be published in time. It may be as well to remind intending members that they must procure tickets for the banquet beforehand of the Secretaries. The following is the Executive Staff:—Prof. E. Maragliano, Secretary General; Prof. L. Lucatello, Vice-Secretary General; Dott. F. Mariana, Secretary of the Executive Committee; Dott. A. Crotto, Chief of the Secretaryship Offices; Prof. E. Pagliani, M.D., Treasurer; Comm. G. Ferrando, Manager.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

THE NEW FORM OF OATH.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You have done good service in giving your readers (Med. Press, May 7th) the full text of the Oaths Act, 1888. But I fear that you will have to add to this by giving the form of words which the Act does not give.

To-day I was called before the Grand Jury at the Assizes now sitting. When the book was handed to me by the grand juror, whose duty it was to administer the oath, I claimed to swear with uplifted hand. He asked me if I would affirm, and when I answered no, he said he did not know the form of oath I meant. Fortunately I did, and so raising my hand as high as my head I repeated, "I swear by Almighty God that the evidence I shall give the Grand Jury shall be the truth, the whole truth, and nothing but the truth."

The circular sent by Mr. Asquith to coroners and justices' clerks ought certainly to have been sent to sheriffs, under sheriffs, and their officers, to be passed on to their successors. For grand jurors perform all their functions unassisted by any official except the police officer who sends in the witnesses.

The form used at our police court is: "I swear by Almighty God that the evidence I shall give touching this charge shall be the truth, the whole truth, and nothing but the truth."

The form used by our coroner is: "I swear by Almighty God, and as I shall answer to God at the Great Day of Judgment, that the evidence which I shall give to this inquest on behalf of our Sovereign Lady the Queen touching the death of ——— shall be the truth, the whole truth, and nothing but the truth."

I need not give the form used in the higher courts, as it is well known to all judges' clerks, and raising the right hand is sufficient to show them that the witness claims this form of oath.

Personally, I have the greatest dislike to be singular or to give anyone the slightest trouble or inconvenience, and no doubt these feelings are shared by the majority of medical witnesses. But, as soon as all the officials who have to administer oaths have ceased to be ignorant of what they ought to know, and the sooner the better, there will be an end of trouble or inconvenience.

The new form is as lawful as the older one. Surely it is more honest to use it than to make a pretence of kissing the book. Is it wise to wait until infection by means of the book has been proved by actual experiment?

I am, Sir, yours, &c.,
Fred. W. Lowndes.
Liverpool, 12th March, 1894.

◆

A CASE OF BELLADONNA POISONING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—On March the 6th, I saw Miss C—, a young lady, æt. 18, who twenty minutes previously had swallowed about an ounce of a liniment composed of three parts of liniment belladonna and one part of sulphuric ether, prescribed for an attack of sciatica from which she was suffering. When I saw her she was delirious, rigid, pupils dilated to their fullest extent, the eyes bright and prominent. The pulse was feeble and intermittent, skin cold and dry, constantly moaning and vomiting. The vomited matter appeared to be gastric fluid tinged with the liniment, of which it smelt strongly. I at once gave her a subcutaneous injection of one-third of a grain of sulphate of morphia combined with 1-100 of a grain of digitalin. About half-an-hour after this the efforts at vomiting became less frequent and the pupils showing a tendency to commence contracting, I got her to swallow a small quantity of warm milk. Shortly after she vomited this, smelling strongly of the liniment. I now gave her a dose of a mixture composed of tinct. opii, ♏v., liquor ammon. aromat. ♏xx, mag. carb. gr. x to the ounce, which I ordered to be repeated every hour. From this forward recovery was uninterrupted, and to-day, March 11th, she is fairly well, though too weak to leave her bed. She had suppression of urine for 24 hours.

When the pupils had become normally sensitive to light the secretion was restored. Miss C— says she was conscious all through, and though she could not control her speech, knew what she said and did. I did not think it necessary to use the stomach pump as the vomiting was doing the needful. No doubt the digitalin did good, as after its use the pulse became stronger and gradually less frequent. For some days there was soreness of the throat and difficulty in swallowing.

I am, Sir, yours, &c.,
William Donovan, M.D.

◆

THE FLAP-SPLITTING OPERATION (COLLIS'S).

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In Mr. Tait's reply to my letter on the above subject he states I do him "scant justice" whatever that means?

I never wished in the slightest degree to detract from the value of his application of the flap-spitting operation to perinæorraphy; and there is no modern surgeon in my speciality I have a greater respect for, but as Mr. Tait states that he immediately "wrote a letter to the journals pointing out the fact," may I venture to ask him what journals he alludes to?

So far as my memory serves me he wrote *one* "disclaimer" and *one only* to the *Dublin Journal of Medical Sciences* (published monthly I may remark, and having only a comparatively small circulation) not at all likely to be widely read either in England or America where Mr. Tait's operation of flap-splitting had already been published far and wide.

If Mr. Tait was "delighted to render a tribute to one of his most esteemed friends" (Mr. Maurice Collis) surely the disclaimer would have appeared in either of the leading journals, *The Lancet*, *British Medical Journal*, or The Medical Press.

I am, Sir, yours, &c.,
Cheltenham, Alexander Duke.
March 16th.

◆

THE STATUS OF ASYLUM MEDICAL OFFICERS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—During a short residence in a minor medical asylum post, I was once privileged to see somewhat behind the scenes, and may perhaps be allowed to make a few comments on the able leader which appeared in your issue of the 14th. Official life in the asylum, as presented to my observation, was indeed a tangled drama. The superintendent was a kindly and scientific man, but weak and vacillating outside his professional duties. The senior medical officer, a man of extensive acquirements, lived for his profession alone. After passing the best years of his life in earnest work he was fast drifting into the melancholy and hopeless state of the "senior resident who will never become a superintendent." Why? Because the system is carefully constructed to scotch its best men, to rob them of their originality, to sap their energies, and then to cut them adrift when they have at length succumbed to their bitterness. The two remaining residents in the asylum of which I speak may be dismissed shortly. Both were intellectually far below the level of the senior officers. One of them was sharp enough to make the most of the superintendent's good-natured weakness, and through him to toady the guardians, and doubtless his reward will in a few years be the coveted promotion. The other was a man of good instincts but of little judgment, so that he acted habitually from prejudice rather than from reason.

Let me advise all who contemplate entering this service to turn to any sort of drudgery in preference. The outlook in lunacy is as bad as it can well be. Nor is it likely to improve until the matter is taken vigorously in hand by the Local Government Board and the medical officership put on a proper basis as to pay, promotion, and pension. Meanwhile, many a good intellect and many a fair hope lies wrecked in the shoals of the asylum medical service.

I am, Sir, yours, &c.,
Fiat Justitia.

Literature.

BASTIAN ON HYSTERICAL PARALYSIS (a).

The nucleus of this work was published in the *Lancet* in the form of four lectures. The subject is a most important one, and to the general practitioner in particular it conveys advice and caution that is well justified by the experience of the author and that of all neurologists. As Dr. Bastian observes, "It may be safely said that the more slender and insecure is the practitioner's knowledge of nervous diseases, the more prone is he to regard what may be to him strange or puzzling cases, as instances of 'hysterical paralysis.'" The writer guards on every side against hasty diagnosis, and takes pains to discriminate every point with precision. Thus he eliminates emotional weakness of certain nervous patients from a diagnosis of hysteria, and emphasises the fact that restitution of function has been known to occur in cases of experimental section of the spinal cord in monkeys. In short, he would impress on his readers this important truth that speedy recovery in obscure cases may not indicate functional disease, and that tardy recovery or imperfect recovery need not indicate organic disease. The difficulties of localisation are next dealt with, and the problems and theories of the pathology of functional paralysis are afterwards stated and discussed with clearness and suggestiveness that helps the reader considerably. The two possible explanations are (1) imperfect blood supply, and (2) primary nutritive failure in the nerve elements themselves. Much can be said on both sides, and as functional paralysis exhibits a variety of symptoms, and one case cannot always be classed with another in respect to apparent cause, these two explanations may both have value, and the two causes operate separately or in some instances in concert. One important truth laid down here is that the activity of nervous elements varies in different individuals, and that the standard of nutrition may become degraded locally at times in some individuals. These facts, especially the latter, are important as bearing on the question of local weakness, *e.g.*, of facial expression, which may be mere expressions of neurasthenias; and which are sometimes hastily assumed to be premonitory of the onset of organic disease. The cases related are grouped in two great divisions: (1) Cases of Functional Paralysis of Cerebral Type; and (2) Cases of Spinal Type. Under the first division he leads off with a remarkable case of kinæsthesia and monoplegia, the result of injury in which the clavicle was fractured. This case Dr Bastian views in the light of his own theory that the so-called motor areas do not exist as stated by Ferrier and others, but that the so-called motor area is the *locale* of a special class of sensory centres—namely those registering kinæsthetic (sense of movement) impressions. This interpretation is now accepted by Victor Horsley, and the author states it with clearness and point. Space will not permit us to enlarge further. There is here a well-arranged system of clinical facts bearing on the subject of functional paralysis which is a valuable and authoritative contribution to the literature of the subject. There are also three appendices on the muscular sense, on the neural process underlying attention and volition, and on double representations of touch and common sensibility in the cerebral hemispheres. The work altogether is well considered, eminently practical, and certainly worth the thoughtful study of the neurologist and general practitioner.

New Inventions.

THE HERCULES HORSE ACTION SADDLE.

This most ingenious machine is intended to supply a substitute for riding on horseback. It consists of a broad and comfortable saddle mounted on a kind of compound box in which are concealed several layers of strong springs. The saddle rests on a fore and aft axle which plays up and down in a couple of vertical slots. Its action is simple. The rider first determines the exact range of up and down motion he may require by tightening a couple of adjustable clamps. He then mounts in the ordinary way and starts on his ride by pressing his feet against a pair of side stirrup boards. The pace, from a gentle amble to a hard gallop, can be regulated at the will of the rider. From actual trial we can testify that the imitation of the various paces of the horse is of a realistic nature. Further, from subsequent symptoms we can assert that a ride in the Hercules saddle calls into action the same sets of muscles as those brought into play on horseback. As everyone knows, horse riding, although a most desirable form of exercise, is *caviare* to the general public on account of its costliness. The Hercules horse saddle, however, meets that difficulty by offering a good practical substitute at a price which brings it within the reach of all. Medical men, therefore, need no longer be in doubt where to apply if they wish to prescribe an equivalent for horse exercise. Dr. Fleming, the well-known veterinary authority, speaks enthusiastically of the cleverness and merits of this machine. This really remarkable mechanical invention is placed in the market by Messrs. Vigor, of 21 Baker St., Portman Sq., London. We are informed that the proprietors will be pleased to explain the details of the Hercules saddle to any medical men who may care to call and inspect it at their premises. It should be added that the apparatus can be instantaneously adapted as a side-saddle for ladies' use.

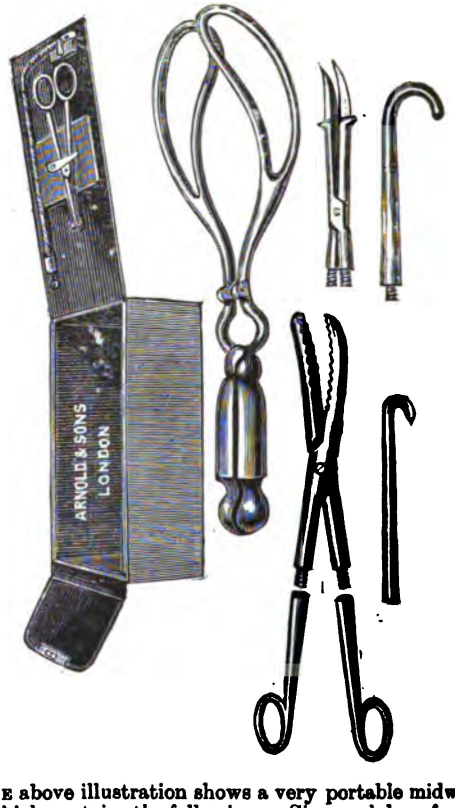
THE "COMPACTUM" MIDWIFERY CASE.



The above illustration shows a very portable midwifery set which contains the following:—Simpson's long forceps, (folding); craniotomy forceps and perforator to fit into the same handle; blunt hook and crotchet (jointed); framing scissors and female catheter. All the instruments are nickel-plated and fit into a morocco leather case measuring 8½ × 3½ × 3½ in. The makers are Arnold and Sons, of West Smithfield, London.

(a) "Hysterical or Functional Paralysis." By H. Charlton Bastian, M.D. London: H. K. Lewis. 1893.

Medical News.

Irish Medical Schools' and Graduates' Association.

The annual general meeting was held on Saturday last, March 17th, under the presidency of Dr. Richard Heath, when the election of the Officers and Council for the ensuing year resulted as follows:—President: Richard Heath, M.D. President-elect: Henry Heygate Evatt Phillips, M.D. Vice-Presidents: Alexander Macalister, M.D., F.R.S., Richard Fegan, M.D., George Hugh Kidd, M.D., Thomas Gilbart-Smith, M.D. Honorary Treasurer: Charles Wells, M.D. Council: Phineas S. Abraham, M.D., William Barter, M.D., Campbell Boyd, Richard Maitland Coffin, James Davison, M.D., Thomas Michael Dolan, J.P., M.D., Henry Grier, Surgeon-Major A.M.S., John Hadden, M.D., Charles Henry Hartt, Archibald Hamilton Jacob, M.D., John Joseph Lough, M.D., George Stoker, Richard Jocelyn Swan, Francis John Waring, M.D., William Dakin Waterhouse, LL.D. Honorary Auditors: William Henry Bourke, M.D., and John Joseph Redfern, M.D. All unanimously elected.

The Dinner.

After the close of the business meeting, the annual dinner was held at the Café Monico, and from every point of view was perhaps the most successful of all the festive gatherings of the Association since its establishment. Upwards of one hundred members and guests sat down to the repast. The speeches were of the most felicitous character, the music of an attractive and enjoyable kind, the hon. secs. and the dinner committee were most assiduous in their attention to the visitors, and last, though not least, of the contributory causes to the end attained may be mentioned the unobtrusive geniality of the president, Dr. Heath. He appeared content to subjugate his own personality in making the shortest of possible speeches, in order to give free scope to the post-prandial oratory of his guests. Among these may be specially mentioned Sir Raymond West, K.C.I.E., Mr. R. O'Lane, Q.C., Mr. Robert Anderson, LL.D., and Inspector-General Lloyd, R.N. The other speakers were members of the Association, and were Dr. H. W. Maunsell, Surgeon-Major Grier, R.N., Dr. Mapother, Surgeon-Major Carte, and Dr. Cagney, each of whom acquitted himself of his allotted *rôle* most creditably. It should be added that the latter gentleman paid a well-deserved and eloquent tribute to the memory of their late *confrère*, Surgeon-Major Parke, of African fame, at the same time making an earnest appeal to the members present each to contribute something to the memorial about to be erected in Dublin, adding that Signor Nachez, the eminent violinist, who had favoured the company that evening with some exquisite music, had volunteered his services for a concert in aid of this object, which Dr. Cagney himself undertook to arrange. The Association now numbers 719 members, and there is no reason, as the President remarked, why even this satisfactory number should not be doubled in process of time.

The Proposed Veterinary College for Ireland.

The movement for the establishment of a College, for which, it will be recollected, the Chief Secretary promised £15,000, has assumed a practical shape, and, at a meeting of the promoters last week, the draft charter was considered and approved. The Royal Dublin Society is to send delegates to the Board of Governors, and the Board of National Education has already named representatives. Meanwhile, certain of the veterinary surgeons have taken umbrage because they think that they have not been given a sufficiently important part in the organisation, and they have written to the newspapers denouncing the movement. It is a pity that they should take the churlish position of looking the gift-horse in the mouth, but we hope that their abstention will not interfere with the successful realisation of the object in hand. The promoters are fortunate in finding, ready to their hand, premises very suitable for the purpose of the College, in the vacant Carmichael College, which, we believe, the College of Surgeons would be glad to sell for the purpose. These buildings cost the Carmichael proprietors £8,600, and were, a couple of years ago, valued by an expert at £6,150, but it is understood that the College of Surgeons, which has no use for them, would accept £3,500 for them. It would cost the promoters nearly three times that amount to build suitable premises, and, in any case, there would be much difficulty in procuring a suitable site.

Dispensing Prescriptions in Ireland.

It will be recollected that recently we called attention to the fact that the Irish College of Physicians had abrogated the rule which prohibited their Licentiates from compounding medicines. The Pharmaceutical Society thereupon referred to its Law Committee to consider whether the rights of Irish pharmaceutists and apothecaries have been thereby infringed, and a letter has been received from the College of Physicians to the effect that "the amendment of the rule conferred no rights on the Licentiates which they did not previously possess." A very judicious reply.

The Countess of Dufferin's Fund, Calcutta.

The ninth annual report of the Countess of Dufferin's Fund has just reached us, and from which we gather that the record of the year is one of steady progress. There has been, we find, an increase in the number of lady doctors, of assistant surgeons, and of hospital assistants. Additions have been made to the number of scholarships for women; their value has also been raised, with the special object of attracting Hindoo and Mahomedan students to the work. The number of female students in the various schools and colleges of medicine shows some diminution. This, however, is a matter of no moment, as numbers are expected to fluctuate year by year in all our schools of medicine. But what is far more important to our Indian population is that several new hospitals have opened during the year, and many more are either under construction or will shortly be commenced. The number of patients treated shows a very considerable increase, and there is evidence that the advantages offered by the Lady Dufferin Association are becoming more and more appreciated by that large class for whom they are especially intended, the Purdar women of India.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 34, Bombay 37, Madras —, Paris 24, Brussels 21, Amsterdam 19, Rotterdam 20, The Hague 19, Copenhagen 20, Stockholm 18, Christiania 19, St. Petersburg 28, Moscow 34, Berlin 17, Hamburg 18, Dresden 20, Breslau 27, Munich 24, Vienna 28, Prague 36, Buda-Pesth 24, Trieste 45, Rome 24, Turin 26, Venice 26, Cairo 49, Alexandria 51, New York 23, Brooklyn 19, Philadelphia 22, New Orleans 28.

Vital Statistics.

The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 19·9 per 1,000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year, and were—Birkenhead 20, Birmingham 17, Blackburn 23, Bolton 20, Bradford 18, Brighton 18, Bristol 20, Burnley 18, Cardiff 22, Croydon 17, Derby 16, Dublin 30, Edinburgh 18, Gateshead 14, Glasgow 22, Halifax 20, Huddersfield 11, Hull 16, Leeds 17, Leicester 19, Liverpool 25, London 20, Manchester 21, Newcastle-on-Tyne 19, Norwich 14, Nottingham 14, Oldham 18, Plymouth 22, Portsmouth 14, Preston 19, Salford 22, Sheffield 19, Sunderland 21, Swansea 20, West Ham 20, Wolverhampton 23. The highest annual death-rates were—From measles, 5·4 in Birkenhead; from scarlet fever, 1·1 in Gateshead; from whooping-cough, 2·4 in Plymouth; and from fever, 1·1 in Burnley. The death-rate from diarrhœa did not reach 1·0 per 1,000 in any of the towns. The 89 deaths from diphtheria included 53 in London, 6 in Glasgow, 5 in Manchester, 4 in Liverpool and in Cardiff, 3 in Wolverhampton, 2 in Salford, and 2 in Sheffield. Four deaths from small-pox were registered in Bradford, 3 in West Ham, 2 in Birmingham, and one death each in Bristol, Oldham, and Leeds, but not one in any other of the towns.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

A LEONINE PATIENT.

THE staff of the New York College of Veterinary Surgeons must be allowed to take the palm for a "bold" piece of surgery. The term "bold" must be taken in a different sense, however, to that with which it is usually associated in the practice of our art, inasmuch as the staff of the College was called upon to operate upon a lion. This was clearly reversing the usual order of things, because lions have always displayed a marked facility for "operating" themselves. Happily, in this instance the leonine patient was successfully made to forget what his natural predilections were by an injection of morphia. Under the influence of the morphia the operation—by the staff—was performed without difficulty. It consisted in reducing and setting a fracture of the lion's femur. Just at this interesting point, however, the narrative ceases. Nothing is said of how the porters acted who came with the stretcher and removed the lion from the operating theatre to his ward—that is to say—cage. It is to be trusted that the full notes of this interesting case will be subsequently published, giving a careful record of the lion's pulse and temperature during the progress of the treatment, without which, of course, no clinical record could be complete. A photograph, too, of the surgeon and the clinical assistant might be subjoined, showing how they looked before the treatment was begun. Of course, in the case of certain eventualities arising, the photographs would also be useful as a record of the lion's medical attendants.

SANITARIAN.—The question of the two *versus* the three-gallon flush for water-closets has passed the stage of justification, and is now being considered in the light of expediency. We have little doubt that the present vexatious restrictions will shortly be modified or abolished.

A QUACK IN COMIC OPERA.

THE following passage is taken from the new play, "Wapping Old Stairs," at the Vaudeville. It gives an amusing sketch of the smattering of science which characterises the modern medical charlatan:—

I've read Gerard and Doctor Dee, herb-dealers astrologic.
I've studied hard Histology, a subject hypnogogic.
I've also been a teacher of caliginous Psychology,
And make a special feature of Phytophagous Zoology;
I lecture, when requested, on the purifying oxidants,
I've personally tested all the better known intoxicants;
By very strict attention paid to special Scotch analysis,
I know all things worth mentioning of public-house paralysis;
Too hard no subject have I found to master that I take up!
No medicated compound, nor a plaster I can't make up.
For tho' I boast of no degree, and never went to college,
My mind is an epitome of pharmaceutic knowledge!

DR. G. M. (London).—We should certainly decline the doubtful honour of publishing a contribution written under such questionable auspices, and we are of opinion that you would be well advised in declining to give it the support of your name. If legally admissible, it would be morally indefensible.

HOME-MADE SHERRY.

THE Public Analyst for Glamorganshire gives in his last report an analysis of a British sherry which he had examined. It was found to contain no alcohol whatever, but was composed of sugar, a little essence and bisulphite of lime.

MR. S. RICHARDSON.—The necessity for telephonic communication between hospitals has been discussed in former numbers, but we are not in a position to say what steps, if any, have been taken to carry our suggestions into effect. The most efficacious plan would probably be to interest one or two individual governors in the matter.

STUDENT (London).—The scale of fees varies with some of the schools, but our correspondent will find all the information he requires in our Students' Number, issued in September last. Apply to the Publishers.

PENSATOR.—The Report of the Commission on Tuberculosis has not yet appeared, despite the anxious inquiries which have been made.

XERXES.—The names of candidates must be sent to the Pralector of whichever college you select on or before Saturday, April 7th. We would advise you to write before hand for full particulars.

LEATHER SUPPOSITORIES.

OUR genial contemporary the *Chemist and Druggist* comments upon the notion possessed by certain physicians that tannin and gelatine go well together in the following prescription:—

Acid. tannici, gr. x;
Massæ gelatinæ, q.s.
Ft. supposit.

NEMO (Belfast).—We cannot publish scurrilous correspondence of the kind you desire to place at our disposal.

L. M. P.—We have, at times, felt doubts as to our correspondent's sanity, but we have not felt at liberty to make our views known. Our duty, we take it, ends when we have consigned his incoherences to the waste-paper basket.

DR. L. V.—We have received the article, and will write you later in reference thereto.

SPES.—From inquiries we have made there do not appear to be any grounds for the allegation.

Vacancies.

Bethlem Hospital.—Two Resident Clinical Assistants. Apartments rations, and attendance provided. Applications to the Clerk, Bridewell Hospital, New Bridge Street. (See advert.)

Birmingham and Midland Free Hospital for Sick Children.—Resident Medical Officer and a Resident Surgical Officer. Salaries £70 and £50 respectively, with board, washing, and attendance. Applications and testimonials to the Secretary on or before April 4th.

Birmingham General Dispensary.—Resident Surgeon. Salary £150 per annum, with furnished rooms, attendance, &c. Applications and testimonials to the Secretary on or before April 11th.

Carnarvonshire and Anglesey Infirmary.—House Surgeon. Salary £70 per annum, with board and lodging Applications and testimonials to the Secretary on or before April 7th

County of Northumberland.—Medical Officer of Health. Salary £500 per annum and travelling expenses. Applications and testimonials to the Medical Officer on or before March 24th.

Metropolitan Hospital, Kingsland Road, N.E—House Physician, House Surgeon, and Assistant House Surgeon. Salaries £60 per annum each. Applications and testimonials to the Secretary on or before March 26th.

National Hospital for the Paralysed and Epileptic.-(Albany Memorial), Queen Square, Bloomsbury.—House Physician. Salary £100 per annum, with board and apartments. Applications and testimonials to the Secretary on or before March 31st.

Sheffield School of Medicine.—Tutor. Salary £125 per annum. Applications to the Secretary on or before April 2nd.

Suffolk General Hospital, Bury St. Edmunds.—House Surgeon. Salary £100 per annum, with board, lodging, and washing. Applications and testimonials to the Secretary on or before March 26th.

Taunton and Somerset Hospital.—Qualified Assistant House Surgeon. No salary, but board, washing, and lodging. Applications and testimonials to the House Surgeon on or before March 24th.

Appointments

AINSWORTH, H., M.R.C.S., L.R.C.P., House Surgeon to the Manchester Royal Infirmary.

BYERS, A., M.B., Ch.B.Vict, B.Sc.Lond, House Physician to the Manchester Royal Infirmary.

DOUTY, E. H., M.A., M.B., Lecturer on Midwifery in the University of Cambridge.

ECCLES, W. MCADAM, M.B., B.S.Lond., F.R.C.S.Eng., Assistant Surgeon to the City of London Truss Society.

FLETCHER, J. H., M.R.C.S., L.R.C.P., House Surgeon to the Manchester Royal Infirmary.

HICKEY, G. A., L.R.C.S., L.M.Irel., Consulting Medical Officer for the Borough of New Ross, county Wexford.

MCDOUGALL, A., M.R.C.S., L.R.C.P., House Surgeon to the Manchester Royal Infirmary.

MCKERRON, R. G., M.B., C.M., D.P.H.Aberd., Chloroformist to the Aberdeen Hospital for Sick Children.

MARSH, J. H., M.R.C.S., L.R.C.P., House Surgeon to the Manchester Royal Infirmary.

MORGAN, O. W., L.R.C.S., L.R C.P., L.M.Ed, L.F.P.S.Glasg., Visiting Surgeon to the Newport and Monmouth Infirmary.

MORGAN, J. H, M.A., F.R.C.S., Special Lecturer on Clinical Surgery at Charing Cross Hospital School.

PATERSON, D. R., M D Ed., M.R.C.P.Lond., Lecturer on Materia Medica and Pharmacy, University College of South Wales.

ROSE, G., M.B., C.M., D.P.H.Aberd., Assistant Surgeon to the Aberdeen Hospital for Sick Children.

THOMPSON, A. E., M.B., B.S., Visiting Medical Assistant to the Newcastle-on-Tyne Dispensary.

WESTMACOTT, F. H., M.R.C.S., L.R.C.P., Medical Officer to the Manchester Royal Infirmary Convalescent Hospital at Cheadle.

WILKINSON, W. A., M.B., C.M., Ch.B.Vict., House Surgeon to the Manchester Royal Infirmary.

Births.

BULLOCK.—March 16th, at Eastgate House, Warwick, the wife of Roger Bullock, M.R.C.S., of a daughter.

GARDNER.—March 15th, at Mountain Ash, Ore, Hastings, the wife of the late C. Gardner, M.R.C.S., L.R.C P., of a son.

MIDDLETON-GAVEY.—March 13th, at Lingwood, Weybridge, the wife of E. H. Middleton-Gavey, M.R.C.S.Eng., of 94 Wimpole Street, W., of a daughter.

Marriages.

PYE-SMITH—FOULGER—March 7th, at Christ Church Lancaster Gate, Philip Henry Pye-Smith, M.D, F.R.S., of Brook Street, London, W., to Emily Gertrude, youngest daughter of the late Arthur Foulger, of Chigwell Row.

ROSE—ENGLAND.—March 17th, at the Parish Church, Hampstead, F. Septimus Rose, youngest son of H. Cooper Rose. M.D., to Edith, youngest daughter of the late J. England, Esq., of Alfreton.

Deaths.

BIGGS.—March 8th, at Egmont, Dulwich Wood Park, James Strange Biggs, M.D., M.R.C.P.Lond., M.R.C S., L.S.A., aged 66.

BROXHOLM.—March 19th, at Belmont, Woodside Avenue, North Finchley, Frederick Giles Broxholm, M.D., aged 72.

DEVENISH.—March 16th, at Queenborough, Cleveland Walk, Path, Samuel W. Devenish, M.D.

PILCHER.—March 11th, at sea, near Suez, Mary, wife of Surgeon-Colonel J. G. Pilcher, Bengal Medical Service.

PRICE-JONES.—March 18th, at 7 Claremont Road, Surbiton, Helen Louise, wife of Cecil Price-Jones, M.B.Lond., after a few hours illness, aged 24.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CVIII. WEDNESDAY MARCH, 28, 1894. No. 13.

Clinical Demonstrations

By JONATHAN HUTCHINSON, F.R.S., LL.D.,

Ex-President of the Royal College of Surgeons, England, Consulting Surgeon to the London Hospital, &c.,

(*At his Clinical Museum, London.*)

ON Tuesday, February 20th, the following cases were demonstrated :—

(1) *A man, the subject of Primary and Secondary Syphilis, in whom Inoculation from his own Chancre appeared to have taken place.*—The primary sore had been present (on the prepuce) three months, and there was now a plentiful papular eruption over the trunk and limbs. The sore was indurated, but attended by considerable secretion. On the inner side of the left thigh, just below where the extremity of the prepuce touched, were three sores in a line upon a dusky and somewhat indurated base. Mr. Waren Tay, who had sent the patient, stated that the induration had been more marked a few days ago, and was already diminishing under treatment. It was quite certain that these sores (which were confluent) were no part of the secondary eruption. They were primary, and the alternative was whether they should be considered as resulting from simultaneous inoculation or from infection after the sore on the prepuce had formed. The man's own statement favoured the latter hypothesis, for he had not observed them until some time after the first sore was recognised. Their position was also very suggestive, being exactly where secretion from the penis might have touched. The next question was, should they be regarded as "soft sores," or as true chancres. Their appearance was that of the latter. The precise dates in this case were :—Infection three months ago; sore observed on the penis one month later; those on the thigh two weeks later still; and the secondary eruption a fortnight afterwards.

(2) *Chancre of the Conjunctiva.*—A man who had attended a week previously came again, in order that the diagnosis might be substantiated by showing a plentiful papular eruption which had since come out. The sore on the eye was healing, and the swelling less. There could now not be the slightest doubt that the case was one of syphilis, and as the man had a large bubo under his jaw, and no sore elsewhere, there could be equally little doubt that the conjunctival sore was an infecting chancre. It was of interest to note that the man had in the first instance been admitted into an ophthalmic hospital as a case of ulcer of cornea, where scraping had been practised. It was only when the glands enlarged that the true diagnosis was suspected. It was then found that the man had been in risk of infection, and that he had a gonorrhœa on him.

(3) *A Patient the subject of Lentigo-Melanosis.*—It was explained that under this term was meant a condition of melanotic staining of the eyelids, which had developed from freckles. The patient was a lady of sixty-two, whose portrait has already been given in Archives. The condition had been in progress for almost six years. Gradually from the coalescence of freckles and serpiginous spreading of the patch, the whole of the upper and lower lids had become involved in a coal-black stain. The conjunctiva had also become involved, and the lower half of the eyeball, as also the corresponding part of the arcus, was of a deep bistre tint. About six months ago an ulcerated malignant growth had been excised from the edge of the lid. This growth was not black, and was proved by the microscope to have a sarcomatous structure. Mr. Hutchinson stated that he had seen at least six examples of this curious malady, and that in three a malignant growth had resulted some years after the melanoid staining. The latter, in itself, showed no tendency either to ulcerate or to form a thick growth. The disease was quite distinct from the ordinary forms of melanotic sarcoma. It afforded a most interesting example of a physiological process—assuming, first, infective powers; and, lastly, tending to malignancy.

(4) *A Large Ossified Tumour of the Femur in association with Brittle Bones and Congenital Dislocation of the Radii at the Elbows.*—This was a case of extreme interest. It had been brought from Reading by Mr. Hastings Gilford, of that place. The patient was a woman of thirty. From birth she had presented peculiarities at the elbows. The head of the radius in each rested above the condyle (dislocation forwards), and was just under the skin. The olecranon was in normal relations with the humerus, but the shaft of the ulna, a little above it, presented a deep hollow as if bent. The rest of the forearm, wrist, and hand were well formed, but short. At the age of one the patient fell and broke the left femur, and during the next few years one rib and both humeri were broken in falls. At the age of twelve a very large softish swelling formed about the left femur, with much pain. She was then an in-patient at St Bartholomew's, and amputation was strongly and very properly advised. The parents, however, refused, and took her home, and after a year from the beginning the tumour ceased to grow, and became hard. At the present time the tumour involves the whole shaft of the femur, and increases the thigh to three times its normal girth. Sir James Paget, who had examined the patient before the demonstration, concurred in the opinion that it was probably an ossified enchondroma. Both tibiæ were much bent, one as the result of fracture united with overlapping. The problem was to find any bond of connection between the congenital dislocations, the childhood-fractures, and the tumour.

(5) *A Case of Severe Bromide Eruption in an Infant.*—The child was fourteen months old. Doses of bromide from two to six grains had been given every four hours for three weeks. The eruption consisted of thick tuberous papules, which had formed on the face and limbs. There were none on the trunk. Those on the legs were ulcerated, and covered with thick pus crusts. The medical man who brought the patient, stated that since leaving off the drug the eruption had still increased. This, however, was only for a few days. The skin between the tubers was, as usual, quite healthy. Some portraits, showing precisely similar conditions, were shown. In reference to the fact that the eruption had not been immediately arrested by leaving off the drug, Mr. Hutchinson remarked that a certain time must be allowed for elimination. In certain cases, however, if the drug had been used for some time, the process of morbid growth was not stopped by removal of the exciting cause, but went on to a fatal termination. In illustration of this, there were, he said, several portraits in the Museum. It

was chiefly the iodides, however, which produced these fatal cases; the bromides were seldom or never actually fatal.

(6) *A Patient in whom a most severe form of Psoriasis had been almost cured by Thyroid Feeding.*—This patient had attended a month ago to show a most severe form of psoriasis. He was then covered over trunk and limbs by psoriasis crusts so closely placed that they, although not of large size, were almost confluent. He had been entirely disabled from all employment. Much treatment had been tried, but no permanent benefit obtained. He now came to show the very remarkable results of thyroid feeding. His trunk was almost clear, and the skin soft. On his limbs some scaly patches still persisted, but they were all fading. The result of the treatment as a whole was wonderfully good. The treatment had been by a tabloid of extract three times a day. It had been carried out by Mr. Waren Tay at the London Hospital, by whom the patient had been sent.

(7) *A man, æt. 37, in whom a Rodent Ulcer had been present Six Years.*—The chief interest of this case consisted in the fact that the disease did not look at all formidable. It consisted of a patch the size of a half-crown on the cheek just above the whisker. It had been called "lupus" by most who had seen it. Attention was directed to its rolled, sinuous edge, characteristic of rodent ulcer.

[Three very similar cases in comparatively young subjects have been produced for demonstration at the Museum during the last two months. In all the same region was affected.]

(8) *A Patient the subject of General Pruriginous Dermatitis.*—This case had been diagnosed as "pruriginous lichen," and as "dermatitis herpetiformis." The patient was a man, æt. 19, who had been sent from the London Hospital by Mr. J. Hutchinson, jun. He was covered on the trunk and limbs by a papular and slightly scaly eruption, so abundant as to almost cover the whole surface. There were no vesicles, and no moist eczema. It had resisted all treatment, and been present more than two years. It had been worse in winter. Its beginning had been papules on the shoulders. There was a statement that vesicles had been present, but none had been demonstrated. Mr. Hutchinson stated that it was a type of dermatitis which he knew well, but could not name. It was, in his experience, usually incurable. He did not think that it had any close alliance with dermatitis herpetiformis. He suggested a trial of thyroid feeding.

◆

THE
PLACENTA IN ECTOPIC GESTATION
AND
ITS GROWTH AFTER THE DEATH OF THE FŒTUS.

By ALFRED S. GUBB, M.D. Paris, &c.

There are several points still imperfectly elucidated in relation to the growth and *rôle* of the placenta in cases of ectopic gestation which seem worthy of particular attention, partly because of their intrinsic interest and partly on account of the importance of their bearings on the prognosis and treatment of this curious abnormality. Adopting the view that ectopic gestation is usually, if not invariably, primarily tubal or interstitial, I shall confine my remarks mainly to these forms.

The behaviour of the placenta in these cases has during the last few years come to be recognised as a subject of special interest to gynæcologists, not only because of the difference of opinion that prevails with respect to the best manner of dealing with it, but also on account of various developmental abnormalities which tend to complicate the situation. Moreover, the great danger accruing to the patient in operations for the removal of ectopic gestation cysts is mainly due to causes connected with the subsequent behaviour of the placenta.

The shape and structure of the ectopic placenta vary within wide limits, owing to circumstances connected with its unnatural situation. According to Dr. Herman ("Obstetrical Transactions," vol. xxiv.), two varieties are met with—one, thin and spread out, having very extensive attachments, and the other, a solid, thick lump, denser and closer in structure than a normal placenta, looking not unlike hepatised lung. In the latter kind the vascular connection is much less extensive and intimate, and the placenta can be removed without great fear of consequences. It is surmised that this change into a fleshy mass takes place after the death of the fœtus, but I shall have occasion to discuss this question further in reference to the possibility of actual growth.

In the classical case recorded by Dr. James Braithwaite ("Obstetrical Transactions," vol. xxviii.) the placenta had spread itself out on the peritoneal surface of the uterus. He left it alone for obvious reasons, and he supposed that it ultimately underwent absorption (?).

In a case brought before the British Gynæcological Society by Mr. Howard Barrett, in which the patient had succumbed to hæmorrhage consecutive to the rupture of a five months' ectopic (ovarian?) gestation (*British Gynæcological Journal*, Nov. 1891), he states that at the autopsy no true placenta was found, but the interior of the cyst wall showed three or four large patches of purple, and apparently placental, tissue with sharply defined margins. Two of these patches had slight vascular connection with each other, while the others were quite isolated. One patch was situated at the extremity of the cyst where the ulceration had commenced, and the hæmorrhage had proceeded from the laying open of its vessels. It was not with this patch that the cord was connected, but with a large one in the centre of the long axis of the cyst. These patches were not appreciably raised above the surface, but the structure dipped down into the cyst wall.

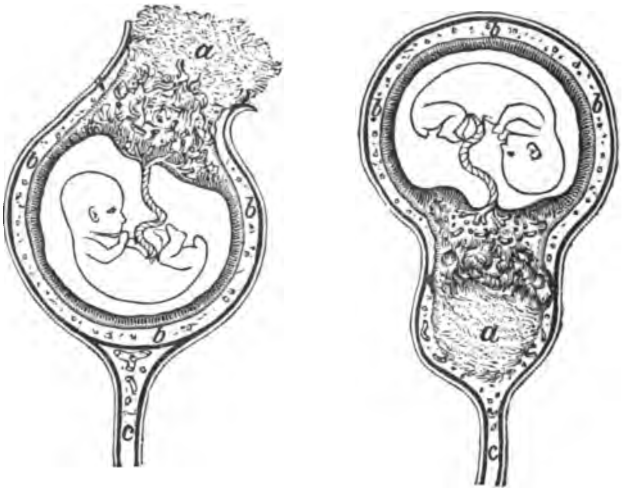
Let us however pass in review the causes which are at work and tend to modify the structure of the ectopic placenta. After primary rupture of the tube the embryo and placenta (when the development is sufficiently advanced) gradually occupies a sac formed by the expanded tube and separated layers of the broad ligament, the floor of the space being formed by connective tissue and the levator ani muscle. The ultimate effects of this gradual dislocation of the embryo and placenta depend mainly upon the original position of the placenta. Dr. Berry Hart points out that if the embryo lies above the placenta the latter becomes depressed downwards between the layers of the mesometrium until it is arrested by the pelvic floor. If, on the contrary, the embryo lies below the placenta the embryo and its membranes burrow between the layers of the mesometrium and the placenta becomes pushed up by the growing embryo until it lies high in the abdomen. When the placenta is displaced into the mesometric tissue (a gradual process) the placental tissue is exposed to very serious damage. The villi become less perfect in contour, blood extravasation is present and the decidual cells are fewer in number and less regular. The result of Dr. Berry Hart's observations led him to conclude that the displacement of the placenta from mucous membrane to connective tissue gradually reduces the placenta to a mass of compressed villi, the serotina being destroyed and replaced by organised blood clot. The least damage is sustained by the placenta when the embryo is situated above it, because under such circumstances it undergoes the minimum amount of displacement. It is of the utmost importance to correctly appreciate the structural alterations which occur in the placenta consequent upon these remarkable displacements as they exert a great influence upon the subsequent history of the pregnancy, placing the life of the mother in peril and being in most cases destructive to the life of the fœtus. The constant tension to which the peritoneum covering the gestation sac is subject may at any time cause it to yield and so lead to partial detachment of the placenta, and, as a consequence, give rise to severe hæmorrhage either into the sac enclosed by the layer of the broad ligament or into the peritoneal cavity. A woman with a broad ligament pregnancy with the placenta situated above the fœtus runs a far greater risk of losing her life than she would even in a case of placenta prævia.

When the progress of the fertilised ovum along the Fallopian tube is arrested the walls of the oviduct undergo more or less thickening and vascularisation. The tube becomes distended and the chorionic villi of the fœtal sac penetrate the substance of the mucous membrane down to the muscular layer, which, although absolutely increased in amount, is locally thinned out, but, according to Leopold, the villi never break through the walls of the maternal vessels. The vascularity of the walls of the tubes and of the broad ligaments in which they lie is greatly increased. In all forms of ectopic gestation the connection between the ovum and the abnormal surface upon which it is grafted is established by a vital adhesion between the chorionic villi and the tissues with which they come into contact. This has been demonstrated by Braxton Hicks and Engelmann. As there is here an entire absence of decidua the process differs from that met with in the uterus where the serotina fulfils an important and active part in connecting the ovular and maternal tissues by proliferating cell activity. At the same time, according to Bland Sutton, the tubal mucous membrane plays a very insignificant part in this form of ectopic gestation, the tubal placenta being mainly, if not entirely, derived from the fœtal tissues.

Ultimately the continued development of the ovum within the tube invariably determines laceration of its walls, due probably to the fact that the excavations resulting from the ingrowth of the chorionic villi weaken their powers of resistance to the continuous and increasing strain. Moreover, this weakened portion of the duct wall is immobilised by the adherent placenta and is unable to expand in proportion to the rest of the tube wall. As the tubal sac dilates it drags upon the thinned placental site and a tear results. The ovum escapes from the tube, its ultimate destination (whether the peritoneal cavity or the potential cavity of the broad ligament) being determined by the relationship in point of position between the tear and the folds of peritoneum investing the tube.

As Mr. Tait long since pointed out, if the rupture occur immediately opposite the folds of peritoneum which come into apposition to form a sort of mesentery, after enveloping the tubes, the layers will be violently separated and the blood extravasates into the broad ligament. If the rupture occur at any other part of the circumference it opens directly into the peritoneum. As, however, my subject is the placenta I need not pursue further this interesting topic.

The escape of the ovum may be followed immediately by detachment of the placenta, and symptoms of profuse internal hæmorrhage. In cases where the hæmorrhage does not prove immediately fatal, either because the rupture is only partial or because the blood being effused between the folds of the broad ligament there is a mechanical obstacle to a continuous and fatal outpour, neither the placenta nor the fœtus may be destroyed. Cases are reported by Mr. Tait and others in which a portion of the placenta covered with freshly detached chorionic villi has been seen protruding through the laceration. One such case is that recorded by Mr. Tait in which the tubal sac had evidently ruptured some time before, and the fœtus had gone on growing among the intestines to which, and to the omentum, the placenta had contracted secondary adhesions. In this specimen the omentum has still adhering to it fragments of chorionic villi. This case was shown at the Birmingham meeting of the British Medical Association, in July, 1890, and I have had an opportunity of personally examining the specimen. The fœtus measured about six inches in length, and an examination of the lacerated tube showed that there had been previous ruptures with associated hæmorrhage, but insufficient to kill the fœtus which was being developed among the intestines to which the placenta had evidently contracted fresh adhesions. This fact is interesting because it may serve to explain the appearances which are still held by many observers to prove the existence of primary abdominal pregnancy. There does not seem any *a priori* reason for denying the possibility of a partially detached placenta contracting fresh adhesions. Indeed the continued development of the fœtus which not unfrequently survives the rupture is *prima facie* evidence of the ability of the partially dislocated placenta to seek pastures new. In some cases the fœtus alone may escape through the laceration in the tube walls, leaving the placenta *in situ* where, in the course of further development, it protrudes and engrafts itself on to adjacent surfaces.



1.—Diagrammatic section of Fallopian tube showing the direction of the rupture (1) into the peritoneal cavity, and (2) between the layers of the broad ligament.

Alternatively, after the death of the fœtus the placenta may (1) become devascularised and disappear by absorption (?)

(2) It may become hepatised with subsequent atrophy and even calcification, or

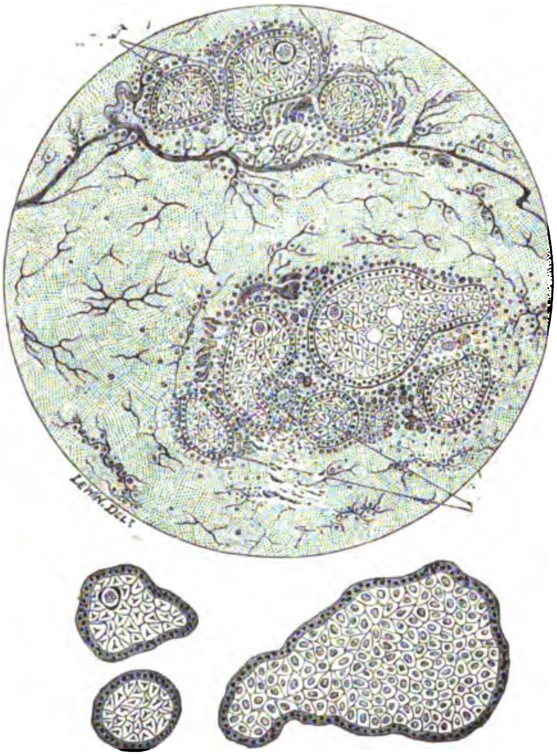
(3) It may continue to grow.

A review of the literature of the subject leads one to the conclusion that the usual sequence of events in advanced cases is as follows :—

After the death of the fœtus, from whatever cause, the blood supply of the placenta is gradually reduced and its structure consequently undergoes fatty degeneration. Extravasations of blood take place into its tissues and it becomes hepatised. If sufficient time elapses the blood-clot may undergo more or less organisation. The particular point to bear in mind is that within from six to twelve weeks of the death of the fœtus the vascular supply of the placenta is so far reduced that its removal may usually be attempted without material risk of hæmorrhage to the patient.

This train of reasoning has led to the practice of postponing operative interferences until sufficient time has elapsed for these changes to have come to pass, though the wisdom of leaving the patient exposed to the dangers inseparable from the presence of an ectopic gestation sac in the abdomen for an indefinite period on a hypothetical assumption, is certainly open to criticism.

There is, however, reason to suppose that in cases in which the fœtus perishes at an earlier period in the history of an ectopic gestation, this prompt devascularisation and degeneration of the placenta may not take place, and that, instead, it may undergo further development. This possibility is evidently of the greatest practical importance, because if it can be proved to occur even occasionally it must modify current views as to the propriety of certain procedures.



2.—Section of ectopic placenta showing the chorionic villi. (Bland Sutton).

In a certain proportion of cases of extra-uterine fœtation in which abdominal section has been performed large masses of tissue have been removed, evidently composed of placental structure more or less altered in character. Sometimes the size of the placental mass is merely out of all proportion to the size of the fœtus. In other cases no trace whatever of the fœtus can be detected. Years ago, when the pathology of these abnormal gestations was enshrouded in mystery, the absence of the fœtus and the more or less unusual appearance of the placental tissue caused doubt to be thrown upon the accuracy of the diagnosis, and even at the present time there are surgeons who decline to accept anatomical proofs of ectopic gestation which do not comprise some indication of the present or past existence of a fœtus. It is, however, generally admitted at present that the discovery of a mass of tissue presenting microscopic evidence of chorionic villi is sufficient proof of the case being one of ectopic gestation.

The disappearance of the fœtus, indeed, has nothing in itself calculated to excite surprise or doubt. The existence of this frail mass of scarcely differentiated protoplasm is menaced from the very commencement. The abnormal situation and relations of the fœtal sac expose it to a large number of accidents any one of which may interfere with the blood supply and determine its death. During the first few weeks of fœtal life, the anatomical elements of which it is built up are peculiarly fragile, and in the event of an arrest of development they undergo degeneration and absorption with corresponding ease and rapidity leaving only the placenta, the vitality of which is not necessarily impaired, and which may even arrogate to itself the developmental energy left free by the death of the fœtus.

Let us consider for a moment what we sometimes observe under somewhat similar circumstances inside the uterus. In intra- as in extra-uterine gestation, the death of the fœtus is soon followed by more or less complete detachment of the placenta, along with the fœtus and membranes. When, however, the fœtus dies from some fault inherent to itself, abortive or vicious development or mere asthenic weakness, the vitality of the placenta, still in full vascular and physical connection with the uterine decidua, is not necessarily impaired. In a certain proportion of these cases therefore, the death of the fœtus does not bring about such a disturbance of the process of gestation as to call into play the vaso-motor changes preliminary to retrogression of the placenta, nor to set in movement the reflex expulsive mechanism of the uterine muscle. Under these circumstances a young and actively growing placenta may conceivably continue to thrive. In virtue of conditions as to the precise nature of which we are still in the dark, its further development may bear principally upon the connective tissue resulting in the formation of a carneous mole, a dense fleshy mass not unlike liver substance, and frequently quite free from any trace of fœtal remains, or the developmental energy liberated by the death of the fœtus may expend itself upon the fœtal part of the placental structures, that is to say, the villi, which become enormously hypertrophied, forming the peculiar product of conception known as the hydatidiform mole. The fact that the fœtal part of the intra-uterine placenta can thus indulge in proliferative vagaries after the death of the fœtus is a point upon which I wish to lay stress in view of subsequent events.

In neither of these varieties of mole is any trace of the fœtus usually found, yet they are undeniably irregular products of conception. Sooner or later, however, either because the abnormal intra-uterine placental growth has reached the term of its development, or because its irregular and rapid increase in size excites the uterus to contraction, the mass is expelled and the matter is at an end. Moreover, the form of intra-uterine polypus known as placental polypus, is believed to result from a proliferative growth of an adherent fragment of placenta. Adhesion implies close vascular connection to the uterine substance, and this evidently enables the torn off fragment of placenta to resist degeneration and to take on a low form of growth, or at any rate to increase in size. The prime factor then would seem to be the maintenance of a sufficient vascular connection, and given this, the placenta, or even a piece of the placenta is apparently enabled to continue to develop.

Now, there is no reason why, a placenta which, instead of occupying its usual position in the uterus has contracted adhesions to some intra-abdominal structure, and has secured an adequate and possibly luxuriant blood supply, should not recapitulate outside the uterus what I have shown not unfrequently to take place within that organ. The delicate nervo-muscular apparatus of the pregnant uterus which, under ordinary circumstances, usually brings the whole process to an end when the fœtus has succumbed, is lacking when the fœtal sac is outside and independent of the uterus. Hence the vascular changes and the muscular contractions which lead to the detachment of the placenta, and its expulsion *à la suite* of the blighted ovum, do not and cannot effect similar changes when the gestation is ectopic. *Ceteris paribus* then, the placenta would seem to be much more likely to retain its developmental activity outside than inside the uterus.

The death of the fœtus in ectopic gestation and the retrogression and absorption of the placenta is at first sight the easiest way out of a position of exceeding danger for the unhappy victim of this abnormality. Acting on this assumption, various methods of treatment have been devised, having for object to bring about the death of the fœtus, in the hope that the fœtus having succumbed, all further risk would be obviated. Thus we hear of aspiration of the fœtal sac (never a very successful procedure), the injection of toxic substances into the sac and more recently, the passage of a current of electricity through the sac, of successful instances of which our American *confrères* have been exceedingly lavish. Indeed, all these methods, if one may believe their adepts, have given excellent results, but, unfortunately for their statistics, the diagnosis in the successful cases has always been, and must necessarily be, a matter of doubt. If the diagnosis has been confirmed in some unsuccessful cases, the fact may fairly be used as an argument in favour of the view that the lack of success was a logical sequence of a correct diagnosis, in other words that in genuine cases of ectopic gestation the treatment was either useless or absolutely mischievous. I may further observe in this relationship that the diagnosis in the early stages of extra-uterine pregnancy is always more or less a matter of conjecture. Indeed, Mr. Lawson Tait seems disposed to deny its possibility, except as a matter of guess-work. In any event, although his experience of such cases has been enormous, he only once had opportunity of making the diagnosis in the pre-rupture stage, and that one he overlooked. Moreover, there is in reality very little opportunity for studying the clinical signs of the early stages for the simple reason that, as a general rule, there is nothing in the symptoms calculated to induce the woman to seek skilled advice. It is usually not until copious and terrible hæmorrhage suddenly occurs that a suspicion of something wrong is entertained.

Theoretically, if by any of the foregoing means the death of the fœtus could be brought about, the most pressing danger to the fœtus will have been averted, but there remains the danger, among many others, that the further development of the placenta may expose the woman to all the risks inseparable from rupture of the sac and dangerous, possibly fatal hæmorrhage. The fact of the death of the fœtus having taken place independently of any concomitant impairment of placental vitality renders possible, if not probable, what I am prepared to admit is certainly a rare condition.

Some of the unsuccessful cases of extra-uterine gestation that have been treated in America by the use of the electrical current have subsequently been operated upon and the fœtal sac removed by laparotomy. In some (though in what proportion I have for obvious reasons been unable to ascertain) the characteristic large placental mass has been found and removed showing either no fœtus at all or one disproportionately small. It is quite possible that in these cases the electrical treatment effected what nature does in others, viz. the death of the fœtus, leaving the placenta to grow until pressure symptoms led to an operation for its removal.

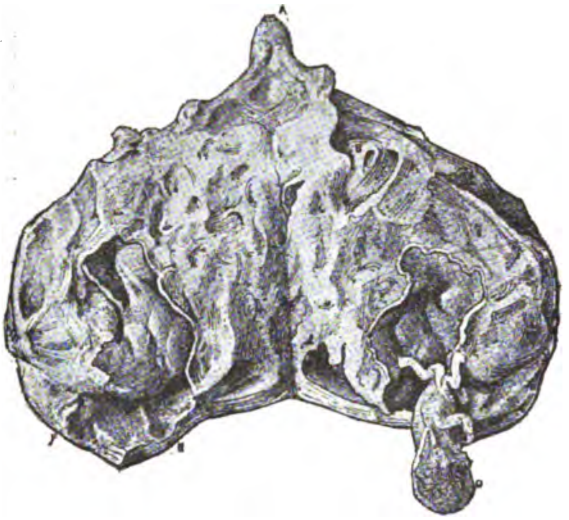
There is no lack of cases diagnosed previously to operation to belong to this category in which only placental tissue was found or in which the disproportionate size of the fœtus and the placenta respectively, justify the assumption of the subsequent growth of the latter.

Dr. Recamier of Paris, has kindly placed at my disposal the following notes of a case successfully operated on by him. A. D—, æt. 40, admitted to the hôpital St. Michel complaining of copious hæmorrhage and uterine pain. Menstruation had always been regular but abundant and painful. She had had two miscarriages after her first marriage and two children of a second. On Sept. 8th, she was suddenly attacked with severe pain in the abdomen, her menstrual period being at that time eight weeks overdue. The pain lasted all night and was followed in the morning by an escape of blood per vaginam which gave immediate relief. Since that time she had suffered from recurrent floodings and pain in the right side increased by walking. By abdominal palpation he made out a rounded mass in the right iliac fossa adherent to the parietes. The tumour was felt per vaginam to be joined to the uterus only by a thickened cord comprised in the right broad ligament. He diagnosed hemato-salpinx or ectopic pregnancy. On Nov. 10th he opened the abdomen by means of an abdominal incision and having cut into the peritoneal cavity he came upon a tumour the size of a child's head, extensively adherent to adjacent structures. Having removed it he identified the right Fallopian tube, much dilated, and tied it level with the uterus. The tumour consisted of the dilated tube with thickened walls filled with dark blood clots and containing a cystic cavity likewise filled with clots. On the upper and posterior part of the sac was a three or four months' placenta but no traces of a fœtus nor of fœtal structures could be found even after the most careful examination.

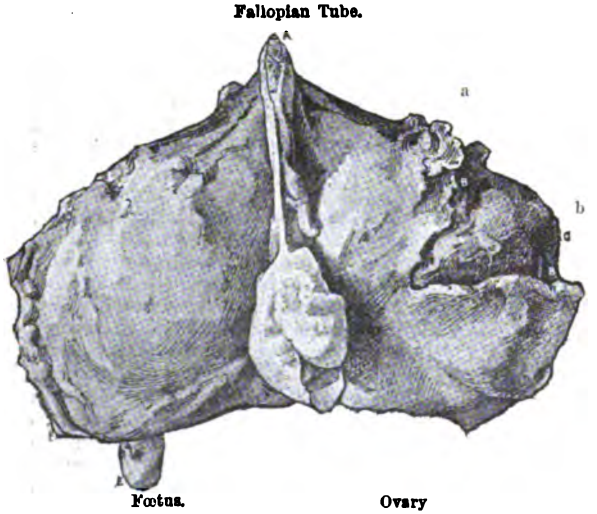
Dr. John Williams ("Obstet. Trans." vol. 29) relates a case of ectopic pregnancy in which abdominal section was performed during the life of the fœtus at the 35th week of gestation. In this case the child was removed and the placenta left *in situ*. For two weeks after the operation it maintained its fluctuating character and then became solid. A month after the operation portions of it contained blood which was still fluid.

A very interesting case is recorded in Dechambre's *Dictionnaire Encyclopédique des Sciences Médicales*, under the heading of "Grossesse," which seems to support the hypothesis of the persistent growth of the placenta after the death of the fœtus. It shows, moreover how serious are the dangers to which the patient is thereby exposed. The case was that of a woman who was admitted to the service of Prof. Pinard at the Lariboisière Hospital, and succumbed in his wards to an attack of peritonitis caused by the rupture of an ectopic gestation. Post-mortem, in the right iliac fossa, behind the uterus and to the right of the fœtal cyst on which it appeared to be grafted, was seen a mass the size of two fists, nodulated, of a dark colour, and apparently of spongy consistence, surrounded by clots. On a level with the lower part of the mass, just at the spot where it rested on the floor of the iliac fossa the clots were more abundant than elsewhere. This was evidently the starting-point of the hæmorrhage, indeed, on carefully removing the clots, it was seen that the mass contained a cavity the size of a walnut. It turned out to be a placental hæmorrhage, the mass in question being the placenta, markedly hypertrophied. The placental mass, perfectly distinct from the fœtal cyst, was surrounded by a slightly adherent membrane which seem to be part of the cyst wall, from which, however, it could be easily detached. It was then seen that the wall of the cyst, at a point corresponding with the insertion of the placenta, presented an irregular laceration with clearly defined edges, through which passed the umbilical cord, still connected with the placenta. The latter weighed 425 grammes (one English pound). On section, hæmorrhagic foci could be seen disseminated here and there. One of them more superficial than the others opened into the peritoneal cavity, and was obviously the source of the final hæmorrhage. The fœtus weighed 625 grammes, and measured 30 cm. long. Although in this case one does not meet with the disproportion between the size of the fœtus and the placenta to which I have called attention elsewhere, it is evident that the placenta had preserved its vitality subsequently to the death of the fœtus, and that its continued growth had in all probability determined the rupture of the sac, the cause of the fatal hæmorrhage. The death of the fœtus must have taken place some time previously, yet we find that the placenta showed no indications of undergoing the changes in the direction of devascularisation which usually follow that event.

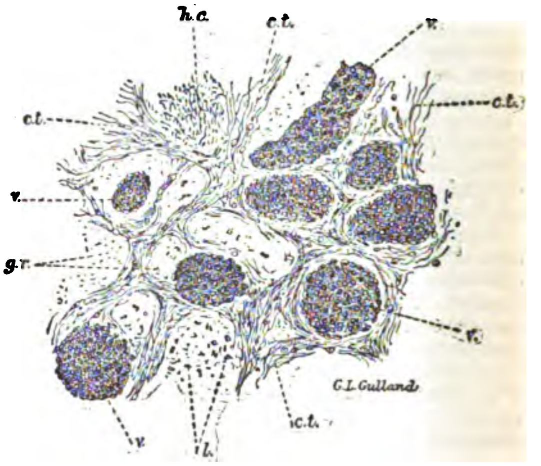
Quite recently MM. Lawson Tait and Christopher Martin communicated to the Royal Medical and Surgical Society the notes of a case which have an important bearing on this much disputed point. The patient was a married woman, æt. 38, with one child, born two years before. The patient declared that menstruation had always been perfectly regular. Two months previously to her admission to the hospital she was seized with violent pains in the lower abdomen, followed by syncope. The temperature soon after rose rapidly, and the abdomen became very tender. Fifteen days later the attack was repeated, the pain being most acute in the left iliac fossa. On vaginal examination the ute[illegible] was found to be heavier and less mobile than [illegible], but no other indication of pregnancy could be detected. Laparotomy was performed, and the peritoneal cavity was found filled with clots, some of old standing, others of more recent formation. The uterine appendages on the right side were adherent but healthy, but the left Fallopian tube contained a gestation sac the size of an orange. The amniotic membrane was torn, and through the rent the fœtus, which measured about an inch in length, had passed into the peritoneal cavity. The swelling in the Fallopian tube was formed chiefly of placental tissue infiltrated with blood. The placental chorionic villi had contracted adhesions to the tissues of the Fallopian tube. The authors were of opinion that the case was one of rupture at about the second month of pregnancy of an ectopic gestation, and that in all probability the placenta had continued to grow after the death of the fœtus. In any event, it had attained the size of a seven months' placenta, while the size of the fœtus apparently did not exceed that of a fœtus at seven or eight weeks.



3.—Tubal pregnancy cyst split open to show amniotic cavity and placenta. (a) Fallopian tube; (c) fœtus; (f) fœtal surface of the placenta; (g) muscular coat of Fallopian tube. (Tait and Martin).



Posterior aspect of same showing rent in Fallopian tube (a.) The protruding placenta is seen at(b). (Tait and Martin).



4.—Extra-uterine placenta at 4½ months. X, 200; v, chorionic villi; h.c., crystals of hæmatoidin; g.r., granular *débris*. (Berry Hart.)

It may not be without interest to recall that Morgagni ("De Sectibus et Causis Morborum") was of opinion that, "In cases where the placenta is larger than the fœtus the organ has probably continued to grow after the death of the latter. In many cases the small size of the fœtus may explain how it is that it often escapes observation."

In a case reported by Dr. Herman ("Obstet. Trans.," vol. 28) the fœtus weighed three and a half pounds, and the placenta 28½ ounces.

Dr. Bantock (*B. Gyn. Jour.*, 1891) mentions having operated upon a lady for ectopic gestation in the right Fallopian tube, which formed with the placenta a tumour nearly as large as the adult head. The fœtus had been extruded, and was found in the left iliac fossa free from any connection with its placenta. The latter, however, was as large as at term, yet it was evident that the fœtus had died at three or four months, so that he found himself constrained to admit that the placenta must have gone on growing.

Dr. Mendes de Leon (Amsterdam) in a case of ectopic gestation, contributed by him to the *Brit. Gyn. Jour.*, for November, 1891, mentions a somewhat similar condition of things. He does not, however, appear disposed to admit that the placenta in these cases is at all likely, as suggested by Mr. Tait, to take on further development after the death of the fœtus, and to give rise later on to fatal hæmorrhage. Probably, he says, it is not a question of the development of real placental tissue, but rather of the anomaly known as placental polypus, a degenerative form of placental growth frequently observed after incomplete abortion. I must confess I do not follow him in this assumption, for he does not explain how he distinguishes between the placenta proper, and the outgrowth to which he accords the name of polypus, a designation which is etymologically and pathologically incorrect when applied to any portion of an extra-uterine placenta.

(*To be continued.*)

FORCED RESPIRATION.

By GEORGE FOY, F.R.C.S.,
Surgeon to the Whitworth Hospital; and formerly Lecturer on Anatomy and Forensic Medicine in the Carmichael School of Medicine.

During the past eight years I have from time to time drawn the attention of the medical profession to the value of oxygen gas passed in a full stream, from the bottle containing the compressed gas, into the lungs of patients suffering from asphyxia.

In "Anæsthetics: Ancient and Modern," I recommended it as a remedy for anæsthetic narcosis, and I demonstrated the value of the forcible pouring into the lung of oxygen in the asphyxia supervening in double pneumonia in the Whitworth Hospital, Drumcondra, on the 11th of June, 1891. The idea, has, however, been independently and more efficiently carried out in America by Dr. George E. Fell, of the City of Buffalo, N.Y., whose paper on "Forced Respiration," (the *Canada Medical Record*, January, 1894), read before the section of General Medicine at the Pan-American Medical Congress, September, 1893, advocates forcibly passing atmospheric air or oxygen gas into the lungs in cases of narcotic poisoning, drowning, and still-birth.

At first Dr. Fell used the apparatus which he used for forcible respiration in physiological experiments on dogs; he afterwards devised a more suitable one and which could be used by laymen for the resuscitation of persons apparently drownded.

Up to this Dr. Fell has published forty-four cases in all of which unmistakable evidence of the value of forced respiration is given.

His first case, which occurred in July, 1887, is that of a man who took "chloral to produce sleep, but finding this unsuccessful, he added twenty grains of morphina." Ten hours elapsed before forced respirations were commenced, and after they "had been under way two and one-half hours, the ordinary tracheotomy tube was substituted for the tube of the apparatus, and the patient allowed to breathe for himself."

The second case occurred under the care of Dr. Boehm, of Vienna, the patient, an adult, took eight grains and a half of morphia dissolved in water. Artificial respiration was tried for four hours and a half. "As it was now apparent that artificial respiration was not sufficient to restore normal breathing, tracheotomy was performed. A canula connected with a bellows was introduced and forced respiration kept up for three or four hours. At 5 p.m. the use of the bellows could be dispensed with, and our attention entirely devoted to watching the natural respiration."

Case III, under Dr. Fell's care, was narcosis from two ounces of laudanum and an unknown amount of chloral. Forced respiration commenced six hours after the opium was taken. "After nearly fifteen hours of forced respiration the patient began breathing for himself."

His most remarkable case is No. IV. A man, æt. 45, who took two ounces of laudanum and cut his throat, "severing the trachea and the anterior jugular vein." The patient was hours in this condition before he was discovered. "Some twelve hours after we had been at work, the satisfactory result of forced respiration, as a means of breathing for a human being, was demonstrated in the passive condition of the patient. During the forenoon the effect of the narcotic gradually passed away."

The case in which Dr. Fell used oxygen gas was that of a man who took "a large poisonous dose" of a mixture of phenacetine, morphine, and cocaine. "In this case oxygen gas was administered in connection with the forced resqiration apparatus. . . . . . . The results were satisfactory but the odds against which we were fighting—the combination of deadly drugs which had been taken—were too much for even an expectation that success would crown our efforts."

In the great majority of the cases enumerated in the paper, Sylvester's method of artificial respiration and the usual antidotal remedies had been unsuccessfully tried, and in almost every instance the patient appeared to be at the point of death when Dr. Fell was called on to try his method of forced respiration. The good results obtained are the best evidences of its great value, and there is little doubt but that forced respiration of atmospheric air, or oxygen gas will become more and more used.

As an antidote to opium, chloroform, ether, chloral, and narcotics generally I believe it is unequalled.

A PLEA FOR SYMPHYSIOTOMY. (*a*)

By Dr. ROBERT P. HARRIS,
Philadelphia.

Symphysiotomy is an operation with a somewhat early history. Too many of the women died, too many that did not die were disabled, and far too many children were lost. The first historical period of the operation extends from 1777 to 1858, and during this period some 150 symphysiotomies were performed. We have the full results in 114, under which 74 women and 41 children were saved. This gives a mortality of about 35 per cent. for the women, and nearly 64 per cent. for the children. These figures are a sufficient explanation why the operation was abandoned. Under Professors Morisani and Novi, in 1866, the mortality was reduced to 20 per cent. of the women (10 out of the first fifty) and 18 per cent. of the children. These two operators began a new era in 1886, and by a more rigid adherence to the sub-osseous method of section, aided by strict antiseptic precautions, they, with their followers, have shown that 50 women could be operated upon so as to save 48 of them and 44 children, a mortality of 4 and 12 per cent. respectively. Of the six children lost, one was immature. Both the women that died had been a very long time in labour, one of them 96 hours. With such a measure of success it is folly to decry the operation, or to assert that it is not founded upon a rational basis. The operation is now under test in twelve countries, and will probably be performed as many as 200 times during the current year (1893); but several years must elapse before we shall be in a position to judge of its dangers and of its real mortality. With many trying it for the first time never having witnessed its performance, we shall be encouraged by the fact that only 9 cases proved fatal, out of the 83 operated on in 1892. In the United States there has been but one lost out of the last 15, although delivered under 12 different operators, ten of whom operated for the first time. Professor Pinard in Paris did not have a death until the twentieth case.

Outside Italy better progress has been made in saving the lives of the mothers, than in respect of the children. Two lives are at stake in the operation, and if both are not saved, there should be good and valid

---

(*a*) Read before the Obstetrical Society, March 7th, 1894.

reasons for the failure. Italy has reduced the fœtal mortality to 12 per cent., and a mortality not exceeding this should be aimed at in other countries. Of the 83 children born in 1892, 10 were stillborn, 2 were destroyed by the cranioclast, and ten died within three days of delivery, leaving 61 recorded as "saved," or 73·3 per cent. To save the fœtus the woman should be operated upon in good season, the size of the pelvis should be carefully ascertained, the child should be very carefully, and not hurriedly, delivered by the forceps applied to the sides of the head, and if asphyxiated appropriate measures should be taken for its restoration.

The first symphysiotomy in the United States was the third of its kind, the first and second having been performed by Professor Pinard. It was done by Dr. W. T. Coggin, March 12th, 1892. The patient was the wife of a miner, a primipara, aged 23, 5 feet 7 inches high, with a contracted pelvis and a very large fœtus. Dr. Coggin opened the symphysis, and delivered by the aid of the forceps a fœtus weighing 11¾ lbs. The sacro-iliac synchondroses were uninjured, as also the soft parts, and the woman made an excellent recovery. Both she and the child are now alive and well, the latter being close on two years old. This was the first of 31 operations in the United States. Of the children thus delivered, 21 were males and the average weight was 7¾ lbs. Of the women, 18 of the 31 were primiparæ.

The time in labour may be given as follows: Labours induced 2; for 6 hours or under 2; from 7 to 12 hours 5; from 13 to 18 hours 4; from 19 to 24 hours 7; from 25 to 36 hours 1; from 37 to 48 hours 5; from 49 to 60 hours 2; from 61 to 72 hours 2; and 4 days, 1. It will be seen that 22 of the 31 women were allowed to be in labour more than half a day and one half of these more than one whole day. Morisani gives 67 millimetres as the minimum conjugate measurement, but we give it at 70 millimetres, because of a greater average weight of the fetus. There have been 4 deaths among the cases in the States, numbers 10, 14, 16, and 26. No. 10 was in labour 25 hours, and was taken to the hospital with a pulse of 150; she died in 12 hours. No. 14, in labour 16 hours, died of septic peritonitis in 12 days; believed to have been infected prior to the operation; No. 16, in labour 20 hours, taken to Maternity in an emergency on a cold rainy day, had been drinking whisky, and died of pneumonia attributed to exposure. No. 26 had been in labour three days before going to Maternity. She died on the 11th day from sepsis, originating in the sub-osseous wound.

The occurrence of 9 fœtal deaths cannot be wondered at. No. 1 was in labour 22 hours, death in 24 hours; No. 5, labour 24 hours, death on third day from meningeal hæmorrhage; No. 10, labour 25 hours, death in 17 hours from injuries prior to admission to hospital; No. 14, labour 16 hours, stillborn; No. 17, labour 50 hours, stillborn; No. 20, labour 28 hours, stillborn; No. 22, labour 21 hours, death soon after delivery; No. 29, labour induced conjugata vera 67 mm., death from injuries in delivery by the feet; No. 31, labour 4 days, stillborn. Early operations should have saved nearly all these children with the exception, of course, of Case 29.

◆

Selected Prescriptions and Therapeutic Notes.

89.—For Congestive and Inflammatory Conditions of the Ears the following will be found useful:—

℞ Resorcin, gr. iss;
Cocainæ hyrdochlor, ʒvij;
Morphini hydrochlor, gr. 1-6th;
Aq. destill, ʒiiss.

M. For external use by instillation.—Dr. Stein.

90.—Epistaxis of the Nasal Septum.—Dr. V. Cozzolino speaks of a new hæmostatic antiseptic medication in epistaxis of the nasal septum, and surgical hæmorrhage of the same, of the turbinated bones, aural cavities, etc., in the *Rivista Clinica e Terapeutica*, Oct. 1893. The remedy which the author recommends and praises, and to which he attributes the above-mentioned properties, is trichloracetic acid, with which he, by accident, was led to experiment. He prefers a solution of one part of acid in thirty or forty of sterilised water, with the addition of a small quantity of cocaine. A small pledget of cotton is moistened with the solution (which may be weaker—one in eighty or one hundred), and applied *in situ*. He extends the application also to other hæmorrhages of different origin, and adds an application of direct compression of the septum, made by means of Jurasz's forceps for deviation of the nasal septum, and placing between this and the blades iodoform or sublimate gauze.—*Pacific Medical Journal.*

91.—A Good Antiseptic for the Urinary Tract:—

Potassium Permanganate solution (1 to 1,000) is an excellent local antiseptic for the urinary tract. One of the advantages it has over other agents is that so long as pus or other excrementitious matter is present the fluid will be changed in colour from the deoxidation. For acute gonorrhœa it is particularly applicable, and in the preparation of cases for operation.

92.—An Antiseptic Varnish.—Dr. Berlioz, of Grenoble, gives the formula for an antiseptic varnish which he calls sterisol:—

℞ Gum lac (purified, very
soluble in alcohol, ℥ix;
Powdered benzoin, ʒijss;
Tolu balsam, ʒijss;
Crystallised phenic acid, ℥iij;
Essence of cinnamon,
Saccharine, āā, ʒjss;
Alcohol, ad. Oij.

The employment of this varnish is indicated wherever there is an abrasion of the mucous membrane, as in diphtheria, mucous patches, herpes, &c. It adheres to the mucous membranes as well as to the skin, over which it forms a thin pellicle.—*N.Y. Medical Record.*

93.—For Sea-sickness:—

℞ Antipyrin, gr. lxxv;
Cocainæ hydrochlor, gr. iss;
Caffeini, gr. iv;
Strychninæ sulph, gr. 1-30th;
Sp. vin. gallici, ʒijss;
Aq. destill, ad. ℥iij.

M. A tablespoonful before embarking, and others during the day, or three during the twenty-four hours.—Rouqette.

◆

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, March 7th, 1894.

The President, Dr. G. E. Herman, in the Chair.

Dr. R. P. Harris (Philadelphia) read a paper on "A Plea for Symphysiotomy," which will be found under Original Communications.

In the discussion which ensued,

Dr. Lewers could not explain why the operation had failed to become popular in England, a good claim having been made out for symphysiotomy in suitable cases. He explained the very different conclusions arrived at in respect of the possible gain of available space by the operation, pointing out that division of the symphysis did increase the available space to the extent described, if performed on the bodies of women who had died in labour, but that if performed two or three weeks after labour, the increase of the available space was not nearly so great. Both sets of observations were therefore correct, so far as they went, but in discussing symphysiotomy it was necessary to bear in mind that they were operating upon women in labour. The heavy mortality in the first period, alluded to by the author, was probably largely due to a want of antiseptic precautions, and the adoption of the operation in many instances of extreme contraction of the pelvis for which it was altogether unsuitable. Moreover, the last ten cases of this first period showed a mortality of 50 per cent., mother and fœtus, so that it was not a mortality which decreased with experience. The special indication for the operation was failure to effect delivery by other means *at an advanced stage of labour*, that is to say, at a time when turning would not be available.

Dr. **Horrocks** pointed out that not only mortality of the operation, but the possible and ultimate effects to the woman had to be taken into account. Personally he would prefer Cæsarian section, or turning, to symphysiotomy.

Dr. **Griffith** said the reason why symphysiotomy was still an unpopular operation in this country was because it deserved to be unpopular, judged on its own merits, and because it was not the best operation under the circumstances. He commented on the fact that in Paris they were actually giving up the forceps, premature induction of labour, and turning, and were, in fact, going to such extremes that their conduct, was, in itself, enough to damage the reputation of such an operation. He himself had had under his care 3,000 cases of labour, and since symphysiotomy was reintroduced he had not met with a single case in which he considered it would have been justifiable. To justify recourse to this operation there must be a living fœtus and a moderate degree of pelvic contraction (not absolute, but compared to the size of the fœtal head). In most cases premature labour would be induced with every prospect of saving both mother and child. When the child was dead then of course symphysiotomy was out of the question. Although there was undoubtedly a certain group of cases in which symphysiotomy might properly be resorted to. He said that if he were a woman he would sooner run the risk of Cæsarian section, skilfully performed, than try symphysiotomy.

Dr. **Leith Napier** raised the question as to how far symphysiotomy could be relied upon to obtain an increased diameter of the pelvis. The minimum conjugate diameter for the operation had been given at 2¾ inches, but in such a case, he urged that it would be better to try turning. It had been shown that cases which were not amenable to forceps may often be delivered by turning. Possibly the French prefer symphysiotomy because they lack the "sixteen stone behind the forceps," which had been said to be necessary as a *vis a fronte*. He asserted that it was impossible to find practitioners all over the country who could be expected to perform symphysiotomy with credit to themselves or safety to their patients. The measurement of 2¾ inches, moreover, was the diameter given by Leopold, of Dresden, as that for Cæsarian section. If really they could obtain 2¾ inches extra diameter by symphysiotomy, they had been making a dreadful mistake in the mechanics of labour, for it had all along been taught that 1 inch was the most that could thus be gained. Personally, I do not believe that this amount of additional diameter could be obtained. They had 4,000 deliveries a year, without having come across a single case during the last two years in which, in their opinion, symphysiotomy would have been justifiable.

Dr. **Herman** observed that the thanks of obstetricians were due to the gentlemen who have been bold enough to try the new method, for new it practically was, but he himself was convinced that symphysiotomy had not yet justified its claim to take its place as a method which ought to be received as one of the ordinary means of effecting delivery in difficult cases. The author had shown a mortality of 10 per cent. and Pinard's mortality was about the same. With Cæsarian section in selected cases, the operation being performed at a selected time, in hospital, and by experienced surgeons with proper assistance, the mortality was not greater than 10 per cent. Therefore, in point of mortality, symphysiotomy had no advantage. As to sterilising the patient, this could be done by removing the ovaries, but it remains to be seen whether this could be surely accomplished by tying the tubes. He asked what was the condition of the patients operated upon by symphysiotomy in respect of laborious work. Dr. Lewer's patient could walk, but she had stated that she was unable to scrub, and the other records were silent on that point. He asked also whether the operation could be safely repeated in the event of subsequent pregnancies? In a case reported by Dr. Smyly, of Dublin, the urethra was lacerated, and he asked whether this was a frequent accident. On the whole, he thought Cæsarian section offered the best prospect of success and of survival where the patient wished a living child, which could not be born without some operation of the kind.

ON THE RELATION OF HEART DISEASE TO MENSTRUATION.

Dr. W. J. Gow—Particulars with regard to menstruation were given of fifty cases. In twenty-eight the menstrual flow was unaltered. In seventeen the flow was absent or scantier than before. In five the flow was either more profuse or recurred more frequently than before. In no case was there good evidence that heart disease gave rise to severe menorrhagia. It would seem that either amenorrhœa or scanty menstruation was a far more common accompaniment of heart disease than menorrhagia. A further analysis of these cases seemed to point to the fact that heart disease led to relative sterility, and also that it greatly increased the tendency to premature expulsion of the ovum. In conclusion, it was pointed out that a large number of women, suffering from valvular disease of the heart, pass safely through the period of pregnancy and labour.

Dr. **John Phillips** said he had given this subject a good deal of attention before he was aware that the author was engaged on the same study. His method of examination was to examine the heart in all women who were menstruating, in all some 656 cases. Only 17 proved to have valvular disease of the heart, and of these 11 came because they were pregnant. He had followed 9 of these through their confinement to ascertain the effect of the heart disease in menstruation. Six were not pregnant; and of these 4 had mitral and 2 aortic disease. The tendency in all was towards amenorrhœa, and not towards menorrhagia. As a matter of fact, he had never seen a case of menorrhagia in connection with heart disease. He was of opinion that women with heart disease were just as likely to become pregnant as others, though there was probably a greater tendency to abort.

Dr. **Horrocks** said he had approached the subject from another point of view, viz., by looking over the post-mortem records of cases of heart disease, and then referring to the clinical records to observe what had been noted in respect of menstruation. Unfortunately, these records were often silent as to menstruation, and this was a point to which he desired to call attention. The author's statistics were founded on cases observed during life, so that he could have had no information with respect to the condition of these viscera. There might have been present some condition of the other viscera, or of the uterus, which might account for either the menorrhagia or the amenorrhœa independently of the heart disease. His observations tended to confirm his and Dr. Phillips' conclusion that heart disease does not cause any increase of the flow. He pointed out as a noteworthy fact that in very few of the author's cases was there œdema or other indication of circulatory breakdown. He accused the text-books of promulgating the assertion that heart disease tended to the production of menorrhagia, the assumption being based on the fact that valvular disease tended to produce congestion of the viscera.

Dr. G. **Herman** recalled that a paper on this subject was brought before the Royal Medical and Chirurgical Society not long since, in which the author based his conclusions on the auscultation of patients applying in the obstetrical out-patient room. He pointed out that such a method was evidently faulty, because the women in many cases would be applying in consequence of their being something wrong with the uterus. The author's conclusions appeared to him to be unassailable. He himself had made some observations on the effect of heart disease along with disease of the liver and lungs on menstruation, and he had found that they tended more to the production of amenorrhœa than menorrhagia. The late Matthews Duncan, in his "Clinical Lectures," long since stated that his experience did not bear out the alleged association of heart disease with menorrhagia.

Dr. **Griffith** referred to the case of a young servant girl who came to the Samaritan Hospital complaining of severe menorrhagia. After giving various remedies which failed to procure relief, he proposed a vaginal examination, but he discovered that she had valvular disease of the heart, whereupon he relinquished the use of ergot, &c. She subsequently married and had a child. The menstrual period in her case lasted ten or twelve days, and the menorrhagia only dated from two or three years, so that it not improbably had some connection with the cardiac lesion.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, March 2nd.

The President, **Dr. Walter G. Smith**, in the Chair.

THE SEQUEL OF A CASE OF MYXŒDEMA TREATED BY THYROID JUICE.

Dr. Little gave an account of the subsequent progress of a case of myxœdema which had been treated successfully by the hypodermic injection of thyroid juice, and the notes of which he had communicated to the Academy in April last.

Dr. A. **Paton** mentioned the case of an old lady who suffered from enlarged face, hands, and feet, and whom he treated with 10-minim doses of the extract of the thyroid gland three times a day. The swelling diminished very much, as well as a hæmatoma present in the left ear. Her expression is still heavy and drowsy, but there is no return of the swelling in the hands and feet.

Dr. **Hawtrey Benson** said that last April he had narrated the history of a case of myxœdema cured by the internal administration of thyroid juice. He was happy to state that his patient was in perfect health still. She had taken small doses of the extract continuously since he had seen her. He thought that it was well always to begin the treatment of these cases by the internal administration of the juice, and if, after a fair trial, this method did not prove efficacious, to resort to the hypodermic method. It was not always possible to obtain the juice in a sufficiently aseptic condition for hypodermic injection.

The **President** remarked that it was interesting that it did not seem to matter much whether the juice were given by the mouth or under the skin. If it owed its activity to some body belonging to the class of nucleo-albumen, it would naturally be imagined that gastric digestion would have some influence on its action.

Dr. **Little**, in reply, stated that some evidence existed as to harm being sometimes done by these extracts. A doctor in the Queen's County informed him that he had cured a patient of a large bronchocele by means of the extract, but that his patient had become greatly emaciated. He had himself noticed some rather alarming symptoms in two ladies, patients of his own. One of them, a hysterical girl, became very nervous and hysterical, and necessitated some nurses being engaged to watch her. In the other case the lady, after a few days, developed violent headache and pain in her abdomen, and similar symptoms came on after a fresh trial.

ON THE TREATMENT OF BRIGHT'S DISEASE.

Dr. **Michael F. Cox** submitted a report of two cases of acute Bright's disease which he had successfully treated, commenting at the same time on the generally unsatisfactory results obtained in the treatment of Bright's disease. The first case had occurred nearly eighteen years ago. It was that of a gentleman, æt. 47, who, from exposure to wetting and excessive indulgence in alcohol, suddenly developed symptoms of Bright's disease, complicated with uræmic convulsions, maniacal excitement, coma, amaurosis, and who, chiefly by free purgation and copious leeching, ultimately recovered perfectly, and still remains well. The other recently occurred, and was attended by oligura and a great amount of albuminuria and extensive anasarca. Improvement being tardy under ordinary diaphoretic and other such treatment, the patient was put on 15 gr. doses of diuretin three times a day, with the result that the urine which was reduced [illegible] one pint a day was doubled every succeeding day until it nearly reached sixteen pints in five days, maintaining its specific gravity, whilst the albumen and dropsy entirely disappeared, and the patient was soon enabled to leave quite well.

The **President** asked had the urine of Dr. Cox's first patient been frequently tested since his illness. It was not an uncommon experience for patients to recover from uræmic convulsions and to live and pursue an active life for many years. With regard to diuretin he had not been favourably impressed. It was an unstable and costly compound, and there was not much clinical evidence to show that it acted well. In treating acute nephritis our great aim should be to do nothing to injure the patient. Chronic nephritis he believed to be scarcely ever, if ever, cured.

Dr. **James Little** said that he had tried diuretin in a case of ascites from contracted liver, and had not found it of use. With regard to the hot-air bath in the treatment of cases of nephritis, he said that he had watched several very intelligent patients, and inquired from them whether they were relieved by it, and they said they were not, but were less comfortable. Theoretically it would seem that the removal of a large quantity of water through the skin would make it more difficult to wash out the tubules of the kidney. In only two cases had he seen a hot-air bath do good, and in these the patient's life was endangered from the accumulation of a large quantity of fluid in the pleural sacs. He had seen many patients much disimproved by being given iron too early. Where uræmic symptoms threatened, a free purging with calomel seemed to give relief.

Dr. Cox, in reply, said that his first case had been examined several times by a medical friend in the country, and that his urine had been tested. No albumen was found. He could not say whether any albumen was occasionally present, as he had not the opportunity of testing it; but the patient was alive, and to all appearance healthy. He had seen diuretin relieve a patient of his suffering from dysuria, and another patient of a scrofulous diathesis who had occasional attacks of dropsy. In some other cases he had not found it so successful. He had seen minim doses of croton oil and pilocarpine in from quarter to half grain doses relieve a patient who had suppression of urine and uræmia with maniacal symptoms following the introduction of instruments into the urethra and bladder.

The Section then adjourned.

◆

THE HUNTERIAN SOCIETY.

Meeting held Wednesday, March 14th.

The President, Mr. **F. C. Symonds**, F.R.C.S., in the Chair.

Cast of Hunter.—**Dr. Braxton Hicks** presented to the Society a framed cast of Tassie's medallion portrait of John Hunter. The original portrait was "done from life" by Tassie in 1791 in wax and then in "Tassie's paste," a readily fusible opaque glass. An engraving of it appears as the frontispiece to the new edition of the "Treatise on the Blood. Inflammation and Gunshot Wounds," 1828.

Multilocular Fibroid Tumour of the Uterus.—The **President** in showing this specimen said he had found enucleation an impossibility, and had removed uterus and appendages. He had used the clamp and the patient made a good recovery. He had had two similar cases, in one he had used the clamp and in the other had divided the cervix and had sutured the peritoneum over the stump. Both cases recovered.

Tubal Gestation.—Dr. **Galloway** showed a specimen of tubal gestation which had ruptured half an hour before death. He judged the age of the gestation was about two months. The patient died of hæmorrhage and shock.

The **President** narrated a case on which he had been asked to operate. The patient had had three attacks of sudden internal abdominal hæmorrhage. Exploration was undertaken with a successful result. He remarked upon the early stage of the gestation, and asked whether in the experience of any Fellow of the Society tubal gestation in the lateral parts of the tube was more likely to rupture than one close to the uterus.

Dr. **Percy Warner** mentioned a case where there had been four attacks of severe hæmorrhage, accompanied by a shock. The diagnosis was difficult; exploration was performed and the tube excised, the patient making a good recovery. A point of interest in these cases was whether the sexual appetite was lost after removal of the tubes. He had noticed that in one case the sexual appetite had been lost.

Dr. **Herman** said he considered that it was undoubted that the gestation went on longer when the sac was situated in the outer part of the Fallopian tube. He could not see what a sudden intra-abdominal hæmorrhage in a woman who presented signs of pregnancy could be except a ruptured gestation or a ruptured varicose vein of the broad ligament. The treatment of both was the same.

Dr. **Braxton Hicks** remarked that the diagnosis would be difficult because the tumour was so small in this case.

Dr. W. **Eccles** exhibited a case of "Monoculus Fœtus."

The Organisms of Malaria.—Dr. **Manson** exhibited under the microscope the blood of a malarious patient containing specimens of the organisms of malaria. He remarked that the organism existed in several forms, the relations of which to each other had not yet been decided. Two forms were well known, the intracorpuscular form, consisting of corpuscles with pale black pigment in the centre, exhibiting amœboid movement at the edge. When mature, the cell burst, and allowed the spores of the parasite to fall into the blood-stream. These were immediately attacked by leucocytes, or re-entered the red cells again to develop. Another form consists of a central spherical mass of black pigment, to the periphery of which cell there are flagellæ attached. A third form consists of egg-shaped oval red bodies.

Dr. **Manson** also exhibited microscopical specimens of sputum containing ova from a case of pulmonary distomiasis. He said the disease was common in China and Japan. The parasite lived in burrows in the lung substance and bronchial walls. The ova were deposited and coughed up in the sputum in myriads. The parasite gave rise to signs which simulated aneurysm, spasmodic cough, and sanguineous expectoration. Dr. Manson remarked that aneurysm was especially common in the East, as common as phthisis in London.

Secondary Carcinomata.—Dr. **Galloway** exhibited an uncommon form of secondary carcinoma from a patient who died of dyspnœa. Both elbow-joints were enlarged, and the lower ends of the humeri were involved in carcinomatous growths. In one arm there had been a spontaneous fracture of the humerus. Dr. Galloway thought the case important as showing how intimate was the relation between adenoma and carcinoma.

The **President** remarked he had seen secondary carcinoma of the lung associated with tumour of the thyroid.

Thoracic Aneurysm.—Dr. **Fyffe** exhibited a specimen of thoracic aneurysm with ulcerative endocarditis, patches of ulceration in the aortic valves, in which diplococci had been found. He remarked that until micro-organisms were found, ulcerative endocarditis ought not to be diagnosed.

Dr. **Hadley** asked how long the patient lived. In most cases he had seen, three or four months was the duration of life from the time the disease was diagnosed.

Dr. **Chaplin** mentioned a case which he had exhibited where a huge vegetation on the pulmonary valve had caused death. He thought the valve affected was an important item.

Dr. **Fyffe**, in reply, said he thought about six weeks was the duration of life. He had once seen the tricuspid valve affected in a case of congenital heart disease. In one case of ulcerative endocarditis, there was a residual abscess in the neck, from which, although opened with a sterilised knife, diplomucocci were cultivated. He thought, therefore, that residual abscesses were infective.

◆

LIVERPOOL MEDICAL SOCIETY.

Meeting held Thursday, March 15th.

The President, Mr. C. Puzey, in the chair.

MEDICAL ELECTRICITY.

Mr. **Bark** read a note on "apparatus by which the ordinary electric current, used in lighting houses, can be employed for medical purposes,"

Followed by a demonstration by Messrs. **Bark** and **Larkin**, Electrolysis, Re-action of Degeneration, Trans-illumination, &c.

THE VALUE OF ABDOMINAL OPERATIONS IN THE TREATMENT OF MALIGNANT DISEASE OF THE ALIMENTARY TRACT.

Mr. **Damer Harrison** opened a debate on "The Value of Abdominal Operations in the Treatment of Malignant Disease of the Alimentary Tract." He brought forward statistics, and discussed the operations of gastrostomy, gastro-enterostomy, colotomy, and pylorectomy.

Dr. **Alexander** said that a few days ago he turned up accidentally a passage in Ranking's Abstract (vol. v, p. 283) where the following words are applied in regard to the advisability of ovariotomy:—"It cannot be defended, as we must not only take into consideration the accidents resulting from it, but the important fact that dropsy of the ovary may exist for a series of years without the health being materially compromised, who, under these circumstances, would dare to place the patient in danger of rapid dissolution!" The statement is only amusing to us now because we have learned how to perform ovariotomy. About fifteen years ago Dr. Alexander performed his first hysterectomy for cancer of the uterus by Freund's method, and the patient died from the operation. That was the general result then, but now-a-days by improved experience of his own and by taking hints from others he has had a succession of ten recoveries and the operation is so safe that surgeons do not think it worth while to report their cases. Surgeons are now engaged in a determined contest with disease of the alimentary tract, and their initial operations will probably be as unfavourable for a time as in the above mentioned instances and in other diseases that could be named, but the issue will, no doubt, be successful, and adverse opinions expressed to-night may sound as ridiculous in the future as the opinion I have quoted about ovariotomy now does. Dr. Alexander said the endeavour should be to diagnose and remove intestinal cancer early, and to perfect our methods of suture of the bowels so as to do it with more safety than at present. Palliative operations, on the other hand, are only justifiable by urgent necessity, they cannot arrest the fatal course of the disease, and although they sometimes relieve, not unfrequently they make the last state of the patient worse than the first.

Dr. **Carter** said he would confine his remarks to pyloric cancer and its treatment, and that these remarks should be founded on his own references only, as he believed that in the practical affairs of life the judgment was much more influenced by what one had actually seen and done than by statistical statements of the seeings and doings of other people. After relating three cases of pylorectomy with two deaths and one recovery, Dr. Carter went on to say that unfortunately he could not share the hopes just expressed by Dr. Alexander that we should soon have the means of accurate diagnosis at such an early stage as would permit of operation being undertaken before extension and adhesion of the growth should render its results doubtful. The grounds for such early diagnosis hitherto suggested were absolutely unreliable. The absence of hydrochloric acid from the gastric secretion as suggested by Van der Hadden the presence of enlarged inguinal glands as mentioned by Jaccoud; or of enlarged subclavicular glands as relied upon by Henoch were untrustworthy guides; and we had to wait for the appearance of a tumour with the conviction that in nearly all cases operation would then be too late; and he himself did not look forward with any degree of confidence to a near future in which either the patient would be willing to submit to abdominal section, and the surgeon would be willing to undertake that operation for the mere purpose of clearing up a doubtful diagnosis.

Mr. **Robert Jones** had very little faith in the utility of gastrostomy and gastro-enterostomy. He however differed with Mr. Banks by believing that a distinct future was in store for pylorectomy. The point of clinical value to the surgeon was that the glands in connection with the pylorus were not early affected in cancer.

Mr. **Paul** said that palliative operations for the relief of cancer of the alimentary canal were of much less importance than radical operations, and in the future would probably to a large extent be replaced by them. In cancer of the œsophagus so long as the way could be kept open by a bougie he never advised gastrostomy, but when the patient was starving he thought there could be no question that an operation successfully performed afforded relief. In cancer of the stomach, when a physician suspected the disease, he should allow a surgeon to make an exploration as this was the only means by which an early diagnosis could be certainly made, and a small exploratory incision had never in his experience led to harmful results. When surgeons had more experience in operating on early cases of pyloric cancer, pylorectomy would become an established success, gastro-enterostomy he considered still *sub judice*. There were certain objections to Senn's method which he tried to overcome by a method previously submitted to the Society. Cancer of the bowel above the rectum he could speak of with more confidence as he had performed colectomy six times. The first three patients died, but the last three, owing to an improved method, all recovered. Colectomy had yielded him much greater satisfaction than Mr. Banks, but he much preferred to excise the rectum or part of the colon than simply to adopt the palliative treatment of colotomy, in fact he felt sure there was a good future for both pylorectomy and colotomy.

Mr. **Mitchell Banks** gave details of four cases of gastrostomy, two cases of gastro-enterostomy, and seventeen cases of colotomy. He had come to the conclusion that he would not perform gastrostomy any more, as the condition of the patients was most deplorable. In cancer of the stomach and œsophagus he thought that the patients' sufferings were in many cases coloured too darkly, for he had often seen people die from phthisis and heart disease whose distress was even greater. Not having any personal experience of pylorectomy he could only say that at present it seemed as if the cases suitable for it were so very rare that gastro-enterostomy would for the present be the most useful procedure in well selected cases. He entirely objected to the surgeons throwing upon the physicians the responsibility of their want of success because the latter do not hand over cases sufficiently early. If it is difficult to get patients with cancer of the mouth and breast (which are visible and tangible) to come early enough, how much more difficult will it always be to get them to submit to operation when there is nothing to be seen or felt! One cannot subject every case of severe dyspepsia to laparotomy, so long as the impossibility remains of diagnosing whether its cause is simple or malignant. On the other hand he would urge the more frequent performance of exploratory operations to determine whether anything can be done or not. What he desired to see was a less purely mechanical and a more philosophical way of looking at cancer of the abdominal intestinal tract. The sole question at present about any one of the operations under discussion seemed to be whether it was anatomically possible, and what was the best technique to be employed, while too little regard was paid to the general condition of the patient and his power of resisting the shock of a severe operation or to the possible value of the operation to him, even if successful. He thought it a very unfortunate matter that in the present day surgeons seemed only to bring forward their brilliant and successful cases in journals and at societies, while too little information was given about their failures. The result was that the general medical public conceived a most erroneous view of the value of many surgical proceedings, while the compiling of statistics from such sources was most misleading, and could give no sound basis from which to form a useful formula as to their worth. He would be one of the last to throw any obstacle in the way of the advance of legitimate surgery, and personally had always struggled to keep abreast of the times, but he desired to put in a plea for more judgment and care in the selection of appropriate cases for the operations under discussion, so that the reproach of recklessness and want of regard for human life which had too often stained the annals of Continental surgery might never attach itself to the work of Englishmen.

Messrs. Barr, A. Davidson, Glynn, A. Hamilton, Larkin, Rawdon, Stansfield, and others also took part in the discussion.

Strangulated Hernia.

At the Société de Chirurgie M. Chaput read the history of two cases of strangulated hernia complicated with gangrene. The first was that of a woman, æt. 50, who suffered for five days from strangulation of a voluminous umbilical hernia; fæcal vomiting and collapse had already set in when seen by one of his *confrères*, who immediately practised a long median incision and opened the sac, giving issue to a quantity of fœtid liquid. The protruding omentum was resected and the intestinal folds detached from their adherences, on one of which a long ribbon of gangrene was discovered. By pinching up this portion of the intestine and turning the diseased part inside, leaving to Nature the care of discharging it, the operator sutured the edges of the artificial fold together and completed the operation in the usual manner. The second case reported by the same surgeon was that of a strangulated crural hernia in a woman, æt. 58, and operated on the sixth day. At first taxis was tried, but it was soon evident that an operation was necessary. The strangulated intestine was found to be sphacelated to an extent of four inches, and became detached on very gentle traction. Both ends were sutured and the intestine returned. A stercoral fistula was the immediate result, but in a few days it closed spontaneously, and in three weeks after the operation the patient was quite well.

In reflecting on the case, M. Chaput said that taxis in such cases was bad surgery, and should be absolutely proscribed. A few weeks previously he was called to a man, æt. 50, who had a right inguinal hernia strangulated. Trying taxis, to his satisfaction he succeeded in reducing the hernia, but the following day his colleague was obliged to operate, as the hernia had returned. The intestine being sphacelated to a certain extent, an artificial anus was made, but the patient sank in a few days from exhaustion. M. Chaput said that if he had not tried the taxis, but operated, the man would have recovered. One of the most difficult questions, continued the speaker, in surgical therapeutics was to decide between suture of the intestine and artificial anus. The creation of an artificial anus is extremely simple, and can be effected with ease and without aid or chloroform. It presents the considerable advantage of emptying rapidly the upper end of the intestine of products which contribute to poison the organism, but it presents, on the other hand, numerous disadvantages, resulting from the flow of matter, which provokes frequently the development of phlegmon of the walls, inoculating the peritoneum, forming septic thrombosis of the femoral vein with pulmonary embolus and death, as has happened in some cases to his knowledge. The mortality in any case of this operation is placed by a very high authority at 76 per cent., and even if he patient survives all complications he remains afflicted with a disgusting infirmity which cannot be cured but by a series of grave operations.

Resection, on the other hand, followed by suture of the intestine, does not present the same drawbacks; the mortality is less, and the operation susceptible of being rendered much easier to perform. It is true that with the suture secondary gangrene or perforation of the upper end s to be dreaded, but this accident can be avoided *à la* *rigueur* by not reducing the intestine, and if gangrene supervenes an artificial anus can be made.

Berlin, March 23rd.

Tissue Juices and Therapeutics.

At the last meeting of the Medical Society, Hr. Fürbringer gave an address on Treatment by Organic Extracts, excluding however bacterial products and blood serum. In the first rank stood glandular material which was indispensable in our economy and for the blood. At present the predominant view was that the glands were antidotic; they carried away the poisons from the blood, rendered them harmless, and thereby prevented auto-intoxication. There were two principal representatives of this group that had caused a good deal of lively commotion, and had already been the cause of a good deal of literature. The first was spernum or testicular extract, and the second thyroid extract or juice. After these came pancreatic juice and nerve substance, and lately attempts at treatment had been made with nephrine and cardine. As regards spernum he had already in the year 1891 given an address on the value of the Brown-Séquard treatment of impotence, and had arrived at the conclusion that as regards the regenerating power of the remedy in old men, and its potential action in the sexually weak, there was nothing at all. His prophecy of an early death for the method of treatment was premature however, for there followed a brilliant series of further reports of wonderful successes proceeding from the Brown-Séquard method in France.

The failures in Germany Brown-Séquard explained as the resultant of the misfavour of the experimentors, &c. More than 1,200 of Brown-Séquard's pupils had employed the remedy more than 200,000 times without doing harm, and had obtained wonderful results with it in paralysis, tabes, epilepsy, neurasthenia, and even in tuberculosis, cancer, malaria, &c. How extensively the remedy was used in Germany was shown by the fact that there were then several depôts there that obtained their Séquardine from Paris and distributed it. The active principle according to its discoverer, circulated in all the tissues of the male animal. In 1886 Mattei had already published a similar report on the action of sperma. Montané pleaded for the introduction of the remedy *per oz.* It was further reported by Pliny that impotent Romans and Greeks had fed on the testicles and sperm of asses.

As regards belief of its usefulness in impotency, that had already diminished considerably. Various authors spoke of suggestive action, especially Massalongo and Féré. The latter could not prove that any benefit had ever accrued from the use of Brown-Séquard's fluid in epilepsy. He reported the case of one of his patients who suffered from relative impotence, who, in order to increase the quantity of sperma in the blood, frequently practised incomplete masturbation. This patient became gradually completely impotent. Brown-Séquard denied that he had recommended this procedure, and said that he only meant contact with young women and kissing them. With Pöhl of St. Petersburg the movement again passed into a channel worthy of consideration. It was known that sperm crystals, of which material Pöhl's sperma was composed, were nothing more than the prostatic crystals of Fürbringer, and the cause of the odour of sperma. It had been shown in recent years that spermine was by no means identical with piperazine; on the other hand, it had been determined that Schering's piperazine was completely identical with Ladenburg's æthylenimine, or diathylendiamine. As regarded the clinical achievements of Pöhl's spermine, they were identical with those of Brown-Séquard's testicular fluid, only the Russians had been a little more critical. Pöhl had asserted that spermine was a constituent of all other parts of the body, and that therefore it must act wherever the quantity of spermine in an organ was below the normal. According to Gautier, it was a leucomaine with a special function. The latest construction of Pöhl was very remarkable; he based it on the magnesium experiment. As very small quantities of spermine sufficed to oxidise the metal in large quantities, Pöhl assumed that a catalytic action took place, in spite of intra-organic oxidation. He therefore recommended the remedy in all diseases in which oxidation of the blood was deficient, such as auto-intoxication, diabetes, anæmia, cachexia, neurasthenia, &c. He claimed to have proved that the nitrogen in the urine was greater than when no spermine was taken. As to a catalytic action of the drug during life, the speaker had made experiments on which he would report later.

Austria.

[From our own Correspondent.]

Vienna, March 23rd.

Carcinoma Œsophagi.

At the Gesellschaft, Ullmann showed a man, æt. 62, on whom he had operated for carcinoma of the œsophagus with apparent success. In order to close the fistula the stomach was slightly twisted and fastened in the wound as advised by Gersung.

Foreign Bodies.

Topolanski showed a man who got a stroke on the eye in 1872 with a piece of iron, some of the fine particles penetrating the outer coverings. One large piece of iron could be seen in the anterior chamber when the patient lowered the head, evidently having been there for twenty-two years.

Lens Removal for Myopia.

Two cases that had been operated on a few years ago were brought forward to show the utility of ophthalmic surgery.

Prof. Schreiber, at the last Heidelberg Congress, endeavoured to give a new impetus to this operation, but Topolanski thought a very strong point against the operation was the dissatisfied state of the patient ever after. In both cases the eyes were hypermetropic and saw as presbyopic with glasses. Instead of the extraction operation he thought the "discission" should be practised.

Laryngeal Tuberculosis.

Hajek gave an exhaustive description of having successfully cured a case of laryngeal tuberculosis after having removed the morbid epiglottis which he considered rarely accomplished by endo-laryngeal surgery. The patient came to the policlinic in July, 1893, after two years' treatment in various institutions for laryngeal tuberculosis. He was feeble, weak, and greatly emaciated at this time with great difficulty and pain in throat.

The laryngoscope revealed a wide area of inflammation, over-hanging epiglottis and ulceration. The ulcerative surfaces were covered with white granulation cells as usually exist in tuberculosis. The aryepiglottic folds were one mass of intumescence. After cocainising, insufflations of iodoform and morphia, &c., no relief was obtained, and Hajek was induced to perform endo-laryngeal extirpation. It was removed in two portions by means of the snare by which means the hæmorrhage was easily controlled, and the patient retained eight days in the Policlinic. The carbolic spray (one per cent.) and iron pills were the after medicaments. After his dismissal from hospital the surface was regularly bathed with an 80 per cent. of lactic acid solution till cicatrisation was complete, after five weeks. Other infiltrations were treated in a similar manner with the lactic acid. A tubercular sore took place on the left angle of the mouth, as well as a lupous eruption on the face, and was healed by the acid. It might be assumed that the ulceration in the larynx was of a lupoid character, but the circumscribed notes with the peculiar appearance and infiltration was strong presumption of tuberculosis. The operation was not of large magnitude as the epiglottis has no large trunk vessels to stem.

Krankenhaus Extension.

Again the want of space for this Institution was brought before the House of Parliament when discussing the budget, but the proposition of Menger and Beer was lost by a very small majority, who asked the privilege of Alserkaserna to the now extensive Alg. Krankenhaus. The necessity of extending the accommodation of other medical schools in the empire was discussed as well as the propriety of teaching medicine in Italian at Innsbruck.

◆

The Operating Theatres.

ST. MARY'S HOSPITAL.

Enlargement of a Colotomy Opening.—The case in which left inguinal colotomy had been performed some two years previously by Mr. Norton, and which by cicatrisation of the parts around the aperture had become sufficiently constricted to be a cause of obstinate constipation, was operated on by the same surgeon for enlargement of the aperture. The first operation was on account of sudden and acute obstruction of the bowels due to the presence of a large tumour in the pelvis, probably fibrous, situated on the right side of the rectum and immovably fixed. When the patient first came under observation the abdominal cavity was highly distended by the flatus, and the pulse was scarcely to be felt. Immediate operation was a necessity, and as above stated left inguinal colotomy was performed, from which the woman, æt. about 50, made an excellent recovery. The artificial anus had not been a source of much trouble to her as the fæcal escape had been prevented by the application of a plug in the shape of an infant's bottle teat supported by a pad. The present operation was performed in the following manner:—The mucous membrane was encircled by an incision which separated it from the cicatricial tissue and freely drawn up out of the wound; then the cicatrix in the line of the original operation was carefully dissected down to a depth free of all hard tissue, and the finger was then inserted to feel that the gut was no longer pressed upon. In doing this a few fibres of hardened tendon in the deeper parts were found to be largely a cause of the obstruction, and these having been cut through, the mucous membrane which had been freed at the commencement of the operation was drawn laterally and fixed in the new wound; it was found that the aperture into the gut admitted the thumb without difficulty. Mr. Norton remarked that in counteracting the constriction of such an aperture it would be, of course, impossible to carry the knife at once through the constriction and so dilate the aperture to the extent required, and that for two reasons; first, because on penetrating the mucous membrane of the gut there would certainly be danger of entering the peritoneal cavity; and secondly, such an incision would heal up to its former constriction; therefore, the only way that the aperture could be successfully dilated was the manner in which the operation had been performed.

MIDDLESEX HOSPITAL.

Ventral Hernia occurring in the Scar of an Old Operation.—Mr. **Hulke** operated on a woman, æt. 40, the subject of a ventral hernia presenting through the scar of an old abdominal operation. The hernia had become so large and troublesome that it absolutely prevented the woman from following her occupation. After cutting down and opening the sac it was found necessary to remove a considerable quantity of omentum, there were no adhesions however; the sac itself which was multilocular was cut away on a level with its wide neck; the cut peritoneal surfaces being brought together by strong deep sutures, another row of smaller sutures was put through the muscular fibres of the rectus, and finally the skin wound united after a good deal of the redundant integument had been snipped away by the scissors. Mr. Hulke remarked on the tedious length of the operation, but gave a very graphic demonstration on the blackboard of the way in which he had dealt with the sac.

Removal of Breast for Soft Rapidly Growing Scirrhus.—Mr. **Pearce Gould** operated on a very fat woman whose left breast was affected with a soft rapidly growing scirrhus. Mr. Gould's incision for the removal was vertical, and he demonstrated during the operation the ease with which he took away all the glands from the axilla without making any incision in that region, this was done by pulling the external flap outwards, the glands being freed by the finger and the knife, and being eventually taken out attached to the breast, the lymphatic attachment from them to the mamma being kept intact; the wrist of the patient was kept under her neck during the operation. The hæmorrhage which was free was entirely arrested by torsion; the wound was sewn up by the continuous suture, no drainage was employed, adhesive plaster being tightly applied over the first light dressings to keep everything in apposition.

UNIVERSITY COLLEGE HOSPITAL.

Soft Infiltrating Sarcoma growing on and around a Rib.—Mr. **Barker** operated on a man, æt. 44, who, some months ago, had received a blow on his left side from a cricket ball. He had noticed a lump in the situation of the blow for the last two or three months; there was no history of tubercular disease nor of syphilis, therefore, as Mr. Barker remarked, the swelling was probably a new growth affecting the rib; it could not be a gumma nor an abscess bursting from within; it was about the situation of the tenth rib; it might, he thought, be necessary to take away a piece of the rib. The surgeon made an incision of about six inches long following the course of the rib and going across the tumour; he dissected down by the careful use of the fingers, the knife, blunt scissors, and of the periosteal elevator; but after exploration he said he did not think he should be able to get away all the growth, as he should probably be carried through the diaphragm, the tumour having a tendency to infiltrate all parts around it. He took away the outlying lobe of the growth with comparative ease, although it was adherent to the rib. Mr. Barker remarked that what he had done was practically little more than an exploration; the growth, he pointed out, went through the ribs to the diaphragm, and if he pursued it more than he had done there would be considerable danger to the patient's life, and this risk, he thought, the surgeon was not justified in taking.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MARCH 28, 1894.

A PLEA FOR SYMPHYSIOTOMY.

THE discussion on a paper bearing this title by Dr. Harris, of Philadelphia, at the last meeting of the Obstetrical Society, an account of which we publish elsewhere, shows that this operation, which has been disinterred from oblivion within the last year or two by sundry enterprising Continental surgeons, is far from having acquired the freedom of the obstetrical world, or at any rate of that portion of it which inhabits the United Kingdom. Dr. Harris wonders why it has not "taken on," but perhaps when he reads the report of the discussion he will understand why this is the case. The most remarkable feature about the discussion was that each speaker seemed to ignore the remarks that had fallen from those who had preceded him. Dr. Lewers explained on the one hand how the erroneous impression had gained ground that not more than one inch could be gained by division of the symphysis pubis, viz., that the experiments upon which the measurements were taken were carried out on the bodies of women who had not actually died in labour. As might be expected, the amount of space thus gained differs greatly according as the subject was or was not in labour at the time of death. Yet this question of measurements was brought up again and again and dissected as minutely as if it had not already been threshed out. Symphysiotomy, we are told, is indicated in cases of moderate constriction of the pelvis, cases in which the conjugate diameter does not fall below two and three-quarter inches. Most practitioners would probably prefer to try what they could do with the forceps or turning, but however favourable to the mother, the results of either procedure in respect of the child's life are of course likely to be disastrous. Dr. Lewers said, it is true, that the operation was specially adapted for cases in which labour was advanced. By this we presume he meant after the escape of the amniotic fluid, for in the event of a very narrow conjugate the head must still be above the brim, or at most but slightly engaged. At this stage the forceps having failed, and turning no longer being available, the only alternatives, if the child's life be taken into account, are Cæsarian section and symphysiotomy. In hospital, with the requisite skill and appliances, the former gives results which compare favourably with symphysiotomy, but we doubt whether this is likely to be the case in general practice, in fact, we commonly see practitioners deliberately sacrifice the child rather than subject the mother to the risks inseparable from Cæsarian section, especially in the hands of inexperienced operators, and in order to appease any scruples about killing the fœtus, operative interference of a drastic kind is frequently postponed until it may be supposed to be dead, thereby exposing the mother to the grave dangers inseparable from an exhausting and protracted labour. There can be little doubt that symphysiotomy is not only a less dangerous operation than Cæsarian section, but is less likely to frighten the friends and the practitioner, very few of whom would be prepared to incur the grave moral responsibility of such an operation. It is as yet too early to attempt to deduce the real mortality of the operation. The proportion of fatal cases is rapidly diminishing all over the world, and the figures at present available cannot be accepted as a fair estimate of the necessary mortality following symphysiotomy, seeing that most of the operations have been performed by men whose experience of the procedure was *nil*, and who were constrained to take the published descriptions of the operation as their sole guide. If symphysiotomy does not conquer for itself a place in the obstetrical arsenal it will be mainly because when friends are called upon to decide between additional risk to the mother and safety for the child, they usually decide without hesitation in favour of the former, and few will gainsay the humanity of such a course in view of the relative social values of the two lives. There are, however, cases in which the life of the child possesses exceptional importance, and in such cases, provided the conjugate diameter is not unduly impinged upon, and provided always that the fœtus is living, symphysiotomy will be indicated. If, however, it is to be restricted to these cases its utility will be insignificant.

◆

THE EMEUTE OF DUBLIN STUDENTS.

The effervescence of dissatisfaction on the part of the students of the Irish College of Surgeons shows no sign of abatement, and we are sorry to say that the agitation is not being conducted on their part with that tact and calmness which we have earnestly counselled. When we last wrote, the Council of the College had agreed to meet the representatives of the students and to talk over their complaints quietly and reasonably. The conference took place on Monday the 19th, and, in the next morning's papers, an inaccurate report appeared, which wound up with the statement that a subsequent meeting of the students had been held and that a threatening notice had been agreed to, to the effect that all students should pledge themselves to resort for their summer lectures to other schools until the College shall accede to their demands. In the interest of the students themselves we say that the publication of this report and threat was one of those blunders which was worse than a crime. We are quite certain that the Council of the College never contemplated the communication to the newspapers of the conversation which took place at one of the private committees, and that it would never have invited the students to conference if it had thought that the occasion was about to be used for such purpose. Moreover, we are equally certain that if the members of the Committee had suspected that there was someone present noting down their words, they would have been much less candid and the interview much less satisfactory, and it is only natural to conclude that the course pursued by the students on this occasion will have the effect of making the Council less willing to yield to their demands, and certainly less ready to enter into friendly conference with them in future. We ought not, and do not, hold the students responsible for a large quantity of nonsense written in the newspapers by irresponsible correspondents, who seem to know as little of their subject as of the discreet method of conducting such a controversy, but we may remind them that it is unwise to make threats which the organisers are unable to carry into effect, and that it is scarcely in their power, at a moment's notice, to "boycott" the Royal College of Surgeons in Ireland. Parents who pay the lecture fees, and hospital surgeons and teachers who advise parents in such matters, will have something to say before their sons run off to a new centre of teaching; moreover, those who give utterance to this threat ought to recollect that, if they should be able to carry it into effect, they would only succeed in damaging the Professors of the Coll[illegible] School who receive the lecture fees, and who have nothing whatever to say to the subject of complaint, and would not, in the least, inconvenience the College, which does not profit to the extent of one shilling from the student's lecture fees. As we wish well to the organisation of students in Dublin and elsewhere for protection of their own interests, which have long been insufficiently regarded for want of such organisation, we do not hesitate to warn them that this method of doing business won't pay. The "skittishness" of the student has always marred such movements. If they mean to produce a lasting result they must deal with their grievances as men, not as schoolboys—must ask nothing but what is attainable, and must seek to get it, as men would, not by making noise, breaking glass, and fulminating ridiculous threats which they are powerless to enforce, but by adducing solid reasons and talking quiet sense.

As to the grievances which the students have formulated on this occasion we should say a few words. These grievances are—(*a*) That a new rule has been published by the Conjoint Examination Committee to the effect that candidates rejected in a subject may be sent back, not only for re-examination in that subject, but for a further course of study therein, which would block the student in his professional progress. As to this, we have already expressed our sympathy with the student, and the hope that the rule will not be enforced, as it is bad both in principle and in practice. It is not, however, the rule of the Colleges, nor have they any power to refuse it. It is one of those evolutions of the impractical theorists of the General Medical Council, which can be enforced with much advantage when we reside in Utopia, and it will be quite time enough for the students to cry out when the Examination Committee puts it in action. In eight years the Committee has done so only in two instances, and, though it is obliged to promulgate the rule, we have no reason to suppose that it has any intention of compelling the examiners to use it. (*b*) That the examination fees are too high. In this contention there seems to be a general agreement, but the grievance is not so bad as it looks. The difference between the Dublin diploma fee of £42 and that of Edinburgh, £26 5s., looks considerable, but when it is borne in mind that the extra £16 is spread over at least five years it can scarcely be supposed that the additional impost of £3 4s. a year has much influence in determining the ultimate destination of the Irish student. It is, however, manifest that, in any case, a change cannot be effected in a moment, as the students seem to expect, inasmuch as the College of Surgeons has to make its own mind up and then to consult its Physician partner, and it is by no means certain there will be an agreement between the partners on the matter. Supposing that such agreement were effected, the realisation of the change would take at least three months, and, even then, it would be questionable whether students who entered under the existing contract should or could be allowed to parti cipate. Nothing shows the weakness of the student's information on such subjects, and his want of discretion, more than the declaration that the College must be "boycotted" because it could not give any definite answer on such a question in time for the April examinations. (*c*) That the re-examination fee shall be reduced from three guineas to one. The answer to this demand is simple. It is wrong that the Colleges should make any profit out of re-examinations (because in that case there might be an inducement in the examiners to send the candidate back), but it is also wrong that the Colleges should lose by the idleness or misfortune of the student. Therefore the equity of the thing is that the student should pay whatever the re-examination costs. But upon this there is a complete misapprehension. It is quite a mistake to suppose that a profit has been made by the Colleges upon re-examinations taken as a whole. When the re-examination was in one subject only, the Colleges certainly made a big profit, because they had to pay only two examiners, but when the examinations covered a group of subjects we believe that the fees to the six or eight examiners employed often amounted to more than the three guineas paid by the student, and the Colleges lost by the transaction. Regarded as a penalty on ignorance, the three guineas may also not be without its uses, for it is notorious that when the re-examination fee was on the lower scale, numerous candidates were found willing to "throw a guinea at the exam." and offer themselves without preparation on the off-chance of success. The other of the students' grievances are matters of detail and need not be discussed.

◆

PRIMITIVE TREPHINING.

An interesting contribution on primitive trephining is published in the last number of the *Bulletin of the John Hopkins Hospital.* It deals with the Muniz Peruvian collection of specimens which was exhibited at the World's Congress of Anthropology, held in connection with the Chicago Columbian Exhibition. The collection comprises nineteen skulls, representing those which were found to have undergone trephining out of a number of 1,000 skulls collected. It is worthy of note that the specimens largely tell their own story, and about half of them indicate the manner in which the operation was performed. Three types of operation are exemplified. In the first type four linear incisions were made in the cranium in parallel pairs intersecting each other at right angles so as to form a rectangular button, the incisions being narrow, V-shaped in cross section, and gradually increasing in depth from ends to centre, thus indicating that the instrument was a pointed bit of stone or arrow-head held vertically and operated by reciprocal motion. This type of operation is rude, and the resulting traumatism is jagged, each incision extending, perhaps, half an inch beyond the button at each extremity. There is no indication of the purpose of this type in any case, and nothing to suggest that if the operation was ante-mortem the individual survived. In the second type of operation the incision was evidently made also by a rudely-pointed instrument, probably of stone, held vertically and moved reciprocally; but as cutting reached and penetrated the inner table, the area of incision was moved forward and at the same time the direction of the sawing was changed so as to produce a rudely carved cut, and, when two such incisions were made, an irregularly elliptical button. The third type of operation was performed largely or wholly by scraping in such manner as to remove the outer table and diploë, and reduce the inner table to a feather edge. It is important to mention that several of the specimens showed that the patients had not survived the operations, one of them probably for a long time after two trephinings, but apparently dying about the time of the completion of the third. There was evidence pointing to the assumption that not all the operations had been performed for the relief of surgical conditions, although several examples were exceptionally noteworthy as proving that this had been the object in view. Among the examples of the latter was a cranium showing a depressed fracture of the left temple, such as might have been produced by impact of a sling-stone or blow from a spiked club, which are known to have been the weapons used among the ancient Peruvians. In this case the patient had plainly succumbed, probably during the operation. Another specimen showed a similar fracture in the posterior part of the left parietal, and again death seems to have immediately taken place. A third specimen displays a compound fracture involving the left temporal suture; the result, however, was the same as in the previous cases. Perhaps the most interesting specimen of all was a cranium in which the ankylosis of the sutures so far progressed as to indicate an age of twenty-five or thirty years, while the development of the teeth indicated an age not exceeding twelve years. The trephine operation was of remarkable size, extending from the frontal within three-quarters of an inch of the orbital cavity across the coronal suture nearly to the centre of the parietal, its length being fully four inches, and the width averaging an inch. In this case, the only one, a silver plate was known to have been used, having been found in position over the aperture in the mummy case. The presence of the plate, its seat in the skull, showed long wear, and the absorption and reparative growth all indicated that the operation was survived. The condition of synostosis present in this prehistoric skull was very interesting, and the trephining operation performed is suggestive of the operation of craniectomy as practised in the present day. Dr. W. J. McGee, the author of this valuable paper, concludes as follows:—"On the whole, the Munz Collection, which is by far the largest and most instructive assemblage of specimens of primitive trephining thus far brought together, is of special note in that it demonstrates certain points heretofore obscure with respect to primitive trephining. The most important conclusions are: (1) that the operation was ante-mortem, since five individuals out of nineteen represented certainly, and two or three more, probably survived one or more operations; (2) hat the trephining was surgical—two provisional deductions are also indicated by the collection; (3) that the operation was used in a medical way to relieve a general pathological condition; and (4) that the operation was, as indicated by the total absence of marks of metallic instruments, anterior in date to the Spanish invasion, and thus essentially prehistoric.

◆

Notes on Current Topics.

The Government and the New University Scheme.

Mr. Asquith stated in the House of Commons last week that the recommendations of the Royal Commission on the Gresham University draft charter were receiving the careful attention of the Government; but the question as to whether the Government would bring in a Bill to give effect to the recommendations must depend to some extent upon the unanimity shown by the different bodies interested in accepting them. So far the opposition has been mainly displayed by the existing University, the leading members of which must be held to know best in what particulars the scheme is mostly at fault. It is of interest to note that the following resolutions will be submitted to a special meeting of Convocation on April 10th next:—(1) That Convocation protests against the withdrawal without its consent of the charter of the University of London as proposed by the Gresham Commission, and notes with satisfaction that the Commission quotes and does not dissent from the praise which the Commission of 1888 accorded to the University in respect of the manner in which it has fulfilled all the functions hitherto entrusted to it. (2) That Convocation reaffirms its desire that power should be conferred on the University to make better provision for teaching, for the advancement of learning, and for original research in London according to the schemes of 1886 and 1893 adopted by Convocation or with modifications thereof. (3) That Convocation is of opinion that the scheme recommended by the Gresham Commisson does not contain sufficiently definite proposals for increasing efficient teaching in the Metropolis, would tend to destroy the present work of the University, and would operate injuriously on higher education throughout the Empire. (4) Convocation, therefore, although it would regret the establishment of a second University in London, is of opinion that it would be less disastrous to establish such a University with a distinctive title than to carry into effect the scheme of the Gresham Commission.

Paper Handkerchiefs for Consumptives.

The amount of phthisical infection conveyed to the laundry in the clothing and linen of consumptive patients must be in the aggregate something enormous. Fortunately, no doubt, the greater number of the specific bacilli are destroyed in the process of washing. Nevertheless, there can be little doubt that infection is at times spread from the laundry. Handkerchiefs are specially liable to be charged with phthisical sputa. There can be no excuse, however, at this time of day, for sending handkerchiefs to the wash charged in this way with dangerous seeds of disease. Long ago the use of soft paper handkerchiefs, sent from Japan, was introduced to the profession. They can be procured at trifling expense, at a less cost, indeed, than that incurred for the washing of an ordinary linen handkerchief. The paper substitute can be burned when done with, and the disease germs are thus effectually disposed of. Nothing can be more distressing to the zealous sanitarian than the reckless way in which the specific poison of phthisis is scattered broadcast among our communities. Prompt and absolute disinfection or destruction of all excreta should be the rule in all cases of consumption. Before we can hope to reach such a stage of enlightenment, however, the popular mind will have to be educated up to the requisite pitch. A crusade against so terrible a scourge as consumption might well be included within the scheme of any lay newspaper boasting of an advanced social programme.

Mr. Gladstone.

The truth respecting Mr. Gladstone's eyesight has at last been made public, and the ophthalmic surgeon under whose care the ex-Premier has placed himself is Mr. Nettleship. We understand that Mr. Nettleship was recommended to the aged statesman by Sir James Paget, who is a personal friend of Mr. Gladstone's. The rumour that cataract was present in each of Mr. Gladstone's eyes is confirmed, and there consequently remains nothing more to be done than extraction of the lens from one or both eyes, in order to restore vision. Report states, however, that no operative interference will be undertaken until the lapse of six months. Probably this course has been decided on with the view of allowing the good effects of rest from the anxious cares of the leadership of his party to become more manifest in Mr. Gladstone's health.

The Coronership for North-East London.

The contest for the important post of Coroner for North-East London is proceeding apace. Since our last issue several more candidates have come forward, among whom are three or four other medical men. The salary attaching to the post is sufficiently attractive to induce capable men to come forward, and it is quite certain that whoever the candidate may be who is successful in the election, the County Council will have done its duty in selecting the best man. As, however, we have always pointed out, a medical man possessing the advantage of having been called to the bar is the one whose qualifications for such a post as that of a coroner are the best. We must, therefore, repeat the hope that the County Council will give due weight to this important point when considering the claims of the various candidates.

The Officers of the Army Medical Staff in Ireland, under the presidency of Surgeon-Colonel Maunsell, are about to entertain Surgeon-Major-General Collis at a farewell dinner in the Ancient Concert Rooms on the occasion of his retirement from the position of Principal Medical Officer for Ireland.

The Lewisham Lunacy Inquiry.

The protracted inquiry into the accusations brought by Joseph Mariano Williams, a journalist, against the Lewisham Workhouse and Asylum authorities has resulted in a report which we print in full in another part of the Medical Press. It will be seen that the charges are refuted so far as the asylum is concerned, but that irregularities are shown to have taken place in the workhouse. One will be interested to learn the upshot of this report in the case of the officials of the latter institution.

The National Lying-in Hospital, Dublin.

This Hospital, which has been practically closed during the illness and since the death of the late Professor Roe, has been re-organised and re-opened under auspicious circumstances. Dr. P. J. Barry, formerly Assistant Master of the Coombe Hospital, and Dr. Andrew Horne, formerly Assistant Physician to the Rotunda, are its chief medical officers, and, though open to patients of all religious denominations, it will be under the special patronage and administration of Archbishop Walsh and the heads of the Catholic Church.

The late Medical Officer of Bristol.

The death has been announced of Dr. David Davies, who formerly filled the post of Medical Officer of Health for Bristol. As a result of 21 years of active official work he succeeded in rendering the large and important city which he served one of the healthiest in the Kingdom. This result was in no small degree remarkable, for Bristol, in spite of many modern improvements, still retains many of the drawbacks of an ancient fortified city, with its dense population, its narrow streets, and its slum tenements. Dr. Davies was a most popular citizen, and some years since was created a Justice of the Peace. He died at the ripe age of 76. His son, Dr. D. S. Davies, has for some time ably filled the post of Medical Officer of Health for Bristol.

A New Qualification in Irish Lunacy.

The election of an Assistant at the Carlow District Asylum, in substitution for the Visiting Physician (abolished to please the Residents), was attempted a fortnight since, and proved abortive, the votes being six to six. The race resulted, in fact, in a dead-heat between the Protestant landlord party and the Catholic Nationalist party, and if either of the candidates had been the greatest psychologist of the age, and the other the greatest booby on record, we imagine the result would have been exactly the same. Our purpose in noticing the contemptible little politico-religious wrangle is to object to the theory urged on behalf of one of the candidates, that he was specially qualified in psychology because he had attended a course of lectures on the subject, and had been questioned in the subject at his examination. This is, indeed, a special qualification of homœopathic dimensions, and, so far as it goes, the candidate should have the benefit of it, but, lest the same claim should be put in hereafter for other asylum appointments, we desire to record the opinion of the profession, as we estimate it, that the only person who can advance a special claim to appointment in an asylum is the man who has seen service in an asylum, and that all other candidates are practically on equal ground. We are not willing to see a twopenny course of lectures represented as a special qualification and perhaps put forth at a future time as a good reason for ousting a specially educated asylum officer from the promotion to which he is specially entitled.

The Eighth International Ophthalmological Congress.

The date fixed for the forthcoming International Ophthalmological Congress at Edinburgh is the second week in August. It is announced that owing to the death of Professor Donders, who has presided on previous occasions, the presidency will be entrusted to Dr. Argyll Robertson. Upwards of two hundred oculists, British and foreign, have intimated their intention of taking part in the proceedings. Intending visitors are requested to communicate at once with the General Secretary, Dr. Berry. The subscription is £1, and members receive a copy of the Transactions, which will not be sold separately. Arrangements are being made for a discussion on "Intra-ocular Therapeutics." It is hardly necessary to refer to the fact that Reception and Entertainment Committees are being organised in order to afford visitors every facility for thoroughly enjoying the social hospitalities and for inspecting the objects of interest in this most ancient and hospitable capital.

The Proposed Veterinary College for Ireland.

The three Principals of the Scotch Veterinary Colleges have issued a circular to members of, and to gentlemen interested in, the veterinary profession with regard to the proposed grant of £15,000 for establishing a similar college in Ireland. The chief burden of their complaint is that their own Colleges, which have been all established and conducted by private enterprise, and which are self-supporting, should have to compete against a Government establishment in Ireland, for they point out that an Irish College endowed by the Government will probably require an annual grant hereafter to keep it on its legs. A note from Lord Rosebery anent the matter points out that the money is not from Imperial sources, and that the foundation of an Irish College was clearly contemplated in Sect. 4 of the Veterinary Surgeons Act of 1881, provision being made to affiliate it to the Royal College of Veterinary Surgeons. We suspect that a very considerable amount of the opposition to the scheme which has arisen in Scotland is due to the fear of a diminution in fees received at the Scotch Colleges from the Irish students, who at present we believe number about 30 per cent. of the total. The Principals, however, in their circular say that they have no objection to the scheme provided the Scotch Colleges are placed on the same footing as regards Government support.

The Government and the Report of the Royal Commissioners on Vaccination.

Mr. Asquith has, to use a hackneyed expression, "climbed down"—in regard to his Bill to amend the Vaccination Act. That redoubtable champion of the idiotic movement against the compulsory clause—Mr. Hopwood, Q.C.—questioned the Home Secretary on the matter in the House of Commons last week. The reply was not reassuring. Mr. Asquith said that after the experience of last session he feared it would be impossible to hope that a bill carrying out the recommendations of the Royal Commission in favour of abolishing repeated prosecutions and ceasing to regard the parents as criminals, would be treated as non-contentious. If the bill was not so treated, there was no chance of it being passed into law this session. This plain statement of fact was probably very distasteful to Mr. Hopwood and his supporters. He and they have doubtless been under the impression for some time that an adherent to their cause had been gained in Mr. Asquith. But the Home Secretary's personal feelings on the subject matter but little. It was entirely a question for the Government to solve, and the Government have decided not to have anything to do with it. This under the circumstances was a very sound conclusion at which to have arrived. There can be no doubt that the day is yet far distant when the House of Commons will stultify itself by amending the Vaccination Act, despite the recommendations contained in the Report of the Royal Commission.

Typhoid Fever at the Guards' Depot, Caterham.

We learn that typhoid fever has for some weeks been prevalent at Caterham among the men of the Guards' Recruiting Depôt. Fourteen or fifteen cases have already occurred, and other suspicious cases remain under observation. Several of the men attacked have died. According to our contemporary, the *United Service Gazette*, the water supply is regarded as being defective, and as the cause of the outbreak. The usual precautions have been adopted, and later accounts tend to show that the local epidemic is subsiding. It is to be trusted, however, that full inquiry will be made into the matter, and that the authorities will lose no time in remedying those defects, whether in the water supply or drainage, which are alleged to be present. It is somewhat hard on healthy young recruits to be consigned to a certain station, and soon afterwards to be called upon to pass through the ordeal of an attack of typhoid fever.

Dr. Lambert Ott alleges that the blood of those who work in breweries and drink nothing but beer, becomes richer in red corpuscles and poorer in white corpuscles than normal blood. When the habit of beer-drinking is suddenly stopped the person loses fat, and the blood changes to the normal corpuscle standard. Beer-drinkers are also stated to acquire an enormous bladder capacity.

The "Eastbourne Lunacy Case."

The new access of zeal displayed by the [illegible] Commissioners in prosecuting those in charge of "sing[illegible] patients" without a licence may be regarded from two very different points of view. That taken by the *Daily Chronicle* may be the natural one for the lay press, but it is not to be commended by the medical press. The *Daily Chronicle* regards it as "desirable that the Lunacy Commissioners should prosecute on the slightest pretext, as otherwise the temptation to overstep the line would be very great, and would easily drift back into some of the horrors of the old private asylums." This is mere sensational pleading, and the writer is utterly ignorant of the matter. His ignorant assumption that "climacteric mania" and temporary nervous disturbance may be bracketed as uncertifiable is delightfully refreshing. We strongly advocate the putting down of abuses; but we repeat what has been said before in our columns, that the action of the Commissioners may be pushed too far, that it should be discriminative and considerate, so that all unnecessary publicity should be avoided, and that nothing should be done to stifle the legitimate treatment of incipient insanity in private houses. So far the action of the Commissioners has not been conspicuously successful, and it is to be hoped that while exercising all diligence in their calling, they will fully recognise that there is a medical and social point of view that must not be disregarded.

Defective Drain-pipes.

A curious case was brought before a London police-court last week, involving the defective laying of some drain-pipes by a workman, and the decision of the bench is certainly not calculated to lessen the difficulties already in the way of sanitary administration. A summons was taken out against a builder and his workman for having so negligently repaired a certain drain-pipe in a dwelling-house that the same was a nuisance and injurious to health. It appeared that the sanitary inspector went to inspect some work which the owner said had been carried out according to instructions. The inspector found a broken drain-pipe, which the builder protested had been put in unknown to him by his workman. The summons against the builder was dismissed, while the workman was fined 40s. The magistrate remarked, as well he might, that the proceedings were in the nature of a novelty. One had always imagined it to be an inflexible precept of English law that the master was responsible for the deeds of the workman acting under his directions. Certainly if the sanitary authorities find they have to prosecute men of straw they will not be anxious to interfere under such unsatisfactory conditions. What could be easier for a master than to lay the blame of defective work on his workman? The latter would be mulcted, on conviction, of a small fine, which his master would immediately pay. We suggest that the juster plan would be to punish both master and servant.

Dr. Leslie Phillips, of Birmingham, who has for some time past occupied the post of Secretary to the Medical Defence Union, has resigned that position.

Eskimo Obstetrics.

The *Brooklyn Medical Journal* for March contains a most interesting communication by Dr. Cook, Surgeon to the Peary Arctic Expedition with reference to the obstetricity of the Greenlanders of the extremest north. The tribe referred to are named the Arctic Highlanders, and they live for nine months of the year in a temperature of 20 to 50 below zero. Girls are married at twelve or thirteen years of age, but do not menstruate until nineteen or twenty, and do not menstruate at all during the long arctic night, four months long in this region, and look forward to the return of sunlight and menstruation to cure all disease. A woman who proves sterile may be cast off by her husband, and pass on to another, until finally the birth of a child becomes a bond of marriage. Very few, the author states, prove sterile. When about to give birth to a child a woman is put in a stone house, or, if this be not obtainable, in a snow hut, absolutely alone. She is given food enough to last two or three weeks, and she gives herself any attention she may. The cord is cut by grinding between pieces of stone, and is tied with sinews. After the cries of the child have been heard by those outside for about a week the house is opened, and visits are received from female friends. Death is a common result of this peculiar custom. Abortions are very rare, and the victim of one is an object of ridicule. Children are nursed by the mothers for five or six years. Diseases of children are few, and mortality among children is small. A little farther south the unfortunate effects of civilisation are seen, contact with missionaries has led to better care of mothers and children, but also to the use of civilised clothing, whisky, coffee, tobacco, tea and sugar, all unsuited to Eskimo manners of life. Two-thirds of these latter people are thought to be tuberculous, while not one case was known in the northern district. An interesting peculiarity is the presence of a layer of blubber beneath the skin in all parts of the body. Pictures of animals, people, &c., shown these people were held upside down, and sketches of animals made by them were made in the same way; but those who had been among the missionaries had lost this habit. This coincides with the theory of the inverted retinal image being mentally reversed, as a result of education. Syphilis is unknown among those who have had no contact with white people, but universal among the others. Sexual intercourse seemed only to take place during the period of sunlight, as at the approach of night the people lost strength, and became chloroanæmic, and the slightest exertion of any kind was fatiguing. This exhaustion in the absence of sunlight was felt by the exploring party also, and led to a condition of great depression.

A Workhouse Scandal.

For some time past the condition of things existing at Newton Abbot Workhouse (Devonshire) has been indignantly commented on at the meetings of the Board of Guardians for the district, and certain members of the Board have again and again insisted on the necessity of a searching inquiry into the irregularities which have been alleged to exist. Hitherto, however, attempts in this direction have met with only partial success; and the continued existence of the abuses complained of has at length led to a full exposure of the whole circumstances of the case by one of the guardians, who has been compelled to take this course in consequence of the failure of his efforts to obtain the necessary reforms by less public means. The whole question came under discussion at the last weekly meeting of the Board, when Dr. Ley, one of the members, read a lengthy communication dealing with the irregularities of the workhouse administration which formed the basis of his complaint. This mainly consisted of a statement, made on oath before a magistrate, by a nurse who had been engaged during the preceding three months in the wards of the workhouse, and whose revelations concerning the manner in which the affairs of that institution have been administered are of the most startling character. If these charges are true, a reckless disregard must have been paid to even the most elementary laws of cleanliness, for it is affirmed that the women coming into the union were sent into the wards unbathed, and commonly remained for a week without any change of the filthy clothing in which they arrived. One of the inmates, who had been resident in the house for twenty-eight years, had, the report stated, never once been bathed throughout all that time; and the most favoured paupers in this connection enjoyed the luxury of a wash only at intervals of two or three weeks. It is not surprising to learn that, as a result of this neglect of the commonest rules of hygiene, the evidences of filth were abundantly present in the shape of lice and other abominations on the bodies of the workhouse inmates; so universal, indeed, were the live attendants on the uncleanly surroundings that even the nurse herself found it impossible to keep her person and clothing entirely free of the loathsome pests. The report contains other charges of gross mismangement on the part of the workhouse officials, and also of certain acts of oppressive cruelty in the treatment of some of the sick inmates which are probably the outcome of the lax discipline that alone could permit of such occurrences as have been described. Poor-law administration is unquestionably surrounded by many difficulties and demands on the part of those who are entrusted with the executive work in connection with it—carefulness, tact, and unwearying devotion to duty; in the absence of these it is altogether impossible that satisfactory results can be achieved; and where they are wanting abuses will necessarily arise, with the direst consequences to the public welfare. It is satisfactory to know that the state of affairs at Newton Abbot will be now completely investigated, the guardians at the meeting referred to having decided to ask for a Local Government Board inquiry into the whole of the circumstances; and it may be hoped that a wholesome effect will be produced by the thoroughness with which the matter will be threshed out, not alone in the immediate district concerned, but wherever there may be any occasion to suppose that improvement in administration would tend to greater advantages.

"Penny-in-the-slot" Eyeglasses.

The craze for automatic machines shows no sign of abatement, and every now and then one is greeted with some novel application of the "penny-in-the-slot" principle. To the scientific observer there is no more curious machine than that which professes to test the sight automatically. That it is possible to roughly approximate the degree of hypermetropia or of myopia may perhaps be admitted, but it is decidedly open to question whether the adjustment of lenses should be settled by anything but accuracy. It is generally held by ophthalmic surgeons that the reading of the test types constitutes nothing more than a rough and ready method of testing errors of refraction. Nothing short of the ophthalmic mirror by a skilled retinoscopist can determine with exactitude either simple or compound ocular variations from the normal. If these propositions be established, then the use of a simply mechanical means of testing the sight will obviously be fallacious. Yet a well-known automatic sight-testing company has lately circularised the ophthalmic surgeons, inviting their co-operation and patronage. Scientific men, for the reasons above stated, cannot be expected to sanction any such claims on behalf of a business corporation. The correction of errors of refraction, we repeat, is a hightly skilled and difficult technical process, requiring not only special individual aptitude, but long practice for its acquisition. The attempt to substitute a machine worked by a penny-in-the-slot runs counter to modern ophthalmic teaching, and reduces the whole matter to the level of an absurdity.

The Irish Poor-law Superannuation Bill.

The completed memorials with reference to this Bill, which have been organised by the Irish Medical Association, to be presented by their medical constituents to all Irish Members of Parliament will go out to the local organisers throughout Ireland in the course of the ensuing week. Let us hope that not a moment will be lost in presenting them, in a proper influential way, to the M.P.'s concerned. If as much time is spent in doing this as has gone to waste in the Herculean task of dragging signatures out of the Poor-law Medical Officers (whose special interest it is to work this movement) we apprehend that the medical influence of Ireland will begin to take effect about next year. Two and three letters have been, in some cases, required to be addressed by the Association to local organisers before an answer could be got out of them, and many hundreds of reminders have been sent out to the Poor-law Medical Officers who have not even thought it worth their while to scratch their sign manual on a slip of paper and send it for attachment to the memorial. In some cases the County Councillors themselves, to whom was entrusted the duty of working up the movement in their own districts, would not take the trouble of answering a letter, and it has been necessary to take the matter out of their hands and to ask an outsider to do the work. The less we say in public about this sort of thing the better for the cause, but it will be readily understood that these facts are very disheartening to those who are, shall we say, wasting their time for the advantage of people who seem incapable of any effort save illimitable grumbling.

The International Congress at Rome.

By the time the Medical Press is in the hands of its readers, members of the Congress who intend taking part in this gathering will have arrived in the "eternal city" from all parts of the world. To-day (Wednesday) a formal reception of members will be held in the Exhibition Palace. To-morrow the inauguration will take place in the presence of the King and Queen of Italy. Upwards of 7,000 applications to attend the Congress have been received, which already exceed those of the last Congress, which was held at Berlin. Our Special Correspondent will furnish us next week with such details as will, we hope, interest readers unable to be present. We have also promises of several important papers to be read in the Sections, which will appear in our columns in due course. Meanwhile, a brief note informs us that among the distinguished personages who have already arrived in Rome are Sir Spencer Wells, Sir William Stokes, Professor A. Simpson and Professor M. Foster, who will represent Great Britain officially. Virchow, of Berlin, arrived on Saturday, and was made the object of the most cordial respect when he presented himself at the Bureau of the Medical Congress, where a number of Italian and foreign doctors were assembled. Two Japanese physicians arrived on Saturday.

Medical Etiquette in the Isle of Thanet.

By a mere chance a strange advertisement has fallen under our notice. It is on a baker's paper flour-bag, and runs as follows:—

> "Montague House,
> East Cliffe, Ramsgate.
>
> Dear Sir,—I am obliged for the sample of triticumina bread (an old friend of mine), which I shall have much pleasure in recommending; it is most palatable, nutritious, especially suited for many invalids.
>
> Yours truly,
> Channing Pearce, M.D.
>
> BRYANT & CO.
> Dinners from 1s.; teas from 6d."

We are of opinion that as a specimen of English composition the advertisement is scarcely worthy of an "M.D.," but we would like to know if the "puff" is for the baker or the doctor. We would like to know, moreover, what the profession at large in Ramsgate think of this new departure. So far as the maker of the "puff" is concerned, we would venture to ask two questions:—1st. Why did he stoop to write a trade testimonial? 2nd. And if not with a view to publication on the baker's bag (or barrow), why did he sign "M.D." after his name? We notice that on the same side of the flour-bag is the following legend:—"Families waited on; schools and large consumers liberally served." Does this refer to the baker or the doctor?

An eminent surgeon passed away on Easter Sunday in the person of Prof. Henry Smith, F.R.C.S. Deceased had been connected with King's College, and King's College Hospital, London, for the best part of half a century, and at the time of his death held the posts of Emeritus Professor of Surgery and Consulting Surgeon to those institutions. He had also received the honorary distinctions of the Presidency of the Medical Society of London, Lettsomian Lecturer and Orator; whilst his essays and papers on surgical subjects were much read and appreciated. Deceased had reached the age of seventy.

The Governors of the Irish Catholic University Medical School met the week before last and appointed Mr. M'Ardle, of St. Vincent's Hospital, to be Assistant to the Professor of Surgery, Mr. Hayes. It is understood that he will have special charge of the operative part of the teaching. Mr. Fagan and Mr. Dempsey were also appointed Demonstrators of Anatomy.

Dr. Woods, of the Richmond Hospital, Dublin, has announced a course of Post-Graduate Lectures in Electricity as applied to Medicine and Surgery, to be given in the hospital on Wednesdays and Saturdays during the summer session. Dr. Woods holds a First Gold Medal in Experimental Physics from the University.

Dr. Reginald Dudfield, M.A., M.B., Trinity College, Cambridge, D.P.H., Medical Officer of Health for the Borough of Eastbourne, has been appointed Medical Officer of Health for the Borough of Paddington, in the room of Dr. Stevenson, resigned.

We understand that Mr. Hy. Harden, whose philanthropy is well known, has given to the authorities of the Dental Hospital of London a special donation of £500 towards the sum required for the rebuilding of the Hospital, to which we referred last week.

The Annual General Congress of the British Dental Association will be held in the College of Medicine, Newcastle-on-Tyne, to-morrow and two following days. The President-elect is Mr. Chas. S. Tomes, M.R.C.S., F.R.S.

The Royal College of Physicians of London has decided upon a portrait of its late distinguished President, Sir Andrew Clark, and Mr. Lehmann has been commissioned to paint the same.

The late Dr. Roderick MacDonald has left upwards of £18,000 in the hands of trustees for the benefit of six London Hospitals. The deceased's estate amounted in all to about £28,000.

Dr. Ed. F. Trevelyan, B.Sc. and M.D.Lond., has been appointed Professor of Pathology in the Medical Department of the Yorkshire College of Medicine.

Dr. Russell Reynolds was last week unanimously re-elected President of the Royal College of Physicians of London.

Dr. Byrne Power has been reappointed Medical Officer of Health for Kingstown until the last day of December next.

Dr. E. Symes Thompson will commence the course of Gresham Lectures on April 3rd at 6 p.m., the subject being "Nerve Disorders."

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Medical Practitioner of the Future.—In concluding the winter course of lectures on Physiology at Anderson's Medical College on the 22nd inst., Prof. Campbell Black in the course of his remarks said:—"By the time you are as long in the medical profession as I have been, you will doubtless witness the extinction of the 'general practitioner' and the universal reign of the specialist. I admit that in the midst of the enormous multiplicity of details in physiology, pathology, and therapeutics, specialism is to a large extent a necessity; but precocious specialism circumscribes the mental vision and narrows the understanding. What would be thought of a young gentleman admitted to the Bar to-day sitting up in the capacity of a Judge to-morrow? After a large experience of practice I can see no objection—quite the contrary—to a man limiting his time and circumscribing his attention to the class of diseases with which it has been his lot to come most in contact, and towards which from various circumstances he has, so to speak, drifted At present the Æsculapian acolyte presumes to unravel to the gazing and admiring multitude the mysteries of disease and therapeutics exclusively through the particular little orifice of which he is self-constituted guardian angel and protector."

St. Mungo's College.—The closing meeting of the Medical Faculty in St. Mungo's College took place on the 22nd inst. Mr. Hugh Brown, Chairman of the Royal Infirmary Managers, occupied the chair. After the distribution of the medals and certificates, the Chairman briefly addressed the students. The session just closed, he said, had been very satisfactory in all respects. Whereas in most medical schools the number of students during last session was smaller than formerly, in the St. Mungo's School there had been an increase, the numbers being 85 as against 75 for the former session. St. Mungo's College was a young institution, but it was a very healthy one, and he thought he was only giving expression to a reasonable expectation when he said that the day was not far distant when it would occupy a much more prominent position as a medical school than it did at the present time. He did not know that it would ever occupy a better position as far as the teaching staff went. He regretted, and the regret too of the managers and patrons of St. Mungo's College was that so much time and so much ability was so ill-requited, so far as the pecuniary aspect of the condition of the teaching staff was concerned. The managers hoped that before very long that state of matters would be rectified, and he hoped the public would see the necessity of acting in a just way to the institution. The St. Mungo's College had many advantages to offer to her students, who reaped the benefit of its connection with the greatest infirmary but one in Scotland, and he also hoped that the students would continue to increase in future sessions as in the session just closed.

Munificent Bequest to Glasgow Technical College.—Some time ago the Governors of the Glasgow and West of Scotland Technical College made application to the Bellahouston Bequest Trustees for a grant of £125,000. Their request has just been met with the gift of upwards of £20,000, although the exact sum is not yet officially revealed. This magnificent bequest will be as cordially welcomed as it has been earnestly required.

Alleged Negligence by a Doctor.—Dr. C. J. Allan, of Lasswade, was last week mulcted of £50 at a jury trial because of alleged negligence or unskilfulness on his part in his attendance upon a labourer for a broken leg. Dr. Allan asserted that he attended the pursuer gratuitously in an emergency, that his advice was not followed, and that he understood the pursuer had become an infirmary patient. The jury unanimously awarded the pursuer £50 out of the £500 claimed.

A new Maternity Hospital in connection with the Aberdeen Dispensary was opened last week by Sir William Henderson.

An Extraordinary Tumour.—At the seventeenth annual meeting of the Glasgow Hospital for Diseases of Women, held last week, it was mentioned in the medical report that there was at that moment a patient in the hospital who had suffered from the largest tumour which had ever been successfully removed in any hospital. The tumour had been removed by Dr. Bell, and weighed more than half as much as the woman's whole body, and to-day she was perfectly well and cheerful.

WHAT CONSTITUTES UNSOUNDNESS OF MIND?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The importance of the late trial, "The Commissioners in Lunacy *v.* Sherrard," cannot, I think be overrated, and it opens up questions of the gravest importance to the public at large, as well as to the profession.

The question raised was, practically, should cases of "climateric mania" be certified as persons of "*unsound mind*," and only be admissible to an asylum or a house licensed for the reception of lunatics. Had the jury decided that such was the law, it is difficult to realise what would have been the consequences, as there are undoubtedly a large number of women suffering from this form of disease who are now treated without in any way being certified as being of unsound mind, a very large percentage of whom recover completely.

It is equally true that many women thus suffering are certified as insane and are placed in asylums. Now, had the Commissioners obtained a verdict in the above-named trial, then women must in the future, suffering from climateric mania, be certified as being of unsound mind and be branded as insane. Not only would this have affected the unfortunate women themselves, but also their families, as there would always be the stigma attaching to them that there was insanity in their family, when in reality the disease would have been purely functional and in the majority of cases curable. There is no doubt that these cases require the utmost care and attention, and during certain periods have to be attended to very closely, and here it is that the hardships of the law, as it at present stands, is most felt, for if women suffering in this way are not sufficiently well off to afford to have proper attendance at home, or to be placed into a home under the care of some medical man, then the only place available is the asylum, to gain admittance into which she must be certified as being of unsound mind. Thus there is established one law for the rich and another for the poor, which is manifestly wrong.

To remedy this state of affairs, it appears to me that there should be homes or hospitals established into which patients suffering from temporary mania might be placed for treatment without being certified, or there might be wings attached to existing asylums with the same object.

If after a given time these patients do not recover, and undoubted signs of insanity develope themselves, then, and not till then, let a certificate of unsoundness of mind be granted, and the patient removed to an asylum or a house licensed for the reception of the insane.

It would be interesting to know how many persons suffering from temporary aberration of mind, who have been placed into asylums, have actually become insane from contact with hopelessly insane people, as compared to those treated in homes, or at home under proper care and supervision, not having been in contact with actual insane people.

The importance of this subject is so vast that I trust no apology is due for bringing it under the notice of the profession with the hopes of eliciting the views of the general physician, the psychologist, and the gynæcologist.

I am, Sir, yours, &c.,

Fredk. Bowreman Jessett, F.R.C.S.

1 Buckingham Palace Mansions, S.W.

REPORT ON THE LEWISHAM LUNACY CHARGES

"Local Government Board, Whitehall,
"S.W., 20th March, 1894.

"Sir,—I am directed by the Local Government Board to state that they have had under their careful consideration the Report made by their Inspector, Dr. Downes, upon the official inquiry recently held by him with reference to the case of Joseph Mariano Williams, who was admitted into the Workhouse of the Lewisham Union in October last, together with the evidence of the several witnesses who were examined at the inquiry.

"With respect to the charge preferred against the Medical Officers of the Workhouse in connection with the removal of Williams to the Asylum, the Board are of opinion that the Medical Officers proceeded in good faith, and with due care and professional discretion, in arriving at the conclusion that Williams was of unsound mind, and had suicidal tendencies; and that, this being the case, it was their duty to take the necessary steps for his removal to the Asylum as early as possible.

"As regards the statements which have been made by Williams, the Board cannot but consider that generally they have been marked by much exaggeration, and that many of the allegations as to the incidents in the Lunatic Ward and otherwise are without adequate foundation.

"There are, however, several matters to which it is necessary that the Board should refer.

"In the first place, it appears to the Board that remarks were made in the presence of Williams, after his admission to the Workhouse, by H. Parker, the Superintendent of the Casual Wards; by W A. Cornes, the male attendant, and also by the Master of the Workhouse, which were indiscreet and improper, and the conduct of these several officers in this respect, and especially of the Master, having regard to his position at the Workhouse, is reprehensible.

"The Board also find that on the day of the admission of Williams there was a delay in his being provided with the special diet which the Medical Officer regarded as appropriate in his case, instead of the ordinary diet, and that no satisfactory explanation has been furnished of this delay. They also find that proper entries as to the case were not made in the medical relief book.

"It appears, further, that Williams was allowed to remain in the Receiving Ward until about 4.50 p.m. without the continued supervision by a paid officer, which, having regard to the conclusion arrived at by the Medical Officer as to his mental condition, it was desirable should be provided.

"As regards the Lunatic Ward in which Williams was placed, the Board direct me to state that they are satisfied that Fox was not a raving, insane man, as has been alleged, at the time when Williams was in the ward, but was already lying in a state of coma. He appears, however, to have been subject to convulsive seizures, which would doubtless cause some commotion in the ward, and it is to be regretted that the want of adequate accommodation, pending the completion of the new infirmary, rendered it necessary that Williams should be placed in the same ward as Fox.

"As regards the actual removal of Williams to the Asylum, the Board find that he was removed in a closed carriage, on a fine and fairly warm day, and that there is no ground of complaint as to the mode in which the removal was carried out.

"The Board request that their decision on the several matters referred to may be communicated by the Guardians to the Officers concerned.

"I am, Sir, your obedient servant,
"W. E. Knollys, Asst. Sec.

"H. C. Mott, Esq., Clerk to the Guardians
of the Lewisham Union."

Literature.

THE DISEASE OF INEBRIETY. (a)

This volume is really meant to be an abstract of the 5,000 odd pages of the *American Journal of Inebriety* and of the "Transactions," 1870-6, of the Association, of which the journal has been since 1877 the official organ. Dr. Crowthers (Hon. Sec.) and the Publication Committee were entrusted with the task of selection and compilation.

The book is divided into chapters arranged on the plan of Dr. Kerr's standard volume on "Inebriety," but unlike his work this before us is absolute devoid of reference to the authors from whose writings the information is drawn. This is a serious fault, full references are always of value in a debatable subject, and when the writings were gathered together in Transactions reference would have been easy. The present plan of ignoring the individual observers and merely giving a summary of ideas on each subject is unfair to the workers, and lessens the value of the present volume and of the Transactions. Of the present volume, as it represents Dr. Crowthers' view of the views set forth by others and no possibility of check is afforded; of the Transactions because full references would have made this volume a key to the Transactions and rendered them easy to study.

There is a meagre index of four pages.

Direct Alcoholic Heredity is considered common. This is a good example of the need of references to enable us to see on what grounds this assumption is built, and to see whether it is put forward in the later papers. Without accepting Weismann's theory of descent in its fullest development, there is no doubt that the present tendency is to look upon alcoholic heredity as mainly, if not altogether, indirect. A lower state of the system caused by alcoholic indulgence will cause general lowering of vitality of germ cells as well as of the structural cells, and so the offspring will be weak and inclined for nerve or other failure; the temptation to alcoholic excess being a condition of environment that is frequently the cause of failure, but this is very different from direct heredity, and much more hopeful, as changing the environment may neutralise the evil.

In addition to alcoholic inebriety, those forms caused by opium, ether, cocaine, chloroform, eau de Cologne, arsenic, and ginger are considered, as well as the effects of tea, coffee, and tobacco. In future additions references and a fuller index should be added.

RIDGE'S ALCOHOL AND PUBLIC HEALTH. (b)

This is a second edition of Dr. Ridge's handbook, which was first published in 1892. It contains in a concise form a great deal of information on the exact action of alcohol, and probably in no other book is so much told of the exact action of small doses. Dr. Ridge has tried numerous experiments; one, that of growing geraniums watered with plain water and with 1 per cent. alcohol solution, has been much criticised, but Dr. Ridge does not claim to have proved that, because alcohol injuriously affects growing plants, it must also be injurious to animals, but that the effect on plants is a strong confirmation of what is proved to be the effect on animals.

The chapter on the physiological action of alcohol is the most valuable. Dr. Ridge extended the observations of Kræpelin to all the special senses, and found in every case lessened, and not increased, power. In other words, alcohol, from the first, was narcotic and not stimulant.

The perusal of Dr. Ridge's thoughtful *brochure* will make many medical men more selective in the cases in which they prescribe alcohol.

MARTIN'S DIPHTHERIA. (a)

After a short account of diphtheria and the views concerning it held by various writers, the author divides the disease into five stages:—(1) Incubation; (2) Prior to Exudation; (3) Exudation; (4) Formation of False Membrane; (5) Convalescence or the Reverse. The second stage is known by the dusky red hue and granular surface of tonsils, pharynx, soft palate, severally or altogether. The author claims that his treatment if applied in the second stage will prevent exudation, and that in the third and fourth stages it will still cure. The internal treatment presents no new features except the wise recommendation not to fly too rapidly to brandy. Iron and chlorate of potash, or, if seen early, diaphoretics are recommended. The local treatment is what the author chiefly relies on, and what he claims as curative. It is frequent insufflations with sulphite of magnesium, this the author claims will prevent exudation, keep exudation from turning into membrane, and dissolve membrane. Five illustrative cases are given, and the author says they are only a few out of many. We hope others will find this treatment, which, at any rate, is easily tried, efficacious.

Medical News.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 33, Bombay 36, Madras 40, Paris 25, Brussels 21, Amsterdam 17, Rotterdam 23, The Hague 17, Copenhagen 20, Stockholm 15, Christiania 22, St. Petersburg 27, Moscow 32, Berlin 17, Hamburg —, Dresden —, Breslau 28, Munich 22, Vienna 31, Prague 30, Buda-Pesth 21, Trieste 40, Rome 26, Turin 27, Venice 32, Cairo 50, Alexandria 42, New York 22, Brooklyn 19, Philadelphia 22, New Orleans 24.

Vital Statistics.

The deaths registered last week in the principal large towns of the United Kingdom corresponded to an annual rate of 19·2 per 1,000 of their aggregate population, which is estimated at 10,458,442 persons in the middle of this year, and were—Birkenhead 18, Birmingham 19, Blackburn 19, Bolton 16, Bradford 18, Brighton 13, Bristol 20, Burnley 24, Cardiff 14, Croydon 12, Derby 20, Dublin 25, Edinburgh 19, Gateshead 22, Glasgow 23, Halifax 15, Huddersfield 14, Hull 18, Leeds 18, Leicester 16, Liverpool 25, London 19, Manchester 21, Newcastle-on-Tyne 12, Norwich 14, Nottingham 16, Oldham 21, Plymouth 19, Portsmouth 18, Preston 20, Salford 24, Sheffield 18, Sunderland 17, Swansea 21, West Ham 18, Wolverhampton 20. The highest annual death-rates were—From measles, 2·0 in Birkenhead; from scarlet fever, 1·6 in Burnley; from whooping-cough, 1·2 in Plymouth; from fever, 1·1 in Liverpool; and from diarrhœa, 1·1 in Derby. The 79 deaths from diphtheria included 52 in London, 6 in Glasgow, 3 in Manchester, and 2 each in Edinburgh, West Ham, Birmingham, and Sheffield. Eight deaths from small-pox were registered in Birmingham, 3 in London, 2 in Edinburgh, 2 in West Ham, and one each in Glasgow, Cardiff, and Oldham, but not one in any other of the towns.

Notices to Correspondents. Short Letters, &c.

THE OATHS ACT.

In our issue of the 7th inst. we published "The Law Regarding Oaths," at the same time offering to supply our readers with a copy for their pocket-books without charge. We beg to notify that these have now been nearly all applied for, and that a few copies only remain, for which immediate application must be made, accompanied with a halfpenny stamp to cover the postage.

Mr. Vander.—Amsterdam is not as a whole an unhealthy city. Fever is not endemic there, and the rates of mortality will compare favourably with most other large cities. Your doubts as to the correctness of the information given you are well founded.

LETTERS TO THE EDITOR.

In consequence of intervening holidays the following letters were received too late for attention in the present number:—

A Gynæcological Question Relating to the Hymen. By J. Hamilton, M.D.

A Problem: the English Death-rate from Hydrophobia. By Dubious, M.D.

Vivisection and Progress. By Ed Haughton, M.D.

The Contagious Diseases Act in India. By Ramden (Brahman).

Medical Orthoëpy. By P. Z. Herbert, M.D.

QUACK MEDICINES.

First Quack—Here is a letter it would not do for us to publish. A man writes: "I have just taken my first bottle of your medicine and I—"

Second Quack—Well?

First Quack—Then it breaks off short and is signed in another handwriting, "See executor."—*Dominion Medical.*

A Fellow.—A new edition of the work is announced as "now ready," but we understand it has not yet appeared.

A Provincial Surgeon.—1. Everything depends on the nature of the arrangement, if it were verbal it cannot be enforced, if in writing, it can. 2. We should advise you not to press this point.

Mr. Sydney Stephenson's article on the "Spread of Ophthalmia by Washing Utensils" is marked for early insertion.

Studens.—Œnanthol or œnanthyl is the hypothetical radicle of œnanthylic acid and its derivatives. We are not surprised that you should have failed to answer this question. The same name is sometimes given, but inappropriately to heptyl. The varieties are almost innumerable; the principal ones are: œnanthylic ether, chloride, hydride, acid aldehyde, and anhydride. Œnology expresses the science of that branch of wine which deals with its nature, qualities, and varieties.

THE JENNER RELICS.

To the Editor of The Medical Press and Circular.

Sir,—The collection of Jenner relics, which has been removed from the Bristol Exhibition, will be on view at the First Avenue Hotel, Holborn, London, on and after March 26th.

It is intended to offer the collection to the Royal College of Surgeons, England, and a subscription list will be placed upon the table where the collection is shown, and in which visitors are requested to write their names and subscriptions.

There are several very poor relatives of the Jenner family still living, and it is proposed to divide a portion of the subscriptions to relieve them.

I am, Sir, yours, &c.,
Frederick Mockler.

Meetings of Societies, Lectures, &c.

WEDNESDAY, MARCH 28TH.

West London Hospital (Hammersmith).—At 5 p.m., Mr. Cheatle: Bacteriology of Wounds and Antiseptics. (Post-Graduate Course.)

FRIDAY, MARCH 30TH.

Clinical Society of London.—At 8.30 p.m., Mr. Christopher Heath: Two cases of Rectangular Ankylosis of the Hip-joint treated by Operation.—Mr. G. R. Turner: A case of Aneurysm by Anastomosis.—Mr. Hurry Fenwick: Resection of Part of the Left Lower Lateral Wall of the Bladder for Recurrent Epithelioma.—Mr. Battle: A case of Traumatic Rupture of the Bile Duct.—Mr. Arbuthnot Lane: Large Stones in the Common Bile Duct producing Complete Obstruction; Fæcal Material in the Duct; Operation; Recovery.

MONDAY, APRIL 2ND.

Odontological Society of Great Britain.—Adjourned Discussion on Root-Filling.

THURSDAY, APRIL 5TH.

Harveian Society.—At 8.30 p.m., Clinical Evening.

Vacancies.

Bedford General Infirmary and Fever Hospital.—House Surgeon. Salary £100 per annum, with apartments, board, lodging and washing. Applications and testimonials to the Secretary on or before April 10th.

Carnarvonshire and Anglesey Infirmary.—House Surgeon. Salary £70 per annum, with board and lodging. Applications and testimonials to the Secretary on or before April 7th

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary 100 guineas per annum. Applications and testimonials to the Secretary on or before April 12th.

Leith Hospital.—House Physician, House Surgeon, and Surgeon. Salary £50 per annum each. Applications and testimonials to the Secretary on or before April 4th.

Morpeth Dispensary.—House Surgeon. Salary £120 per annum, with furnished house, &c. Applications and testimonials to the Hon. Secretary on or before April 4th.

National Hospital for the Paralysed and Epileptic (Albany Memorial), Queen Square, Bloomsbury.—House Physician. Salary £100 per annum, with board and apartments. Applications and testimonials to the Secretary on or before March 31st.

Royal Hants County Hospital, Winchester.—House Surgeon. Salary £100 per annum, with board and lodging. Applications and testimonials to the Secretary on or before April 11th.

Sheffield School of Medicine.—Tutor. Salary £125 per annum. Applications to the Secretary on or before April 2nd.

University College, Bristol.—Medical Tutor. Salary £125 per annum. Applications and testimonials to the Dean on or before April 4th.

Warminster Local Board.—Medical Officer. Salary 30 guineas per annum. Applications and testimonials to the Clerk on or before March 31st.

Appointments

Baine, L. A., M.D., B.S.Durh., D.P.H., Assistant Medical Officer to the Monsall Fever Hospital, Manchester.

Dalby, J. L., M.R.C.S., L.R.C.P., Senior House Surgeon to the East Suffolk Hospital.

Davies, R. T. E., L.R.C.P., L.M.Ed., M.R.C.S., Medical Officer for the New Tredegar Sanitary District of the Bedwellty Union.

Dempsey, M. S. P., M.D., B.Ch.Dub., Demonstrator of Anatomy to the Catholic University School of Medicine, Dublin.

Fagan, P. J., L.R.C.P., L.M., L.R.C.S.I., Demonstrator of Anatomy to the Catholic University School of Medicine. Dublin.

Hammond, W., L.R.C.P., L.M.Ed., M.R.C.S., Medical Officer of Health for the Sixth Sanitary District of the Liskeard Union.

McArdle, J. S., L.R.C.P., L.M., F.R.C.S., Assistant to Professor of Operative Surgery, Catholic University School of Medicine, Dublin.

Murphy, D., M.B., B.Ch., Resident Physician to the Cork Fever Hospital.

Power, S. B., M.R.C.P., L.M., L.R.C.S.I., Port Medical Officer for Kingsdown.

Purvis, W. P., L.R.C.P.Lond., B.Sc., M.R.C.S., House Surgeon to the Royal South Hants Infirmary.

Smith, F. P., L.R.C.S.I. & P.I., House Surgeon to the National Eye and Ear Infirmary, Dublin.

Star, P., M.R.C.S.Eng., L.R.C.P.Lond., Senior House Surgeon to the Clayton Hospital and Wakefield General Dispensary.

Stephen, J., M.D., C.M.Aberd., Deputy Medical Officer for the Burgh of Peterhead.

Waddy, F. H., M.B., C.M.Glasg., Non-resident House Surgeon to the Brighton, Hove, and Sussex Throat and Ear Hospital.

Ware, H. S., B.A., M.B., B.S.Camb., Resident Medical Officer to the City of London Hospital for Diseases of the Chest.

Westmacott, F. H., L.R.C.P.Lond., M.R.C.S., Resident Medical Officer to the Barnes Convalescent Home of the Manchester Royal Infirmary.

Williams, A. F., L.R.C.P.Lond., M.R.C.S., District Medical Officer and Public Vaccinator for the Parish of Wandsworth.

Births.

Barnardo.—March 25th, at Ardmore, Buckhurst Hill, the wife of Thos. J. Barnardo, F.R.C.S.E., of a daughter.

Benson.—March 18th, at Grosmont, Pontsilas, R.S.O., the wife H. P. D'Arcy Benson, M.B., Ch.M.Edin., of a son.

Cadell.—March 18th, at Clare House, Tiverton, the wife of Nevil P. Cadell, L.R.C.P., &c., of a son.

Ferguson.—March 17th, at 25 Rutland Street, Edinburgh, the wife of James Haig Ferguson, M.D., F.R.C.P.E., of a daughter.

Hopkins.—March 19th, at 5 Picton Place, Swansea, the wife of G. Herbert Hopkins, F.R.C.S.Eng., &c., of a son.

Mackay.—March 23rd, at 7 Hallgate, Doncaster, the wife of P. R. Mackay, M.R.C.S., L.R.C.P., of a son.

Pincott.—March 22nd, at 1 Calverley Parade, Tunbridge Wells, the wife of J. C. Pincott, M.R.C.S.E., L.R.C.P., of a daughter.

Price.—March 22nd, at Park View, Carshalton, Surrey, the wife of Arthur G. Price, B.A., M.B., of a son.

Marriages.

Adam—Ness.—March 20th, at St. John's Wood Presbyterian Church, John Adam, M.D., eldest son of Æneas Adam, J.P., Humberston, Ross-shire, to Annie, the fourth daughter of the late James S. Ness, J.P., of London.

McKenna—O'Neill.—At St. Joseph's, Carrickmacross, by the Very Rev. Dean Birmingham, D.D.P.P., Vicar Capitular, P. McKenna, M.B., M.Ch., R.U.I., &c., to Maggie, daughter of the late James O'Neill, Esq., Carrickmacross.

Deaths.

Clarke.—March 20th, at Fairy Cottage, Rostell, Yorks., William Barnard Clarke, M.D., formerly of Ipswich, aged 87.

Macfarlane.—March 17th, at 73 Tollington Park, London, N., William Macfarlane, M.D., aged 65.

Richards.—March 15th, at 361 Moseley Road, Birmingham, from acute pneumonia, William Richards, M.D.Edin., aged [illegible].

Smith.—On Easter-day, at Horsell, Henry Smith, F.R.C.S., of Wimpole Street, London, Emeritus Professor of Surgery at King's College, and Consulting Surgeon to King's College Hospital, aged 70.

Webb.—March 14th, of typhoid fever, at Nesham House, Houghton-le-Spring, Durham, John A. Webb, L.R.C.S.E., L.A.H.Dub., and L.M., late of Blackrock.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

Original Communications.

OVARIOTOMY
PERFORMED ON AN INSANE PATIENT EXEMPLIFYING ALSO THE LIFE HISTORY OF AN UTERINE FIBROID. (a)

By LOMBE ATTHILL, M.D.,

Ex-Master of the Rotunda Hospital, Dublin.

ALTHOUGH we frequently have patients under observation for years, in whom the uterus is the seat of a fibrous tumour, it is seldom that an opportunity is afforded of watching its development from almost its earlier stage, till it attains its maximum size, during which we have to combat the various distressing, and indeed, often dangerous symptoms it gives rise to, then to witness the retrograde metamorphosis which generally commences after the climacteric period is reached, and finally, to verify the fact that the tumour has disappeared, and that the uterus has been restored to almost its normal state. It is mainly because it has fallen to my lot to witness all these phenomena that I bring forward the following case:—

A lady, married some fifteen years and then æt. about 37, came under my care in 1882. She had never been pregnant and had enjoyed good health till about two years previously, when having gone through a period of great mental anxiety, she began to suffer from slight attacks of hæmorrhage which came on whenever anything occurred to worry or excite her, these sometimes were profuse, probably marking the menstrual periods, but of this she could not be sure as they recurred irregularly.

On examining her I found the fundus to be enlarged and retroflected, while a small polypus projected from the os uteri. The diagnosis I made at the time was "cervical polypus and probable uterine fibroid." I removed the little polypus and put her on ergot but no benefit resulted, and the hæmorrhages became even more profuse. I therefore dilated the cervix but there was no intra-uterine growth, so I curretted and applied nitric acid freely and subsequently injected iodised phenol into the cavity. The result of this treatment was that the irregular hæmorrhages ceased, but menstruation recurred too soon and was very profuse and weakening.

For the nine following years I saw this lady frequently. The uterus steadily increased in size and became nodulated, thus confirming the original diagnosis that its wall was the seat of a fibroid. Finally it attained the size of the fœtal head at full term, the fundus reaching nearly to the umbilicus, and friends supposed from her figure that she was pregnant, then she became insane and was admitted into an asylum and I lost sight of her.

More than once I had suggested operative interference, for the hæmorrhages were sometimes alarming, but the suggestion would not be listened to. A few weeks ago I was requested to visit this lady in the asylum, the reason being that the abdomen had recently increased rapidly in size, though she herself had become extremely thin. I should say that since she became insane great difficulty had been experienced in getting her to take food.

On visiting her I was told that she had ceased to menstruate soon after her admission into the asylum. The abdomen was occupied by a large fluctuating cyst, the fibroid which used to be so prominent could not now be felt, and the only question was whether a cyst had been developed in the fibrous tumour whose growth I had so long watched, or was it a recently developed ovarian one. I believed it to be ovarian but the patient resisted so vigorously that unless under the influence of an anæsthetic anything like a satisfactory examination was impossible.

The attendants were so clear, judging from her size, that the tumour was increasing rapidly that I advised that she should be ready for the performance of an abdominal section if when in an insensible state, that seemed advisable, that point to be decided at the time. The patient's mental condition was such that I considered the administration of an anæsthetic should, if possible, be avoided.

Her friends agreeing to my suggestions she was brought under the influence of chloroform without trouble, and then the existence of a large ovarian cyst was verified, but no trace of the fibroid could be made out. Ovariotomy was rapidly and easily performed, there were a few adhesions anteriorly, the pedicle was long and easily secured and the tumour was removed. Then we proceeded to examine the state of the uterus, it was but little larger than it should have been in a woman of her age (49) and no trace of the nodulated tumour so easily traced three years before could be felt. The rapid atrophy of this tumour was most probably accelerated by and no doubt in part the result of the insufficient quantity of food she had consumed since she became insane. As already observed there had been a constant difficulty in getting her to take food and the one great complaint she made to me was that "they were always forcing her to swallow food," this fact confirms the truth of a rule I have always laid down in the treatment of bleeding fibroids, namely that it is unwise for such patients to take large quantities of nutritious foods. If you feed highly more blood will be manufactured, the more rapidly will the tumour grow and the greater will be the loss of blood, specially during the menstrual periods. Moderate unstimulating diet and abstinence from spirits, wines, porter, &c., should in general be the rule in such cases.

This patient made a rapid recovery and though very restless even to the extent of sitting up in the bed frequently during the very day on which the operation had been performed she had no bad symptom. Her friends hope the operation may result in the improvement of her mental condition, but I fear that these hopes may not be realised, her general health certainly is, at the end of only a few weeks decidedly better, and she takes food comparatively freely now.

(a) Read before the Obstetrical Section of the Royal Academy of Medicine, Ireland.

OVARIOTOMY,

FOLLOWED BY MELANCHOLIA.

By Wm. HORROCKS, M.B., F.R.C.S.,
Surgeon to the Bradford Infirmary.

A. B—, an unmarried weaver, æt. 35, was admitted to the Braford Infirmary on April 30th, 1892, complaining of abdominal pain. Two years before, she had a sudden attack of severe pain in the lower part of the abdomen on the right side. During this illness, which lasted about a week, there was no vomiting or stoppage of the bowels. Since this time patient has never been quite free from abdominal pain. Five months ago she had retention of urine, and was catheterised daily for a fortnight. At this time she vomited, had acute abdominal pain with obstruction of the bowels for several days. Catamenial discharge was natural until recently, when there has been pain at periods with diminished loss of blood. Patient is a sullen-looking woman, who answers questions reluctantly. Examination of lungs and heart showed no abnormality. Urine is healthy. The abdomen is full, especially at the lower part. Between the umbilicus and pubes is a fluctuant swelling with rounded, regular outline. The vagina is narrow with a pointed cervix uteri pushed up behind the pubes to the left of the middle line. The sound passes 3½in. upwards and to the left. Occupying Douglas' pouch and the right broad ligament is a defined fluctuant swelling, which reaches down nearly to the cervix. The mucous membrane of vagina is not adherent. Tumour seems to rise out of the pelvis on pressing from below.

On May 10th, patient being etherised, a median incision 3½ inches long was made below the umbilicus. The bladder wall was seen at the lower part of the incision, and was drawn downwards without difficulty. The anterior wall of the tumour, crossed obliquely by the flattened right Fallopian tube, was now exposed. About a pint of thick, greenish fluid was evacuated, and an ineffectual attempt made to draw out the tumour, which had grown between the layers of the broad ligament. Growing on the anterior surface was a second pedunculated tumour about the size of a tangerine orange. It ruptured during the operation, its watery contents escaping into the abdomen. The anterior peritoneal covering of the larger tumour was incised and the cyst shelled out with difficulty until a pedicle was formed and tied. The tumour was removed and the peritoneal sac stitched with continuous catgut suture. A glass drain was inserted with its lower end touching the floor of Douglas' pouch. The abdominal wall was closed by three sets of sutures. The removed tumour showed the Fallopian tube extending over its anterior surface. Its wall showed at one part the remains of the flattened and atrophied ovary, showing that the tumour was ovarian in origin, but had grown between the layers of the broad ligament. The collapsed pedunculated cyst was parovarian.

The wound healed without complication. On the evening after the operation the patient got out of bed and walked to the door of the ward. On the following days she sobbed, and cried frequently. She said, that she was a cat and heard noises which the nurse did not hear. On one occasion she attempted to go home.

Dr. Major kindly saw her on June 1st. He considered it a case of melancholia with delusions, associated with hallucinations of hearing certainly, perhaps also of sight.

June 3rd.—Patient continues in the same mental condition. Had retention of urine for fourteen hours. She returned home after the wound healed but continued in a depressed mental state with delusions for several months. She gradually recovered from her depression so that she is now at work. There is no insanity, at least none requiring professional care, in the family.

Melancholia after ovariotomy is so unusual that the case is worthy of record. Dr. Major suggested the anæsthetic (ether) as the cause, but my own impression is that it was caused by depression and fear of the operation. I learnt afterwards that she had not slept for several nights before the operation.

◆

THE
PLACENTA IN ECTOPIC GESTATION
AND
ITS GROWTH AFTER THE DEATH OF THE FŒTUS.

By ALFRED S. GUBB, M.D. Paris, &c.

(*Continued from page* 331.)

It would be easy to multiply instances in which cases of undoubted ectopic gestation have yielded on operation, more or less voluminous masses of placenta with a disproportionate fœtus or no fœtus at all. I will content myself with two or three selected from the note books of Mr. Lawson Tait by his kind permission, the anatomical specimens from which I have been enabled to examine in the museum of Queen's College, Birmingham.

In Case 6 the rupture had occurred apparently after the tenth week of gestation, and the placenta was lying in the midst of a quantity of clots as a rounded mass, the size of a cricket ball, for the most part in the wall of the tube for when the tumour was removed the placenta was still adherent of its inner surface, and the pelvic mass was intact. On slitting it open the ovum cavity was found to contain about a dessert-spoonful of liquor amnii, but there was no trace of a fœtus at all.

In Case 19 when the fœtus was found it was only about 2½ inches long, and it had evidently been dead for some considerable time, for it was partly digested, whereas the placenta had grown to be quite as large as that of an intra-uterine placenta of four or five months, and it had contracted adhesions to intestine, and omentum, giving rise to recurrent hæmorrhages for which the operation had ultimately to be performed. Similar appearances occured in Cases 24, 30, 32, and 27. Mr. Tait indeed observes: "In looking over the records of cases which have gone beyond the full period of gestation, I find numerous illustrations which can not be other than the growth of the placenta after the death of the child. No emphasis is in any case laid upon this fact, but the descriptions completely establish it." Another point in which Mr. Tait was greatly interested was that indicated by Mr. Knowsley Thornton when he gave evidence that the placenta grew after the death of the fœtus. When evidence on this point was first brought forward it was, he says, one of the observations to which he had listened with the greatest hesitation, but he held that there is now no question that it was so and that it occurred in a fairly large number of the cases.

It is stated (Kustner, "Handbuch des Geburtshilfe,") that the placenta in tubal pregnancy presents a very elementary construction and differs from the organ developed *in utero*, by less intermingling of the fœtal and maternal tissues and by the absence of intervillous blood spaces. This description does not always hold good, for several preparations in my possession show lacunæ to be present. The supposed rudimentary condition of the placental tissues connecting mother and child in tubal pregnancy is difficult to reconcile with the fact that a fœtus can be fully developed outside the uterus.

The frequency with which the placenta attains a size altogether out of proportion of the fœtus proves beyond a doubt that it undergoes enlargement, at any rate, after the death of the fœtus, though I must admit that it is often difficult to make out with the naked eye, or even with the microscope, what particular elements of the placenta contribute to this increase of size. What usually occurs is congestion with sanguineous exudation filling up the interstices and converting a spongy mass into one of liver-like consistency. Moreover, the apparent bulk may be considerably added to by firmly coagulated blood clot. In such cases one sees the lacunæ filled with solid coagulated fibrinous mass, the villi having undergone hyaline degeneration, some quite structureless and only recognisable by their outline, so as to appear in the microscopical preparations as irregular hæmatoxylin stains.

The development of the placenta in cases of tubal pregnancy differ in several points from that observed within the uterus.

Microscopic appearances suggest that though the fœtal parts of the placenta do not undergo development in the physiological sense of the term they proliferate and develope a large quantity of lowly organised connective tissue within which the normal placental elements are strangled, so to speak. Certain it is that in most instances it is by no means easy to demonstrate the placental structure, though with patience the presence of a few scattered and atrophied villi usually furnishes the necessary evidence.

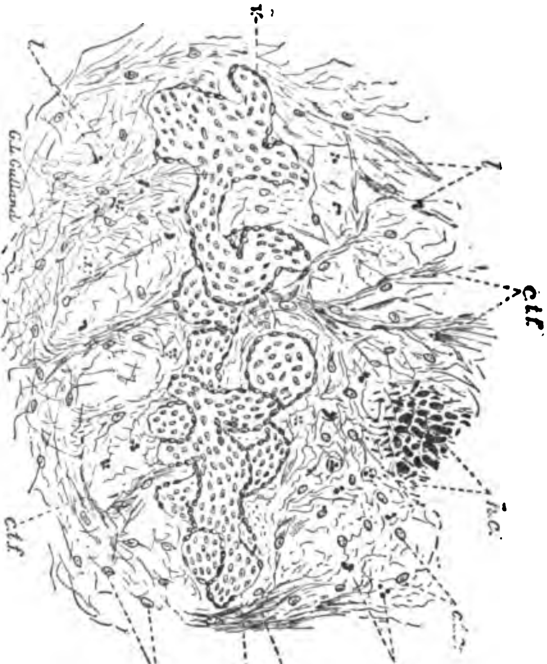
In a paper on the subject from the pen of Dr. Berry Hart, of Edinburgh, this very painstaking observer controverts a conclusion admitted by him to have been arrived at "by several observers well qualified to judge" as to the growth of the placenta after the death of the fœtus. For this statement, he says, there appears to be no adequate basis. Before one could make such a deduction it must be shown—(1) that the placenta in cases in which the fœtus is alive is distinctly smaller than in those where some time previous to examination the fœtus has died; (2) the part that so grows should be demonstrated by an examination of such cases as are indicated under (1). Such proof he observes has not been given.

Dr. Berry Hart has had an opportunity of personally examining post-mortem four cases of extra-uterine gestation in regard to this alleged growth of the placenta after the death of the fœtus. One of these was a broad ligament gestation, the others were advanced abdominal gestations. All were examined by means of frozen sections and microscopic examination of the placentæ were also made. These cases are now to be considered :—

Broad Ligament Gestation.—This was a pregnancy which had developed between the layers of the broad ligament, and was at about 4½ months. The fœtus lay below while the placenta was at the roof of the sac. This paper is figured in the original paper by Mr. Carter and himself, and copied in Mr. Tait's "Ectopic Gestation" and Bland Sutton's last work. The fœtus was quite fresh and not macerated, and seemed less advanced than one would have expected. The placenta formed a firm mass attached to the extra-uterine peritoneal surface of the top of the broad ligament, and measured 2¾ inches vertical measurement and 2 in. in breadth.

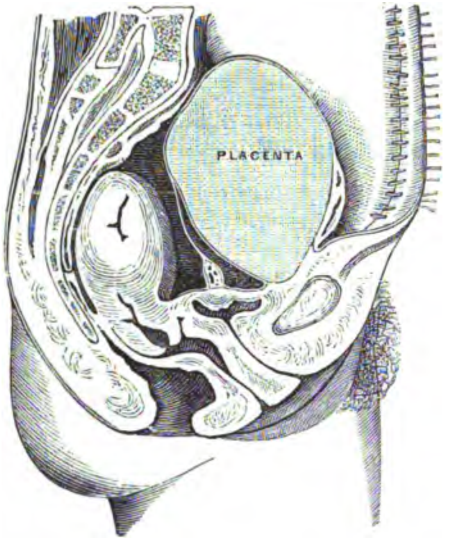
On microscopical examination it was found to be made up of villi which in structure and arrangement differed considerably from the normal. They were disposed very irregularly, and were not nearly so numerous as in ordinary placenta. The individual villi were compressed so that the connective tissue of which they were formed was much denser than usual and their nuclei very much crowded together. Here and there were vessels to be seen in the villi. A covering of a single layer of flattened epithelium could usually be traced around them but sometimes this seemed to have disappeared. These villi were imbedded, not in blood spaces as in the normal placenta, but in connective tissue of the ordinary areolar variety in which were a certain number of fat cells here and there traversed by unstriped muscular fibres.

This connective tissue was sometimes compressed in the neighbourhood of the villi, and in the same situation its meshes were often full of leucocytes. The blood vessels of this connective tissue were fairly numerous but stood in traceable relation to the villi. But the most striking feature in the sections was the enormous number of hæmatoidin crystals scattered through them. These were evidently the result of old blood extravasations, and these had apparently occurred at different dates judging from their disposition. There were brown masses as large as peas in the preparations entirely made up of crystals large and small, while all through the connective, but especially close to the villi were smaller foci in which the crystals are usually small. All trace of red blood corpuscles had disappeared from these masses but many leucocytes were to be found in the smaller ones and at the margins of the larger masses where there also was a certain amount of newly formed connective tissue. These extravasations had in many instances displaced the connective tissue considerably from around the villi, and compressed villi were here and there to be seen in the midst of the larger masses of crystals.



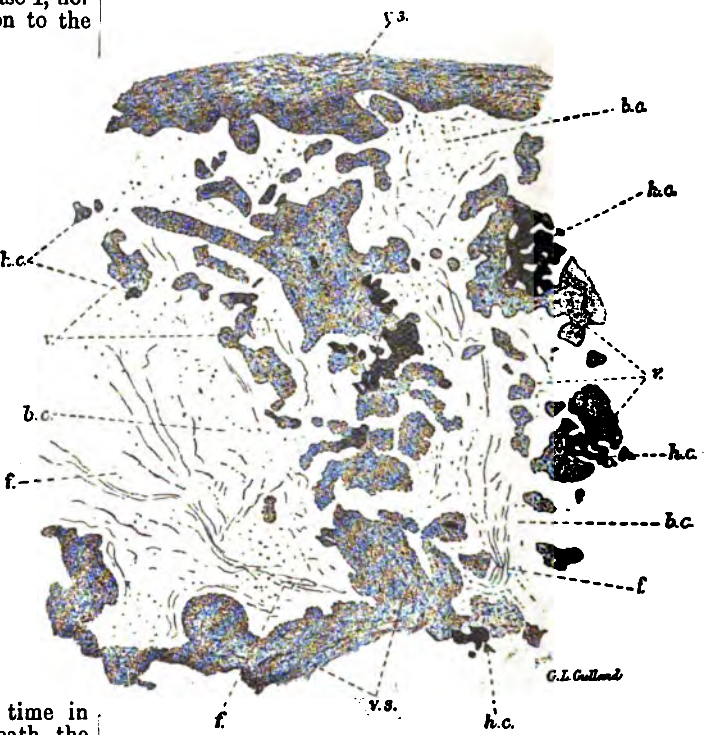
5.—Extra-uterine placenta at term × 250. V. Chorionic villi. H. C. Hæmatoidin crystals. C. T. C. Connecting tissue cells. L. Leucocytes. C. T. F. Connective Tissue.

II.—Case of advanced extra-peritoneal gestation, (*vide* Hart and Carter, *Edin. Med. Journ.*, vol. 33, page 332.) Here the woman was supposed to have gone beyond the time of normal pregnancy. The fœtus had begun to decompose, but was fairly nourished and not macerated. It weighed two pounds four ounces. The placenta was attached to the anterior abdominal wall and inner surface of the peritoneum as follows:—It measured 5 2/5 inches vertical, 3¾ inches from side to side, and 3¼ antero-posterior (13½ cm. by 8 cm.) and was somewhat cocoa-nut-shaped. To the naked eye and to the touch it had a firm spirit-hardened, liver-like aspect and feel. On microscopical examination it was found practically to consist of connective tissue with large areas of extravasated blood crystals and tortuous villi with more or less degenerated epithelium. More particularly it may be described as follows:—In this case the placenta is formed almost entirely of the fœtal villi and blood clots more or less organised, the maternal connective tissue takes but little or no part in its structure. The villi, though somewhat altered, are not nearly so compressed as those in Case I, and the alteration in them consists rather in an extreme tortuosity and distortion of the villi as a whole, than in any very marked pathological change in its individual elements. The villous stems are generally isolated and often widely separated from each other. They are embedded in connective tissue of a very low type apparently the result of the organisation of blood clot, as numerous masses of hæmatoidin crystals are found scattered through it. Some of the crystals are very large, others very small, but the organisation of the extravasations has gone on to greater perfection. Many capillaries are to be found in the more fully organised parts of the intervillous tissue, few in the less perfectly organised areas. Leucocytes are numerous, but they have not the same marked relation to the villi as in Case I, nor are the capillaries arranged with any relation to the villi.



6.—Vertical (frozen) section of a woman, the subject of an ectopic gestation, showing the enormous placenta. (Berry Hart.)

III.—Abdominal gestation, fœtus at full time in peritoneal cavity with placenta lying beneath the pelvic peritoneum, and in part above the bladder. This specimen has not been especially described before. Abdominal section was performed by Prof. Simpson, and a dead fœtus extracted. On post-mortem the pelvis was removed by Dr. Barbour. The points of interest in the clinical history are as follows:—Last menstruation at beginning of July, 1886, severe vomiting in September with bloody discharge and apparent abortion (evidently a decidua), then a great deal of pain persisting for weeks, beginning usually at 10 p.m. and lasting till 4 or 5 a.m. In the beginning of April fœtal movements ceased, pain passed off, and the abdomen diminished in size. On physical examination a tumour was felt reaching from the pelvis and the right iliac fossa to below the left ribs. Vertical measurement, eight inches. The head of the fœtus could be felt between the examining hands immediately the ribs on the left side. The fœtal limbs lay to the front and to the right, and are felt distinctly. No bruit or fœtal heart sounds. On vaginal examination the os admitted the tip of the finger. Rest of examination unsatisfactory, but a round elastic swelling is felt through the roof of the vagina (placenta?). She was seen at intervals by three specialists. Symptoms of peritonitis and obstruction of the bowels came on after dilatation of the cervix by tents, and on May 22nd Prof. Simpson performed laparotomy and extracted the child, now dead, from the amniotic cavity lying intra-peritoneally. The cord was found separated about two inches from the navel. The placenta which lay below was not touched. The patient died on May 24th, 1887. The child weighed five pounds and measured twenty inches, the skin peeling and the bones of head soft. It was fully developed and had no external malformation except right talipes varus. When the pelvis was removed it was frozen and sawn in sagittal mesial section. The uterus lay retroposed and the placenta extra-peritoneal, placed beneath the pelvic peritoneum and in the middle line above the bladder. It was a rounded mass measuring four inches in all its diameters. It has the ordinary liver-like aspect, and is firm to the touch. Large veins are seen lying at its anterior and posterior edges.

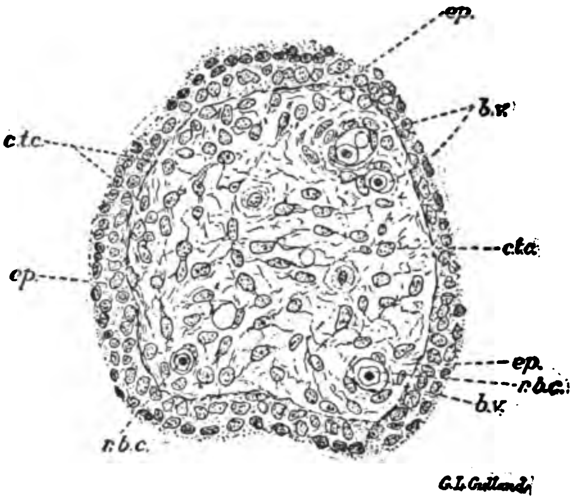


7.—Extra-uterine placenta at term × 50. v. s. Chorionic villi. h. c. Hæmatoidin crystals. f. Fibrin. (Berry Hart.)

The placenta on microscopical examination presents a much more nearly normal appearance than in either of the foregoing cases. In some places the villi are as closely packed together as in the normal placenta, and they are in most situations identical with normal villi, but here and there are widely separated from each other. In this placenta blood extravasations have occurred, the villi are embedded not in connective tissue, but in blood clot. In this the outlines of the red blood corpuscles are still recognisable in places, though there are many threads running through it, and in some places, especially round some of the villi, dense layers have been deposited. There are many hæmatoidin crystals also of large size and found almost exclusively near the villi. There is little or no maternal connective tissue except near the margin of the placenta, and in the specimens examined the blood clot had nowhere as yet become organised.

IV.—Case of full-time intra-peritoneal extra-uterine pregnancy, placenta in tube, fœtus and amniotic sac in peritoneal cavity. Laparotomy by Dr. Halliday Croom and dead child extracted; mother died. The chief facts regarding the nature of the placental sac are as follows :—(1) Increase in size of Fallopian tube accompanying growth of the placenta due to increase in both connective tissue and in muscle, but chiefly in the former. (2) The proportion of these elements to each other is the reverse of what is found in the normal tube, the connective tissue being greatly in excess. (3) The connective tissue is very compact for the most part. (4) The normal arrangement in two layers is completely altered, the fibres being found in groups which run in various directions. (5) There is enormous enlargement of vessels opposite the placental site, and the large sinuses are found chiefly in the deep layers of the wall. (6) Trabeculæ containing vessels extend into the placenta from the walls. (7) The epithelium normally lining the tube no longer exists. No glandular structure like that found in uterine pregnancy being seen. (8) No decidual cells are found anywhere in placental sac wall. (9) Placenta at the time of operation in its sac, was a discoid mass in the left side of the pelvis extending above the brim for about three inches. (10) After death (thirty-eight hours after operation) the shape being changed owing to blood extravasation into its substance, so that it was found an irregularly rounded mass, the greater portion of the placenta being destroyed. (11) Sections of the unaltered placental tissue resembled closely those of normal tissue in uterine pregnancy. (12) Villi are seen attached to sac wall. (13) Trabeculæ of various sizes pass from the sac wall into the placental substance. (14) In several places the placental structure is much altered by old hæmorrhages, the villi being compressed and having lost their covering epithelium, in some cases having a sort of hyaline degeneration, but in most cases having become very fibrous their vessels being obliterated and indicated by lines of blood crystals; blood clots are seen in various stages of degeneration. (15) The amniotic covering resembles that seen in an ordinary placenta. (16) The chorionic layer under the amnion is of dense fibrous tissue from which villous stems project. (17) Secondary (peritoneal) sac which contained the fœtus is lined throughout with amnion, which in many cases is considerably wrinkled. It consists of a layer of epithelial cells resting on a thin layer of connective tissue which is attached to a fibrous layer altered and thickened peritoneal covering of the various structures to which it was attached.

Dr. Berry Hart then proceeds to discuss what explanation can be given of the undeniably altered condition of the placenta, especially in the first three cases to which the present remarks apply. He says, "It cannot be the fœtal portion as the fœtus is alleged to be dead, and there is no special portion in advanced cases except the ordinary connective tissue, and no reason why this should grow when the active villi are dead. The increased bulk of the placenta is brought about by organised blood clot, and we see no reason why the death of the fœtus should cause the effusion. The apparent reason for this belief seems to be that the alleged primary extra-uterine gestation, where the villi are supposed to graft themselves on the peritoneum, and where the placenta is necessarily stationary seemed to call for this alleged growth of placental tissue after the death of the fœtus as the only explanation of the unusual placental bulk. The primary grafting of the villi on the free surface of the peritoneum is, however, a myth, and so with its discredit its dependent myth of the placental growth after fœtal death must disappear. I believe, he says, that the increased bulk of the placenta is produced only during the life of the fœtus, and not after its death. In none of the four cases I have reported can I trace any special relation between the bulk of the placenta and fœtal death. In all, the fœtuses were well developed and near full time, and in No. I the fœtus was evidently not long dead. The real explanation of the increased size and altered structure is, according to Dr. Berry Hart, as follows :—We know that there is no primary peritoneal pregnancy, *i.e.*, no case where the placenta has had the free peritoneal surface as its internal portion. Advanced abdominal gestation has arisen primarily from a Fallopian tube gestation where the placenta remains in the extra-peritoneal tissue, or more rarely in the tube. The fœtus may also be extra-peritoneal or, by secondary rupture, may lie within or without the amnion in the peritoneal cavity. In this extra-peritoneal development of the placenta we have two things happening which do not occur in normal pregnancy. The extra-peritoneal placenta (1) develops a serous membrane which it separates from the subjacent tissue. (2) It is either displaced down and not extensively if the growing fœtus lies below. It is this extra-peritoneal burrowing and displacement that causes the blood effusion and connective tissue formation leading to the greater bulk of the placenta, and it can only happen during fœtal life. The alterations in the structure of the placenta when extensive, cause the death of the placenta, and in proportion as these are less profound are the children healthy (*vide Edin. Med. Jour.*, 1891, "On displacement of the placenta in extra-uterine gestation and its relation to these cases ending in pelvic abscess"). In the last case the placenta developed in the tube was not subject to displacement as in the first three, and thus held no marked increase in bulk and no great alteration in the structure of its fœtal portion."



8.—Transverse section of a chorionic villus of a normal placenta in the sixth week of intra-uterine pregnancy × 400. e. p. Double epithelial layer. c. t. c. Connective tissue cells. b. v. Blood vessels. r. b. c. Red blood corpuscles.

To take these points *seriatim*. I have already alluded to the hydatidiform degeneration of the placenta *in utero* as an example of growth of the fœtal portion of the placenta, that is to say, of the chorionic villi after the death and disappearance of the fœtus. Nor is the supposition of the continued growth of the villi necessary to any explanation of the exaggerated development of the placenta in certain cases. All that is sought to be shown is that it grows, that is, increases in size, and whether this be by the further growth of this or that special structure is immaterial to the issue, for the mere development of connective tissue stroma (which Dr. Hart appears to admit), constitutes growth.

The primary grafting of the villi on the peritoneum may or may not be "a myth," but the specimen from Mr. Tait's collection to which I have alluded shows that it can and does occur as a secondary process subsequently to rupture of a tubal gestation and extrusion of the partially detached placenta. There are indeed facts in abundance to prove its possibility, at any rate so far as the formation of vascular adhesions is concerned. In reference to the contention that the increase in size takes place during the life of the fœtus and not after its death it must necessarily be difficult to obtain documentary evidence either way. Even if this suggestion hold good, however, in respect of placental masses which have become hard, condensed, and practically extra-vascular, the placenta that may be removed with ease and safety by laparotomy—I do not see how it can apply in those cases where the placenta is still an extremely vascular structure intimately adherent to adjacent tissues. A living placenta —such as these are—means a growing placenta, for it is difficult to give any valid reason to believe that arrest of development would occur except as a consequence of the loss of vitality. The connection between the placenta and the fœtus in extra-uterine gestation is not essential to the vitality of the former, though, in general, the death of the fœtus leads automatically to an interference with the blood supply and congestive hæmorrhagic extravasation. Moreover, this view is inconsistent with the clinical observation that the tumour has gone on increasing in size up to the date of operation, although the examination of the specimen places it beyond doubt that the fœtus must have succumbed at some date long anterior thereto. The disappearance by absorption of a fœtus takes some time and consequently if, in a growing tumour, no fœtus be found it is presumptive evidence of growth subsequent to its death.

Conclusions.—From a careful study of the clinical facts for and against, I have been led to infer :—

1. That under certain circumstances, the nature of which cannot at present be specified, the vitality of the placenta in extra-uterine gestation survives the death and disappearance of the fœtus.
2. That under these circumstances further growth and development of the placenta may take place.
3. Hence that it is not safe to wait for evidence of the death of the fœtus before proceeding to remove the gestation sac, seeing that the continued growth of the placenta may at any moment determine either a primary or a secondary rupture of the sac wall, entailing sudden hæmorrhage, which will be the more formidable in proportion to the greater size which the placenta may have attained.

SOME RESULTS OF INFLUENZA: THEIR METHOD OF TREATMENT.

By F. P. ATKINSON, M.D.

There are few diseases which present such a variety of after-effects as epidemic influenza. Some of the sequelæ are more common than others, and consequently the general line of treatment with regard to these is pretty clearly defined, while others are comparatively rare, and afford but scant opportunity for forming correct conclusions as to how they may be best dealt with.

Some short time back I had what appeared to be an ordinary attack of influenza, inasmuch as the nasal discharge almost entirely subsided in the course of two days. But I soon began to experience a constant feeling of faintness, and *both nostrils appeared to be unusually blocked on lying down at night.* After a few doses of liquor strychniæ the faintness disappeared, but the blocking of the frontal sinuses became worse and worse, till at last it was utterly *impossible to get sleep except in the upright position* (*i.e.*, in an armchair), and then for a very short time. *On going into a hot room the difficulty of breathing through the nose increased, the cheeks became red and flushed, and at night the feet, and often the face, became burning hot,* though there was little or no rise of temperature. All the time the nose remained perfectly dry, and it was impossible to get any passage through it on blowing with a pocket handkerchief. *Steaming only seemed to have the effect of making it, if anything, worse.* The distress produced was really terrible, and the loss of sleep brought about such a feeling of exhaustion that at one time it appeared as if I should lose my reason. Nothing in the shape of medicine seemed to do any good, but boiling-hot *Bovril certainly gave me some relief* in about twenty minutes after it was taken. *On dry frosty days I fancied there was some improvement.* After being bad for about five or six weeks I went to see one of the chief London specialists, who confirmed my view of the case, viz., its being a vaso-motor paralysis, and told me that little could be done in the way of treatment—that in all probability it would go on for two or three weeks longer, and that if improvement did not take place as expected, a change to the seaside would be necessary. The local application of cocaine which I had been trying he said was of very little use, inasmuch as contraction of the blood-vessels first brought about after a time gave place to dilatation. A pill of strychnine and arsenic (gr. 1-24th of each) three times a day he thought might do some good ; but I fancied the pil. phosphori co. was of more service. Two days after my visit to London I was very much worse, and I then went to one of my local medical brethren and told him how really weak and ill I felt. He said he had a prescription for a snuff which had been extracted from the *Lyons Medical Gazette*, and although he did not know its effect, advised me to try it. It consisted of 1 grain of cocaine, 2 grains of menthol, and 100 grains of boric acid. Within a few minutes of taking the first pinch I obtained a marvellous relief for about an hour, and by its continued use I got more and more ease till at last the necessity for it almost entirely disappeared.

When speaking to another medical man about my own case a short time after, he told me he had suffered for a year or two past with naso-pharyngeal catarrh and throat deafness following upon influenza ; that he had consulted an eminent London throat specialist who had recommended various inhalations and throat sprays, but without much benefit resulting. I then suggested he should try the same kind of snuff that had proved of such service to me, and the result he subsequently told me was beyond his expectations. In about a week or two he was almost entirely free from his throat trouble, and could hear perfectly well. Of course, as he said, he had to use it occasionally, but it always gave him relief.

I cannot help thinking it might prove useful in some cases of ozæna, post-nasal diphtheria, relaxation of the posterior palatine arches, and hay fever. At any rate, it demands a trial.

Surgeon-Lieut.-Colonel B. Franklin, Indian Medical Service, has been appointed Surgeon to the Staff of the Viceroy of India.

Selected Prescriptions and Therapeutic Notes.

94.—A useful Expectorant in the Broncho-Pneumonia of Children :—

℞ Ammon, acetatis, } āā ʒiiss ;
Sodæ benzoatis, }
Sp. vini gallici, ʒss ;
Syr. tolutani, ℥iss ;
Syr. acaciæ, ℥ij.

M. A teaspoonful every two hours, increasing or diminishing the dose according to age.—*Lancet—Clinic.*

95.—The Treatment of Epistaxis :—

For many years, Mr. Hutchinson says, that he has never in any single instances adopted the plan of plugging the nostrils for severe epistaxis. Since, however, he has adopted the practice of placing patients suffering from continuous hæmorrhage from the nostrils in the sitting position, and with the feet in a deep foot-pan of very hot water, he has never once failed in arresting the bleeding.

96.—A Simple Means of Rendering Water Sterile :—

According to Constantine Paul a very simple means of rendering water sterile is to add alum to it, in the proportion of about four grains to a pint. The solution has no taste, and it is readily prepared. No cultures can be obtained from water so treated, it is alleged, at the end of twenty-four hours, but micro-organisms re-appear at the fifth day.

97.—To Reduce the Pyrexia of Phthisis :—

℞ Quiniæ sulph, gr. iiss ;
Pulv. digitalis fol., gr. ss ;
Extracti opii, gr. 1-8th ;
Extracti belladonnæ, gr. 1-8th.

M. To make one pill. Two to be taken every six hours.

98.—A Useful Cough Mixture in Phthisis :—

℞ Liq. atropiæ sulph., ♏xij ;
Syr. codeinæ, ℥iss ;
Infus. rosæ acidi, ad ℥vj.

M. One tablespoonful when necessary.—The Pharmacopœia of the Royal Infirmary, Edinburgh.

99.—For Disinfecting the Air of a Sick Room :—

℞ Ol. eucalypti,
Acid. carbolici, āā ℥j ;
Ol. terebinthinæ, ℥vij.

M. One tablespoonful to a quart of water ; some of this solution should be allowed to simmer constantly over a spirit lamp.—J. Lewis Smith.

100.—For Vaginismus :—

℞ Thymolis, gr. iij ;
Ext. belladonnæ, gr. xij ;
Pot. bromidi, ʒss ;
Ol. theobromæ, ʒiv.

M. To make four suppositories. One when necessary.—De Sincty.

101—For Psoriasis :—

℞ Papainæ, ʒiss ;
Acid. salicylatis, ʒss ;
Glycerini, ʒiiiss ;
Ung. zinci ad ℥ij.

M. To be applied over the affected surfaces.

Egbert.

102.—A New Emmenagogue:—

Dr. Murrell publishes in the *British Medical Journal* an interesting paper in which he gives the result of his investigation of the emmenagogue properties of the *Senecio Jacobœa*, or common rag weed. He made a tincture of it, and administered half drachm doses three times daily with, he says, excellent effect. No doubt it might also be used by infusion.

◆

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, March 30th, 1894.

The President, Mr. J. W. Hulke, F.R.C.S., in the Chair

RESECTION OF A PORTION OF THE LEFT LATERAL WALL AND BASE OF THE BLADDER FOR RECURRENT EPITHELIOMA.

Mr. **Hurry Fenwick** read the history of a patient who had been under the care of Dr. Mackenzie, of Caerphilly. The symptoms were typical of villous growth of the bladder, but electric cystoscopy revealed a small tough epithelioma of the left base. Mr. Fenwick removed this perineally in May, 1891, and Mr. Targett reported that the tumour microscopically was a malignant epithelial growth. Symptoms recurred in a year's time. Suprapubic cystotomy was, therefore, performed, and the tumour thoroughly removed, and the base seared with Paquelin cautery. Seven months afterwards, the symptoms again recurred. The tumour and the left lateral wall and base of the bladder, upon which it was placed, was completely resected supra-pubically. The usual vertical incision being extended laterally through the left lower abdominal wall, the wound healed *per primam.* The patient now, nine months after the operation, is apparently in good bladder health, holding his urine from four to seven hours, and he has gained in weight. Mr. Fenwick only advises resection when the epithelioma is primary, tough, single, and small, when the submucous tissues are found glued to the base of the growth, and only in those cases where the "vis" of the patient warrants so severe an operation. He believes that separation of the symphysis pubis will be but rarely needed.

Mr. **Gould** asked whether any difficulty had been experienced in bringing together the edges of the bladder wound and whether any leakage took place ; also as to how far up it was found necessary to strip the bladder of peritoneum.

Mr. **W. G. Spencer** asked why a drainage tube had been left in seeing that there was no urethral obstruction and the urine was healthy.

Mr. **Fenwick**, in reply, observed that though primary union of the vesical incision might be hoped for in children it was otherwise in adults. Under these circumstances he thought it better to leave in the tube. When the growth involved the peritoneum it was better to leave it alone. He had raised the peritoneum to a level with the posterior reflection.

Mr. **Christopher Heath** contributed

TWO CASES OF RECTANGULAR ANKYLOSIS OF THE HIP TREATED BY OPERATION.

The first was in a girl, æt. 14, with complete osseous ankylosis of the hip at a right angle, but with no sinuses and no dislocation. Division of the neck of the femur by Adams's method was performed, but considerable difficulty was encountered in overcoming the contracted condition of the muscles. Eventually an excellent straight limb was obtained. The second patient, a girl, æt. 19, had dislocation of the head of the femur with sinuses leading down to the bone. Division of the femur between the trochanters (Sayre's operation) was performed with complete success. Photographs of the patients before and after the operation were shown, and the patients were exhibited.

Mr. **Bowlby** did not think Adams's was the best operation in hip ankylosis following hip-joint disease because there was a danger of spreading the infection by the saw which passed through the diseased tissues. Moreover, the neck of the femur might be very much thickened or even absent. In such cases he preferred to divide the femur below the inner trochanter so that when the lower limits were brought together the pelvis might be tilted backwards on that side.

Mr. Keetley pointed out that rectangular deformity could not be remedied without removing a wedge-shaped piece of bone at the same time dividing the soft parts freely. He had operated on some 30 cases of strumous hip disease, and in all except one healing had rapidly taken place.

The President observed that the important thing was to fix the limb so that if ankylosis did take place the limb would be in the most useful position for the patient.

A CASE OF BILIARY COLIC RELIEVED BY OPERATION.

Mr. Arbuthnot Lane read a report of a woman, æt. 35, who, one year and ten months ago, had her first attack of biliary colic; since that time she had attacks at frequent intervals, the attacks being more severe and the intervals shorter as time went on. At an early period the jaundice remained after the attacks had passed off, and for many months before her admission her motions had been white and pasty. She lost flesh and strength very rapidly. She was attended by Dr. Chubb, of Sandgate, from October, 1893, and during that time her temperature was high in the evening, and during her attacks of abdominal pain, tenderness, distension, and increased jaundice it was very irregular. She was admitted on December 11th, 1893, in a very wasted and prostrated condition, an exacerbation or attack having just developed. Her abdomen was very distended, tender, and painful, especially between the edge of the liver and umbilicus. The edge of the liver could be detected by sitting her up, and the gall bladder could not be felt. During the six days following her admission the temperature was so irregular as to suggest the presence of pylephlebitis, but after that, the so-called attack subsiding, the temperature became regular, rising every night to 103° or more. On December 21st by means of a long vertical incision, Mr. Lane found the gall bladder flaccid and containing some mucus and three small stones, which yielded a strong fæcal odour. There was a stone fixed in the cystic duct, and several large ones in the common bile duct, two being behind and also below the level of the first piece of the duodenum. A small incision was made into the common duct, when a large quantity of clear mucus of a strong fæcal odour was gradually allowed to escape and was carefully removed. On attempting to get at the calculi, a free escape of what was apparently fluid fæces took place from the opening in the duct. The incision into the duct was carefully sutured, a tampon of iodoform gauze was introduced into the peritoneal cavity, and through its centre a glass tube was placed with its orifice close to that in the duct. The stone in the cystic duct was not removed, as it was hoped it would prevent the exit of bile by the gall bladder which it served to do effectually. The patient was much improved by the escape of the dammed up mucus. On the 24th, the tampon was found satuated with bile of a fæcal odour. It was removed and replaced, the bile subsequently escaping freely through the glass tube. On January 3rd, the opening in the duct was enlarged sufficiently to allow of the introduction of the finger when the stones were broken up, and a large quantity of *débris* and fluid of a stercoraceous character evacuated. It appeared as if one of the stones projected into the second piece of the duodenum. After a few days, the urine lost its tinge of bile, the fæces regained their normal colour, the opening in the abdominal wall closed, except where the gall bladder opened, and from it mucus continued to escape. The patient rapidly gained health and strength. Mr. Lane called attention to the peculiar character of the so-called attacks, and pointed out the remarkable simplification of such operations by the use of the gauze tampon. Although normal bile had no deleterious influence on the peritoneum, the secretions of the liver, as the surgeon meets them in cases in which he is obliged to open the common hepatic and common bile ducts, probably always contain organisms capable of setting up a fatal peritonitis.

Mr. W. H. Battle on a case of

TRAUMATIC RUPTURE OF THE COMMON BILE DUCT.

A boy, æt. 6, was admitted to the Royal Free Hospital on the 15th August, 1893, having been run over by a hansom cab. There was but slight shock, no bruising of the abdomen or special tenderness. He vomited soon after admission. The case was regarded as one of "contusion" of the abdomen. On the third day the urine was noticed to be high-coloured, the temperature was 101°·2 in the evening. He vomited occasionally and was restless. On the fourth day respiration was spasmodic and entirely thoracic. The bowels were acting and he had vomited. Temp. 6 p.m. 102°·3. On the fifth day still restless and looking ill. Slight jaundice present. On account of the vomiting nutrient enemata was commenced. Sixth day, slight dulness in right side of the abdomen, vomiting more troublesome, temperature normal. Seventh day, much worse, looking very ill, with sunken eyes, deeply jaundiced and much emaciated, frequent vomiting in the manner of those suffering from peritonitis, pulse rapid, dorsal decubitus with flexed thighs. The condition of the abdomen was one of flaccid distension, it moved with respiration, but chiefly in the upper part, was but slightly tender and without muscular rigidity. Dulness extended from the hepatic region into the right iliac fossa, there was also slight dulness in the left flank, on the right side this dulness extended forward as far as the linea semilunaris, and changed but slowly, if at all, with the position of the patient. Was restless and peevish, and gave an occasional deep sighing inspiration. Mr. Battle, who saw the case for the second time on this day, expressed his opinion that the fluid in the peritoneal cavity was bile, probably mixed with some inflammatory effusion. That the supply was through some small opening in the duct apparatus, and not due to rupture of the gall-bladder or liver substance. He proposed abdominal section, but was not able to do this until twenty-four hours later, when the condition of the child was much more grave. At the operation an incision was made in the right linea semilunaris and a good deal of almost pure bile evacuated, more than three ounces being collected. The weak state of the patient prevented any prolonged examination, and nothing abnormal could be felt with the finger. The coils of intestine were congested. He died on the morning of the ninth day. At the post-mortem examination made by Mr. W. H. Evans the whole of the intestines were found to be injected and to have thin layers of lymph on them, this was especially marked on the right side. The liver and gall bladder were intact, but about half an inch beyond the junction of the cystic and hepatic ducts, the common bile duct was found to be torn transversely completely through, but the aperture was difficult to find. No other traces of injury were found. Bile was absent from the motions during the last two days of life only. Mr. Battle pointed out the usual course of symptoms in this class of cases, the history of a severe injury followed by some shock and few definite abdominal signs until some days had gone by. Then the appearance of fluid in the abdomen, only cured by repeated tappings. This was the only case he could find of complete transverse rupture of the duct without laceration of liver. He referred to known cases, in some of which partial rupture was proved to have taken place at the necropsy, others in which, after similar symptoms, recovery had ensued, and to others in which although the conditions locally after death, and the general symptoms during life were similar to the first group, yet no communication with the ducts was proved.

A CASE OF ANEURISM BY ANASTOMOSIS.

Mr. G. R. Turner read notes of a case of aneurism by anastomosis, said to be congenital, which occupied the right temporal region of a girl, æt. 16, and which had been increasing in size, extending on to the right eyelid and cheek. The skin covering the tumour was thin and discoloured, giving it a nævus-looking appearance. Examination under an anæsthetic showed the tumour to have grooved the bones, but to have no intracranial communication. Several dilated thin-coated vessels were exposed in the normal situation of the temporal artery and ligatured. Pressure was made on the growth, and was followed for a time by marked improvement. Pulsation ceased and the bruit and thrill disappeared—to reappear, however, in a few weeks' time. Various vessels at the outer canthus and in the frontal region which appeared to feed the growth were then ligatured and pressure again employed. These proceedings were followed by temporary improvement only. The girl returned home, and although there lately has been some further extension of the swelling, her parents refuse any further treatment. Mr. Turner remarked that, according to Gosselin's classification, this was a case of aneurism by anastomosis rather than arterial varix or cirsoid arterial varix. From the capillaries and skin being implicated, excision of the mass was impossible, and had he obtained permission from the parents he would have ligatured the external carotid artery. He did not think that surgeons of the present day should be deterred by statistics of a past age, before the introduction of antiseptics and the use of absorbable ligatures, from ligaturing either this vessel or indeed the common carotid artery in such cases as the one recorded. He drew attention to frequency of the temporal region as the affected side, and mentioned a case he had seen occupying the whole of one side of the scalp.

Mr. W. G. **Spencer** observed that electrolysis might have been tried after ligature of the vessels, and if that failed, the tumour might have been excised followed by skin grafting to fill the gap.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, March 9th.

The President, Dr. **Purefoy**, in the Chair.

OVARIES AND TUBES REMOVED FOR DYSMENORRHŒA.

Dr. Alfred Smith showed tubes and ovaries removed from a patient, æt. 35, in his gynæcological ward of St. Vincent's Hospital. The patient was a schoolmistress, and for the past eighteen months suffered intensely during the menstrual periods; the pain was most agonising, and the flow very profuse. She was curetted on several occasions without benefit. She was kept in bed for two months, again curetted, and dosed with the usual remedies recommended for dysmenorrhœa without the slightest improvement in either the intervals of the pain or the heaviness of the menstrual discharge. The uterus felt very large and knobby, as if studded with small myomata. The tubes and ovaries were all adherent and hard to palpate. Nothing was to be done except to arrest the menstrual periods. Accordingly, on Feb. 22nd, the tubes and ovaries were removed. The patient suffered great pain after the operation, due to metrostaxis; the pain was only relieved when a discharge of blood from the uterus occurred. On the third day after operation an attack of pseudo ileus supervened; this was relieved by a turpentine enema. Her recovery from this was rapid and uneventful. Stitches removed on eighth day, union good.

Dr. **Atthill** said that there were some severe cases of dysmenorrhœa which justified removal of the ovaries. In a case in which he had performed the operation the patient was compelled to spend three weeks out of four in bed, and she was also a nun. She is now quite well.

CASES OF UTERINE MYOMATA TREATED BY INJECTION OF ERGOT.

The **President** detailed some cases of uterine myoma suffering from pain, hæmorrhage, and—in one case—troublesome vomiting. Injections of ergot in two cases caused the disappearance of the tumour; in nearly all controlled the bleeding and relieved the pain, and in one case stopped the vomiting also. In only one case was there trouble from sloughing of the tumour. In one the hæmorrhage was checked, and removal of the ovaries effected a cure. The preparation used was Squibbs' ergot—a syringeful the amount generally used—at intervals of several days, and in no case was abscess caused by the treatment.

Dr. **Smith** said that at the present day, when one hears so much of operative gynæcology, it is in some cases useful to adopt less dangerous methods. The list of cases—small though it is—brought forward by the President shows that there are a certain number of cases which can be benefited by the hypodermic injection of ergot. It is remarkable that in his cases the women were nearly all at the centre of their child-bearing period. His own experience with regard to ergot hypodermically for these cases was unfavourable. When Assistant Master of the Rotunda he had tried it regularly in two or three cases without benefit, and the local annoyance following the injections rendered the patient's lives miserable. He would like to ask the President in what class of cases he would recommend ergot hypodermically.

Dr. **Atthill** said that he had given this treatment a fair trial in the Rotunda many years ago, and had been unfavourably impressed by it. He had found local abscesses which caused considerable trouble to follow his injections. He had used three preparations, none of which were "Squibbs," which was not then in existence He had employed it in one remarkable case. There was a large fibroid projecting into the interior of the uterus. He dilated the uterus and removed a large portion of it. He then gave the patient ergot hypodermically. This caused such violent pains that he was forced to give it up. He concluded that ergot will not originate uterine contraction in a healthy woman, but that it will do so where there is a mass in the womb ready to be expelled. In consequence, he had given ergot in all cases of threatened abortion. If it does not expel the ovum it acts as a tonic to the uterus.

Dr. **Purefoy**, in reply, stated that this treatment was useful for those class of patients who were scared by the very mention of the word operation, and also in those cases in which the fibroid was intra-mural and not projecting into the cavity of the uterus in a polypoid form, nor existing as a pedunculated sub-peritoneal fibroid.

OVARIOTOMY ON A LUNATIC AND LIFE HISTORY OF A UTERINE FIBROID.

Dr. **Lombe Atthill** detailed the particulars of a case in which he watched the growth of a uterine fibroid from nearly its earliest stage, till it attained the size of a fœtal head at full term, its growth being attended by profuse, sometimes alarming hæmorrhage About two years and a half ago she became insane, and was admitted into an asylum, shortly after which menstruation ceased to recur. Recently her attendant observed her size to increase rapidly, and Dr. Atthill being requested to see her, diagnosed a large ovarian cyst. Ovariotomy was performed by him, and the opportunity was taken of examining the condition of the uterus. It was found to have atrophied to such an extent that it was but little larger than the healthy organ should be previous to the occurrence of the climacteric period. This rapid atrophy was doubtless accelerated by abstinence; specially during the first month of insanity she was with difficulty induced to take any food, and at present barely sufficient to support life. Although she could not be prevented from sitting up in bed frequently, even on the day on which the operation had been performed, she made a rapid recovery after it, the temperature only once rising to 100°; that was on the day succeeding the operation. She was stated to be in her fiftieth year.

The Section then adjourned.

◆

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, March 15.

The President, Mr. **George Eastes**, in the Chair.

DEBATE ON INFLUENZA.

Dr. Samuel West opened the discussion. The author said he proposed to consider in the introduction to the discussion chiefly what was striking and peculiar in the disease rather than what was common. The onset was often very sudden, though rigors rare, occasionally by sudden collapse, generally described as a fit, but usually only a faint. Hysterical attacks were not rare, but convulsions almost unknown. Where a patient became drowsy or comatose, the diagnosis of meningitis, or even cerebral hæmorrhage might be made. Fever was moderate, hyperpyrexia rare, apyretic influenza not uncommon; the post-febrile depression was remarkable, being often as pronounced as after typhoid fever, and that too after quite mild cases. This stage was important, as during it complications were likely to arise from want of care and from exposure. Neuro-muscular depression was one of the prime characteristics of the disease. Of other nervous symptoms the most important were the angina-like attacks, which had fortunately been rare in the present epidemic, though very common in 1848. Of digestive disturbances, the most remarkable was loss of taste, usually continuing only during the febrile stage. Intestinal colic, or rather visceral neuralgia, had not been uncommon. Sweating was usually as profuse as in rheumatic fever, but confusion between influenza and rheumatic fever, though possible, was not likely. Rashes, chiefly of an erythematous type, were not really common when reckoned out in percentages. Attacks of sudden collapse were common, sometimes occurring at almost regular intervals. They might continue even into convalescence. They affected both heart and respiration, and were probably central in origin. This form of influenza deserved recognition by a special name as much as the other named varieties, and might be called the collapsing form. These collapses were usually unattended by dyspnœa or cyanosis, and differed on the one side from the angina attacks which were neuralgic, and from true cardiac failure, which also occurred, but which was more prolonged, less transient, and usually associated with signs of pulmonary congestion and dyspnœa. Of the nervous symptoms, the chief have been referred to, but delirium and sopor, and even unconsciousness were now often met with, and these created difficulties in diagnosis. Of the complications, those of the respiratory organs were the commonest, and it was to bronchitis and pneumonia that most of the deaths were due. In illustration of this the statistics of pneumonia at St. Bartholomew's Hospital were referred to, the number of cases admitted into the hospital being doubled during the influenza years, but the fatality of influenza-pneumonia was not above the usual average. The peculiarities of influenza-pneumonia were referred to. It was throughout atypical and asthenic. It fell specially heavily upon the middle period of life. When of broncho-pneumonic type it might resemble phthisis, especially if attended with hæmoptysis. Cases of the kind were quoted. Its relation to phthisis was important. It often started existent tuberculosis into fresh activity, and was always serious in persons with damaged lungs, but it seemed sometimes to actually lead to phthisis in persons previously healthy, and then phthisis ran a rapid course. In some cases a hæmorrhagic tendency seemed to develope. Instances were referred to of troublesome bleeding from the lung, nose, bowel, and vagina. The effect on other diseases was considered. Some cases in which cancer had appeared to follow were referred to. Certain other complications were referred to, notably in the ear and eye, but many of them were clearly due to accidental association. Of nervous sequelæ the least rare were peripheral neuritis and general tremor, or shakiness. Infection.—Influenza was a germ disease, therefore communicable, but not necessarily infectious, *i.e.*, conveyed directly from sick to healthy. Many instances of direct infection were recorded, but more numerous were the instances in which infection had failed to follow. Therefore there was probably some other indirect mode, perhaps through the air. One attack gave no protection, indeed, it almost seemed as if one attack rendered the patient more liable to have another. Reference was made to treatment. No specific was known, and treatment was chiefly symptomatic. The most useful drugs were strychnine, and citrate of caffeine.

Dr. **Kanthack** demonstrated pure cultivations of influenza bacillus on broth, gelatin, and agar-agar. He gave a short review of the history of the discovery of the influenza bacillus, and said that it was highly probable that this bacillus was the cause of influenza, since it was always found in the bronchial secretion during that disease, and never in any other affection. Experiments on rabbits, monkeys, and horses had led to positive results. The bacillus was not often found in the blood, and when found was always dead or its vitality was greatly impaired. He showed that the bacillus grew well on artificial media at 37° C. Specimens were shown under 1·12th inch objectives both of influenza bacillus and of the streptococcus of pneumonia.

The **President** thanked Dr. West for his excellent account of the medical aspects of the disease, and Dr. Kanthack for his microscopical specimens of the microbe of influenza. He referred to the occasional difficulties of diagnosis, as shown in the case of a young woman that terminated fatally, in which, *post mortem*, universal cerebral meningitis was found, and that alone. At the onset of her illness the symptoms seemed to be those of influenza, though of an aggravated type; but eventually the symptoms of meningitis became paramount. In another fatal case (a gentleman, æt. 44) seen by him, there was for many days a rapid, extremely feeble pulse. Pneumonia supervened, and the feet became quite cold and gangrenous about a week before death, which occurred on the 18th day of the illness. After death the main arteries to the feet were patulous. There was no embolism, and the gangrene was apparently due to the cardiac asthenia.

Mr. **D'Arcy Power** hoped that some evidence as to the incubation period of influenza would be adduced in the course of the discussion. In his own case the incubation had twice been a period of eight days. On the last occasion he had vomited on Saturday night, but felt no aftereffects until the following Sunday week, when he was suddenly attacked in the ordinary manner. Mr. Power also referred to a case of influenza occurring in a child a few months after it had been vaccinated. The only surgical sequelæ of influenza with which he had met were cases of tenosynovitis. This affection appeared to be more frequent in the last epidemic than in either of the previous ones.

Mr. W. **Sedgwick** commented on the great tendency to death from failure of the heart's action in cases of influenza in old patients, and especially in those who had a strongly marked and constitutional tendency to gout. In such cases he had found successive doses of strychnia given by hypodermic injection a valuable remedy, which of course needed to be carefully watched, as it was often necessary, in exceptionally grave cases, to push it to the extent of producing distinctive twitchings.

Mr. W. H. **Lamb** stated that in an outbreak of influenza in a girls' school marked desquamation had followed some cases with a rash resembling that of measles, others that of scarlet fever, and also in cases where no rash had occurred.

Mr. **Cripps Lawrence** referred to two cases in which influenza was followed by, and modified the course of, typhoid fever. The duration of the fever was unaltered, the spots were smaller than normal, but regarded as typical; the nocturnal rise in the temperature occurred; no diarrhœa; in one case three stools of a typhoid character were observed; in both the general character of the stools was abnormal, being dark. Both cases exhibited marked vital depression.

Dr. **Hazel** said that he had lately had many cases of influenza occurring in pregnant women under his care. It seemed to exercise a most pernicious effect upon pregnancy, as it frequently brought on premature labour, and was also a cause of miscarriage. He had had two cases of typhoid fever which were at first mistaken for influenza. In another case diagnosed as influenza of the gastric type, which was removed to hospital for treatment, variola definitely manifested itself on the third day.

Dr. **St. Clair Thomson** considered that Dr. West's paper gave such a complete clinical picture of influenza that members could only supply additions by recounting exceptional cases not met with in daily practice. With regard to Dr. West's remark of the effect of influenza in surgical affections, Dr. St. Clair Thomson had seen some cases of suppuration of the accessory cavities of the nose apparently consequent on influenza. They differed from ordinary empyemata in the tendency they showed to spontaneous cure. Dr. Semon had put a similar personal experience on record. In the clinics of Politzer and Gruber, it had been found that mastoid suppuration followed otitis media much more frequently after influenza than after ordinary catarrh. The anatomy of the parts concerned did not favour natural cure as in suppuration of the nasal sinuses.

Dr. **West** having replied, the meeting adjourned.

◆

LARYNGOLOGICAL SOCIETY OF LONDON.

Meeting held March 14th.

Felix Semon, M.D., F.R.C.P., President, in the chair.

CASES.

Fixation of Left Vocal Cord.—Dr. J. B. **Ball** showed a case. The left vocal cord was immovable in position of complete paralysis. Right vocal cord moved freely. No other sign of disease in larynx. The paralysis followed influenza and congestion of the lungs. She lost her voice during the illness, and it had never returned to its natural condition. Suffered from palpitation of heart. The feet and legs swelled at times. Never had rheumatic fever. Heart's apex beats in fifth space, an inch outside nipple. Systolic and pre-systolic apex murmurs present. Lungs normal.

Dr. J. B. **Ball** also showed a case of Tumour of the Larynx in a Case of Goitre. The large goitre had been growing for ten years and was beginning to cause some dyspnœa. A considerable portion of the tumour had been removed eighteen months before. Larynx at that time was normal. In August, 1893, tracheotomy had to be performed, and she had worn tube since. The larynx was examined, and a swelling was found involving right ary-epiglottic fold and almost hiding glottis. Not examined again till March 9th, 1894, when a rounded, smooth red swelling was seen involving the right ary-epiglottic fold, and covering nearly the whole of the aperture of the larynx. Since the original operation in September, 1892, there had been a considerable increase in the size of the portion of the goitrous tumour which was left.

Laryngeal Symptoms in a Case of Insular Sclerosis.—Dr. F. W. **Bennett** showed this case. R. P—, æt. 38, complained in April, 1892, of difficulty in swallowing, hoarseness, and attacks at night-time as if "some one were clutching the throat, preventing breathing." On examination the pharynx and larynx were found chronically inflamed, the uvula elongated. During inspiration the cords separated widely, the right moving most freely. In phonation the right cord moved slightly over the middle line, but the left moved fairly freely. The vocal processes met, leaving an oval opening between the cords anteriorly and a triangular opening posteriorly. Occasional tremor of the cord was noticeable. The patient was thought to be suffering from insular sclerosis.

Case of Tracheal Fistula.—Dr. **De Havilland Hall** brought forward the case of M. S—, æt. 40, on whom tracheotomy was performed at the age of twelve on account of gradually increasing difficulty of breathing. A cannula was worn up to the age of nineteen, but a tracheal fistula remained after its removal. Closure of the opening with the finger caused dyspnœa. On laryngoscopic examination the glottis was found to be very much contracted by papillomatous growths springing from the vocal cords and the anterior commissure. After these were removed with the cutting forceps, Mr. Pearce Gould did a plastic operation, and closed the tracheal fistula, which had existed for twenty-one years.

Dr. **De Havilland Hall** also showed a specimen of Syphilitic Stenosis of Larynx, from a patient who was shown at a previous meeting of the Society suffering from syphilitic stenosis. During a wrangle in the street the cannula came out, and being unable to replace it, the patient was brought into the hospital dead.

Mr. **Spencer**, who had originally performed tracheotomy in this case, observed that there had probably been some amount of neuritis of the superior laryngeal nerve, and it was most likely that the sudden death was not due merely to the loss of the tube, but to some sudden disturbance of the heart's action.

Dr. **Hall** agreed with this view, and mentioned that the patient had on several occasions suffered from syncopal attacks and vomiting.

Dr. **Percy Kidd** showed a case of Laryngeal Stenosis (? Tubercular), and a case of Small Subglottic Tumour of Uncertain Nature in a Case of Laryngeal Tuberculosis. *Larynx.*—Puckered and partly healed ulceration of tip of epiglottis. Ventricular bands much swollen, partly hiding vocal cords. Ary-epiglottic folds both much swollen. In subglottic region just below anterior commissure, and slightly to the left of the middle line, a sessile, oval, smooth, reddish tumour, of the size of a coffee bean. The tumour had been under observation for three months, and no change had occurred in its appearance. Tubercular ulceration of the epiglottis was arrested by the application of pure lactic acid. The patient suffered from chronic pulmonary tuberculosis.

Malignant Disease of the Larynx cured by Thyrotomy and Excision of the New Growth.—Dr. **Semon** exhibited two cases:—Case 1 has been already described in Clinical Society's "Transactions," vol. xxv, 1892, p. 300. Case 2.—The Rev. Canon B—, æt. 59, suffered from a bipartite growth occupying the posterior part of the left vocal cord, which extended almost to the arytænoid cartilage; the cord showed a very slight defect of mobility. The voice was marvellously clear in spite of the situation and considerable size of the growth and of the general congestion. The patient complained of pain felt in the left side of the throat, and of tenderness on pressure of the left side of the larynx. There was also some blood-stained expectoration in the mornings. Thyrotomy was performed, and the left vocal cord, together with a part of the left arytænoid cartilage, removed. The growth, on microscopic examination by Mr. Shattock, turned out to be a cavernous fibro-sarcoma. The patient recovered without the slightest incident, and in his case too the voice was nearly normal, a cicatricial ridge having formed in the situation of the former vocal cord very much as in the first case.

Dr. **Semon** observed that this tendency to the formation of cicatricial ridges doing duty for a removed vocal cord did not appear to be an isolated phenomenon, exactly the same formation having also been observed in the case of the late Mr. Montagu Williams.

Laryngeal Neoplasm of apparently Sudden Origin (Pachydermia).—Dr. **Scanes Spicer** showed this case. The patient had complained of hoarseness of about fourteen days' duration, which came on with a severe cold. Voice was clear and strong before this attack. History of catarrhs, syphilis, rheumatism, and alcoholic excess, though latter not recent (ten years ago). In region of right processus vocalis was a small oval swelling with long diameter parallel to vocal cord, papillated on surface, reddish in colour, and on phonation dipping into reddened depression on opposite cord, but there was no hyperplasia. Cord mobility perfect. Slight thickening on posterior wall. Mucosa generally red and rough. The question must remain open whether the neoplasm had arisen suddenly, or whether, during the present catarrh, a sudden increase had taken place in a mass previously too small to cause hoarseness.

Case of Pachydermia Laryngis.—Mr. C. J. **Symonds** exhibited a patient, a tailor, æt. 52, suffering from pachydermia laryngis, who stated that his voice had been affected since a boy. He had served in the army and navy. He then drank spirits, beginning as a boy with rum, which he took daily. Ten years ago he became a teetotaler and remained so till three months ago. He said he had never drunk to excess. The principal elevation was on the left side. The summit was yellow and depressed. On the right the projection was much smaller, and was more definitely arising from the inner aspect of the cord. The man had taken iodide of potassium for a month with the effect apparently of reducing the prominence and rendering it more glazed. He had had syphilis, and recently had nodes on his tibiæ. His face showed much acne. The points of interest were the definite evidence of syphilis; and the early consumption of alcohol, followed by a period of abstinence.

Mr. C. J. **Symonds** also exhibited a specimen showing the presence of a lunated fold on the outer wall of the nasal fossa, opposite the anterior extremity and the middle turbinated bone. It was convex forward, and ran from above downwards and backwards. Behind and above it was the opening into the antrum. It might perhaps represent the fold usually found below the orifice of the antrum, somewhat anteriorly situated. In order to expose the meatus, Mr. Symonds was in the habit of cutting off this fold with a knife, or removing by an antero-posterior acting curette.

Tracheal Stenosis (? Cicatricial Stricture).—Dr. **Percy Kidd** exhibited this case. The patient, æt. 38, had had syphilis thirteen years ago with secondary skin eruption and sore throat. For the last two years he had suffered from an irritable cough with profuse expectoration. About the middle of January, 1894, he first noticed dyspnœa on slight exertion, and stridor both inspiratory and expiratory. No recession of soft parts. *Pharynx.*—Scarring of posterior wall and soft palate. *Larynx.*—Vocal cords pinkish, but movements normal. The trachea could be seen for a considerable distance. There appeared to be a narrowing of the lower end, but the bifurcation was not visible. *Chest.*—Breath-sounds weak over both lungs, expiration prolonged. Snoring sounds heard with inspiration and expiration. No other abnormal sign.

Case of Adductor Paralysis of Left Vocal Cord.—Dr. **Herbert Tilley** showed a patient, R. H., æt. 23, who came to hospital five months ago complaining of "sore throat," which produced a slight choking sensation, and was usually worse in the morning. There was complete paralysis of the left vocal cord, but no swelling of the arytænoids or ary-epiglottic folds. Tubercular mischief was present in both apices.

Dr. TILLEY suggested that pressure of enlarged bronchial glands might produce paralysis, but did not know of any cases.

The PRESIDENT had seen a few cases which could only be attributed to the pressure of such glands.

Case of Advanced Tubercular Disease of Larynx.—Dr. HERBERT TILLEY exhibited a patient, Mrs. G., æt. 31, who could swallow without difficulty any semi-solid food, but the epiglottis had almost completely disappeared, only a small stump being left.

France.

[FROM OUR OWN CORRESPONDENT.

PARIS, March 31st.

TREATMENT OF PHTHISIS.

DR. CHAUMIER, of Tours, strongly recommends carbonate of creosote, or creosotal, in the treatment of tuberculosis of the lungs, which has the advantage of being able to be taken by the mouth without irritating the digestive tract. Discovered in 1891 by Heyden, it presents a syrupy appearance, yellow, or dark brown if not well made, with a very slight odour of creosote. It is insoluble in water, and contains 94 p.c. of creosote. M. Chaumier gives from twenty drops to one drachm daily to children, and two to four drachms to adults in teaspoonful doses. These doses can be exceeded without danger. One of the first effects of creosote is to increase the appetite and the strength of the patient; the cough then diminishes, and finally the pulmonary lesions. No irritation of the stomach or intestines is produced by the highest doses. Employed on twenty patients, the result was very satisfactory, and M. Chaumier is convinced that in future creosotal will be the best remedy for that decimating disease.

ANTHROPOMETRIC PHENOMENA.

It is well known that Dr. Bertillon has been the inventor of the method of identifying prisoners by the peculiar features they may present, or by the measurement of the different organs, such as nose, eyes, ears, mouth, &c. Already the identification of 150,000 individuals is classed according to their minutest details and preserved in the great Paris depôts. The most remarkable phenomena are those of individuals with palmar hands and feet, 10 out of every 10,000; afterwards, in order of frequency, come those who enjoy the possession of eleven or twelve fingers, the little finger being the most frequently doubled. The presence of three ears has been several times noticed, and also that of three, four, five, and even six nipples. As monsters, M. Bertillon possesses a child with a calf's head (*à tête de veau*), a man with hands and feet like the paws of a dog, and another who possesses a fine mane on the back. As has been seen, a Barnum could make an excellent choice for an interesting museum.

DEATH FROM COCAINE.

At the Société de Chirurgie, M. Reclus reported the death of a man from injection of cocaine into his urethra. The patient, æt. 72, suffering from a cardiac affection, with sclerosed arteries, was treated for retention from enlarged prostate by tapping, it being found impossible to pass a catheter owing to the obstruction.

The following day another attempt was made to pass the catheter, but in vain, and to facilitate, before recurring to an operation, the entry of the instrument, an injection of six drachms of a five per cent. solution of cocaine was made. Immediately the man's face became livid, seized with a violent rigor, he sat up in bed and fell back dead.

M. Reclus calculated that at least twenty grains of cocaine must have been injected, while the proper dose, suiting all intents and purposes, was two grains. Evidently the patient died from an overdose of cocaine.

POISONOUS PROPERTIES OF THYROID EXTRACT.

A communication has been made to the Société des Hôpitaux by M. Chantemesse respecting a case in which the thyroid extract, while useful up to a certain point, produced excessive vertigo and other inconvenient symptoms when pressed, together with elevated temperature and great restlessness, but these symptoms passed off in a little time.

◆

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, March 30th.

TISSUE JUICES AND THERAPEUTICS.

IN my last letter I referred to the experimental researches of Fürbringer on the subject, and am now in a position to give further details. The thyroid gland treatment in myxœdema in Hr. Fürbringer's hands showed a short but vigorous existence. The first who had transplanted thyroid tissue in the treatment of myxœdema or *cachexia strumipriva* was Kocher.

His experiments were commenced ten years ago. In all investigations both clinical and experimental it was shown that a specific action took place, wherever the transplanted lung thyroid gland continued to grow. In spite of the rarity of myxœdema publication increased rapidly. From England either considerable improvement or complete cures were reported. As regarded the method of administration, subcutaneous injection was soon introduced in place of transplantation. By and bye the attempt was naturally made to give the gland by the mouth. It was swallowed both raw and cooked, as powder, &c. It was found that the action was identical, however given. The common factors for improvement were diminution in the myxœdema, raising of the temperature, acceleration of the pulse, increase in the urine and in the excretion of nitrogenous constituents. The dull look of the patients disappeared, they became more talkative, lost their psychical depression, and even their intelligence returned. The investigation had uniformly showed that thyroid juice was, as regarded the system as a whole, a very important, yet indispensible substance. Zanda had made a remarkable experimental observation When he extirpated the spleens and thyroids of dogs at the same time, they did not become affected with myxœdema but only when he removed the thyroid alone. He concluded from this experiment that the spleen poisoned the blood and that the poison was removed by the action of the thyroid. One could contemplate the triumph of therapeutics with pride were not some degree of caution necessary with regard to it. He was not thinking of local troubles or failure of the treatment, but of the extremely dangerous state of cardiac weakness that came about as a consequence of the treatment—anæmia, stenocarditic condition, cases of sudden death (inquest in Edinburgh). Hoffman described a peculiar cachexia coming on in consequence of the injections more dangerous than the myxœdema itself.

As regarded the treatment of diabetes by pancreas juice, this was of more recent growth. Here also we have two little experimental foundation of Thiroloix, who treated two dogs with pancreatic juice, and observed that, generally speaking, they did not become glycosuric when the pancreas was removed. The reports of authors differed materially. During the last few days he had begun the pancreatic treatment in two cases of diabetes, so far without any marked result. Renvors also had treated a case of diabetes in the same way.

The incorporation of nerve substance ("cerebrin") he could only designate along with Leyden as a therapeutic wonder. The chief experimenters were Babes, in Bucharest, and Paul, in Paris. The brain and spinal cord of rabbits, sheep, and oxen were employed, and cases of tabes, neurasthenics, &c., were treated, Negel found with no perceptible action.

With regard to the notorious Gatschkowski's "vitaline" that caused the death of a Russian dignitary, the speaker had in vain tried to satisfy himself as to its composition, but he had ascertained from pharmacological report that it contained borax, glycerine, testicular extract, some cerebral and vegetable alkaloids. Since the cerebrin publication a gentleman of his acquaintance had ceased to eat calves brains as he feared a transmission of the properties of the calf's organ of mind might take place. Cardine was formed from eight months' maceration of the heart of the calf. It naturally works wonders in all possible diseases (Onimus Hammond).

Nephrine had recently been used by Brown-Séquard, who was of opinion that the internal disturbed secretion was restored by injection of it. More recently still hepatine and musculine had been brought forward by Brown-Séquard. He recommended that his extracts should be sprayed through the larynx into the lungs.

In conclusion, he might say that upon the whole we had to deal with recommendations, the inner scientific nucleus of which we must respect. This was especially the case as regarded thyroid therapeutics, and also Pöhl's spermine, other organic extracts might wander back into the laboratories to which they belonged. The principal thing was clinical determination, and this was enormously difficult. Here the mysterious force of suggestion might deceive even the critical glance. At the same time he could not yet agree with those who put down all treatment by organic juice as a new phase of suggestive therapeutics. We must move untiringly onwards in order by clinical observation to substitute the actual in place of the questionable.

◆

Austria.

[From our own Correspondent.]

Vienna, March 30th.

At the meeting of the Gesellschaft der Aerzte, Hr. v. Hacker showed an elderly woman on whom he had performed a plastic operation for carcinoma two years ago. He had brought down a flap from the forehead, and the result was excellent.

Hr. Büdinger then gave an address,

Healing of the Ureter in the Bladder.

The speaker said that in suturing the ureter at operations there were two dangers—the tearing out of the suture and the formation of a stricture. The attempt had therefore been made to suture the ureter to the bladder, but experiments in this direction both in men and animals had not succeeded very well. The speaker had now employed Witzel's method of gastrostomy for the implantation of the ureter into the posterior wall of the bladder. The abdomens of dogs were opened, the bladder drawn forwards, the ureter drawn forwards, and cut through a few centimetres above its point of entrance into the bladder. The end was then inserted into a slit in the posterior bladder wall, whereupon its sheath was fixed to the muscular coat of the bladder and the peritoneum. Six weeks after the operation, which was well borne, the ureter was found firmly attached and completely pervious. After these attempts, the speaker proceeded to test the method in the case of ureteral fistula. He therefore made a fistula in the ureter of a dog, opened the abdomen afresh three weeks later, picked up the ureter, made a longitudinal incision into it, which he fixed to a similar incision in the bladder, and fixed it in position. A month afterwards the dog was killed: the ureter was found fixed to the bladder, and was easily permeable, the upper part was slightly dilated, and also the pelvis of the kidney to a slight extent. He thought this method of operation was applicable in the case of the human subject.

Hr. J. Schnitzler then showed a man who for two years and a half had had

A Chondroma of the Chest Wall

which reached upwards to the manubrium, on the right to the mid-sternum, on the left to above the nipple line, and downwards to the arch of the ribs, and which projected 5 cm. above the skin level. The growth proceeded from the ribs, passed through the intercostal space, and was attached to the pericardium. At the operation the pericardium had to be opened, so that the heart projected through an opening the size of the palm of the hand. The sutures to the pericardium tore out. For three weeks long the cardiac movements could be seen through the flaps, but by the flattening of the thorax the ribs had come so well together that a celluloid covering for the defect was no longer necessary.

Hr. Ewald then showed a woman suffering from

A Peculiar Bone Disease.

The patient, a woman, æt. 49, fell on her left elbow seventeen years ago, upon which pains came on in the left arm. Four months afterwards, the arm swelled and became red, with rigors and fever. The fever and pain gradually subsided, and an increase in the bone substance came on in places, and in 1886, after an injury, the patient had a swelling of the manubrium sterni that came on with fever, but gradually subsided. A later injury to the head was succeeded by a series of cerebral symptoms, with redness and swelling of the face. The hyperostosis of the arm was still present. The affection was not syphilitic, the cerebral symptoms were against the case being one of Paget's disease. It most resembled concheolini-ostitis, but there was no connecting link with this as it came on in youth.

Herren Obersteiner and Redlich then gave an address on

The Nature and Pathogenesis of Tabes Dorsalis.

They said that in incisions made along the posterior roots normally, the posterior root, at the point of entrance into the cord showed a noticeable narrowing or constriction. According to their observations, it was only in tabes that there was a meningitic process that led to inflammatory thickening of the pia mater, whereby the constricted part of the posterior root was still more compressed. The vessels lying there were atheromatous, thickened, and also contributed to the compression of the posterior root. The changes found were in unison with the known anatomical and clinical facts. We now understood much better the connection between tabes and syphilis. The latter, as was known, showed a tendency to wheal-like thickening of connective tissue and to disease of vessels, and thus to the identical changes found in tabes. The coincidence of atherosis and tabes was also more easily comprehended. The lancinating parts were explainable by pressure on sensory nerves. The results of anti-syphilitic treatment at a period when meningitis in the form of an exudation was present were explainable by the condition found. In the same way, we understood the partial results of nerve stretching, as by it, as Gussenbauer had shown, the stretching implicated the cord itself, and produced certain softening of the connective tissue.

◆

The Operating Theatres.

MIDDLESEX HOSPITAL.

Combined External and Internal Urethrotomy—Mr. **Pearce Gould** operated on a man, æt. 60, who for many years had suffered from urinary trouble culminating with an abscess in the perinæum; at the time of operation there was a tight unyielding stricture in the deep part of the urethra, and it was impossible to get any instrument into the bladder. Mr. Gould said he proposed to divide the stricture by Wheelhouse's method, then put in a catheter and sew up the urethral tissues over it, completing the operation by sewing up the muscles and fasciæ and finally the skin. He pointed out that what he was about to do was really combined external and internal urethrotomy, the advantages being:—1. That the patient goes out at the end of a fortnight instead of having to remain in the hospital at least two months, as would be the case with ordinary perineal section. 2. That the surgeon can be absolutely certain that all the stricture is divided. 3. The absence of hæmorrhage. He mentioned that he had practised this method only once before, and that it had answered admirably. A straight grooved staff having been passed down to the stricture, Mr. Gould cut down in the perinæum, divided the stricture, and got into the bladder, utilising first a probe and then a gorget; he then passed a full-sized gum elastic catheter through the penis into the bladder. After thoroughly irrigating the wound with an antiseptic solution he proceeded to sew up the tissues of the urethra over the catheter; he then brought together the muscles and fasciæ, and finally the external skin wound, making use, except for the skin, of a very convenient needle on a handle having the eye at the point but the edges being perfectly blunt. The catheter was tied in and dressings applied to the perinæum.

In "Operating Theatres" of last week's issue Mr. Pearce Gould was made to appear as if in favour of the patient's wrist being kept under her neck during excision of the breast; it should have been exactly the contrary, as Mr. Gould strongly disapproves of such a position.

Vaginal Hysterectomy.—Mr. **Bland Sutton** performed vaginal hysterectomy on a woman, æt. 46, suffering from cancer of the body of the uterus. The patient was the mother of several children, the youngest being five years of age. When she first came under observation, she complained of hæmorrhage from the vagina, and great pain in the loins. The bleeding had continued for six weeks, and up to this period her menstruation had been normal. The os was patulous and the wall of the cervical canal suspiciously hard. She was advised to rest absolutely in bed for two weeks. At the end of this period the hæmorrhage was worse. She was admitted into the hospital, and on examination under chloroform, the uterus was found slightly enlarged, and the cavity was somewhat dilated, the introduction of the sound being followed by free bleeding. The canal was then dilated with Hegar's dilators, and the body of the uterus was found to be filled with soft material which bled readily. This soft substance was detached with a blunt spoon, and the bleeding checked with water at 110° Fahr. On examining the matter removed from the uterus under the microscope, it was found to be characteristic of cancer of the body of the uterus, and as the case appeared very favourable for operation, the patient was advised to submit to hysterectomy. She was placed in the lithotomy position, and the external genitals and vagina douched with perchloride solution (1 in 1,000). (The parts had been previously treated in a similar manner three hours previously.) The bladder was detached from its relation with the cervix; the recto-vaginal pouch was then opened, leaving the uterus free in front and behind. The lateral connections were next dealt with in the following manner: The tissues of the lower part of the broad ligament were transfixed and securely tied with a silk ligature, first on the left, then on the right side, and the tissues cut through, care being taken to keep close to the cervix. The uterus was then drawn lower into the vagina, and the remaining segment of the left broad ligament transfixed with a double silk ligature, tied as in ovariotomy and cut through. The same manœuvre was carried out on the right side, and the uterus cut away. The ligatures were then loosely knitted together, the vagina carefully irrigated with plain water at 100° Fahr., and a strip of iodoform gauze laid in the vagina. There was very little blood lost throughout the operation. On section, a cancerous surface the size of a shilling was found at the junction of the cervical canal and uterine cavity. Mr. Sutton pointed out that the only method of diagnosing with certainty cancer of the body of the uterus consisted in dilating the canal, obtaining fragments of the growth and examining them microscopically. The method, he said, had been carried out in this case with gratifying results.

◆

The Dublin medical students appear not to have been reduced in temperature by the Easter holidays. They have addressed, as is quite proper, a separate memorial to the College of Physicians setting forth the grievances which were submitted to the College of Surgeons. They are also somewhat impatient and fretful, and are about to hold another indignation meeting because the Council of the College of Surgeons have not assembled (for the students' behoof in special haste in Easter week). These young gentlemen, it would appear, have yet to learn that they must take their turn with other people in the order of College business, and that their impetuosity, not to say bumptiousness, will not at all advance their cause. What they have to say ought to be said calmly and argumentatively, and considered in the same spirit, and newspaper bluster and stump agitation are quite out of place in the discussion of such matters.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 4, 1894.

THE STATE IDENTIFICATION OF CRIMINALS.

THE department of criminal police has been active of late, stimulated doubtless by the remarkable and startling perfection of the methods of criminal investigation and identification pursued in Paris. There the system of M. Bertillon is now firmly established, and has attracted considerable attention from many countries of the civilised world. Quite recently a blue-book has been published containing the report of a committee appointed by the Home Secretary to inquire into the best means of identifying habitual criminals. The lay press has from time to time made its lay readers more or less familiar in a general way with the Bertillon system; but this report as the result of personal investigation at the Prefecture of Police in Paris goes more fully into details, and examines the method there in vogue in a critical as well as complimentary spirit. The English system, especially in country districts, has been too much a system "by rule of thumb." The English police practice is described as widely varying in different police districts, and as being chiefly dependent on personal recognition by police or prison officials. Add to this the occasional aid of photography, and the routine practice of long, often irrelevant reports, and we have the gist of the matter, at least outside the great English cities. The feeling seems to be growing in the Criminal Department of the State, that while this may do well enough for local residential criminals, it will not do for the travelling fraternity whose head-quarters are in large centres, and for the international criminals who visit our shores and find an asylum in the Metropolis. Accordingly, the committee already referred to has made an exhaustive inquiry, going even beyond the mere question of identification, and the report is very interesting and suggestive. They examined critically the Bertillon method and the system recommended by Mr. Francis Galton. The principle of the former method consists in taking a record of each prisoner, comprising certain measurements which depend mainly on the lengths of bony structures in the body. These are tabulated on cards, so classified that the man and his card can be identified the one with the other, without his name being known, or in spite of any number of *aliases*. The following are regarded as perhaps the most important measurements:—(1) Antero-posterior and lateral cranial measurements. (2) The length of the left middle finger. (3) Of the left forearm; and (4) Of the left foot. These are regarded as the most constant in each individual and the most widely varying in different individuals. Galton's system is to work by taking impressions from the bulbs below the tips of fingers and thumbs. Further, by the use of printer's ink he takes impressions on cardboard from the palms of the hands. As the result of a long investigation in this direction Mr. Galton has assured himself that the chance of two finger prints being identical is less than one in sixty-four thousand millions. In reference to this the Committee say: "We are clearly of opinion that for the purpose of proving identity, the finger prints examined and compared by an expert furnish a method far more certain than any other." For the purpose of classification, Mr. Galton recognises three types of finger print impressions, viz., "arches," "loops," and "whorls." These by a series of formula he further elaborates, and thus a personal distinction is observed in the case of each individual. The Committee are not yet satisfied that this system can be followed *ad libitum*, though the plan has worked very well up to 2,500. Briefly, the Committee's finding may be summed up in this, that Bertillon's and Galton's methods should be combined to supplement and strengthen the old method, that the latter should not be discarded for the present, but that reports should be abbreviated. There must certainly be a strengthening of the hands of justice by the inauguration of such a system, and the only regret we would express is that it is not an international one. London is an international centre for revolutionary criminals, the most dangerous of all classes, and such terrible catastrophes as have recently occurred in Paris and threatened London itself should be a warning not only to this country, but to the civilised world.

◆

EYE DISEASES IN GENERAL PRACTICE.

The question of how much knowledge of special practice is necessary for the general practitioner can by no means be readily answered. Its adequate discussion would require far more space than that contained within the limits of an ordinary journalistic article. The subject, indeed, might be brought forward with considerable advantage at one of the larger medical societies, perhaps in the form of an inaugural address. In some form or other, the growth of the specialities presents an ever present difficulty to those who are responsible for the control of medical education. As each year adds to the sum total of our special knowledge, it obviously becomes more difficult for any ordinary man to retain anything like a comprehensive grasp of the principles of medical progress. Nor is the proposition less obvious that it is impossible for any single individual to acquire a full, thorough and adequate knowledge of more than one or two specialities. Yet the men of light and leading are for ever insisting that this or that highly specialised branch of learning should be added to the curriculum of the medical student. At one time it is suggested that candidates should show proficiency in mental diseases, in gynæcology, in fevers, or in diseases of the throat. At another time it is proposed that they shall be examined in diseases of the skin. Indeed, that proposition was brought forward at the last meeting of the British Medical Association. Happily for future generations of students the matter was allowed to drop, but not before several speakers had pointed out that leading dermatologists themselves were not agreed upon the diagnosis and nomenclature of several well-recognised skin affections. A difficulty of a similar sort became apparent a short while since at the Ophthalmological Society, where members were not at all in accord as to what constituted so common a malady as school ophthalmia. But while the general practitioner is not concerned with the determination of doubtful points in ophthalmic practice, yet his general education cannot be considered as complete unless it embraces a thorough acquaintance with a number of ordinary eye conditions. He must know, for instance, the symptoms of asthenopia which are due to refractive errors. He will not attempt to correct those visual errors when present, nor will he allow his patient to trust himself for that purpose to the arrogant pretensions of a self-educated optician, or indeed to any one but an oculist skilled in retinoscopy. Then the practitioner must learn to recognise acute glaucoma, no very difficult matter, if he accustom himself to examine the tension of normal eyes. At some period or other of his professional career he is certain to come across a case of the kind, where promptness of action is absolutely essential to successful treatment. It is hardly necessary to add that he should be familiar with the ordinary conjunctival affections, such as trachoma, phlyctenular disorders, and the various forms of acute ophthalmia. Among the last-mentioned ophthalmia neonatorum and gonorrhœal ophthalmia will test his resources to the uttermost. The intelligent treatment of the common diseases of the cornea falls equally within the province of the general practitioner. To this list other maladies, such as blepharitis, syphilitic iritis, and so on, might be added; but enough has been said to mark out broadly the ground that is common to specialists and to the profession generally. Where to draw the line is another and less easy matter to define, and much will depend on the actual knowledge of the non-specialist. The more he knows the less likely he is to do harm to his patient, for he will recognise his own helplessness in any particular case. Another point is that practical special skill is often more necessary to the country practitioner than to his urban brethren. The one has to rely in urgent cases upon his own unaided resources, whereas the other has always hospitals and specialists conveniently at hand. It is an admitted truism to say that the general practitioner will find it to the advantage not only of his patients, but of his own reputation, if he master a few general principles in the diagnosis and treatment of eye diseases. In many cases, as already hinted, so great is the accumulation of special knowledge in this branch that he will be able to do little more than realise his own ignorance. Then he will call in the specialist to lay down definite lines of treatment. Nor is he at all likely to interfere with matters outside his skill. To a conscientious and well-educated practitioner the limitations of his interference are no less clearly defined than the field of his capabilities, which are unhesitatingly brought into play when demanded by the interests of his patients.

◆

THE DUBLIN WINTER CONJOINT EXAMINATIONS.

The return by the Committee of Management of the two Colleges for the January examinations shows a slight improvement on last year, both in the numbers of candidates and in their educational quality, if the rejection percentages are to be taken as a test. Thirty-eight candidates came up for the Final, against 33 this time last year, and of these, 52·60 per cent. were rejected, against 57·60 last year. It is satisfactory to note that the method of marking which was introduced at the instance of the College of Physicians a few years ago has been got rid of, and the former system of marking by numbers has been restored. Under the system now abandoned a complicated code of signs was adopted. If a candidate answered in any subject barely up to past standard, he got a P; if his answering was better than a bare pass, he got a P plus 1, or P plus 2, or P plus 3, as the case might be. If, on the contrary, the candidate's answering fell slightly below pass standard, he got a R. U., which meant that he was to be rejected unless he showed particular merit in other subjects, and if the answering was specially bad in any subject, he got a R. in that subject, which meant that he should be rejected in it, no matter how well he might answer in others. The object of this system, against which nothing can be said but that it was complicated, was to allow some elasticity in the examination, so that the candidate, while liable to peremptory rejection if grossly ignorant of a subject, should be allowed the credit if he appeared to be a "good all-round man." The Medical Council Visitors, however, did not approve of this compensatory arrangement, and they maintained that the candidate should stand or fall by the arithmetical test of a fixed and immutable mark, so that, if a student displayed the extremest erudition and practical capacity in every subject save, say for instance, forensic medicine, he should in no wise be allowed to get his diploma. In this view the General Medical Council is, we think, all wrong. It would be wrong even if examiners were immaculate (which they are not), because by the rule of an immutable mark, the insignificant subjects, such as mental disease, vaccination, and forensic medicine, are raised to a position of as much influence in the student's passing as anatomy, medicine, surgery or midwifery, which are, so to speak, the life-blood of his future practice. The Committtee of Management for these Conjoint Examinations has, in our opinion, made this mistake of the General Medical Council much worse by decreeing that in future, under the numerical marking system, pass "by vote" shall be impossible. The pass "by vote" was the means by which the discretion of the entire Court was enabled to over-rule the incapacity or faddishness of any one examiner, and to pass a man, notwithstanding the refusal of that examiner to give him a pass mark. It should be understood that, under the "vote" system, no danger could arise of the passing of a man grossly ignorant of a subject, because it was always open to the examiner to give a 0, which absolutely debarred the candidate from the benefit of a "vote," and in any case, the full Court almost never passed a man in face of the persistent objection of any one examiner. In order that a perfect interchange of opinion on the merits of condidates should be arrived at, a conference of the entire Court, without exception, assembled after each examination, when the marks of the candidates were read out *seriatim*, and a mutual decision as to "pass or pluck" come to, often after considerable pleading. If, as the Committee of Management has decreed, the "pass or pluck" is to be determined in future by a mathematical formula, it is difficult to understand what advantage can be gained by the assembly of a conference, and equally difficult to understand what advantage will accrue to any candidate from acquiring a higher standard than is essential for a bare pass.

◆

Notes on Current Topics.

The Earnings of a Liverpool Quack.

When the fact of the miserable incomes in many cases of fully qualified and highly competent medical men is taken into account, the announcement that a Liverpool quack has for some time been able to wheedle out of the British public an income of between £3,000 and £4,000 a year is suggestive of anything but pleasurable reflections. Fortunately, however, the career of the quack in question has come to an untimely termination, inasmuch as he has been convicted of fraud and sentenced to penal servitude for five years—the maximum penalty. As is invariably the case with this class of swindlers, he resorted largely to advertising, and adopted the title of "Professor," despite the fact that he had previously followed the somewhat unpretending occupation of a bill-poster. His line of practice was chiefly that of the treatment of the sexual functions of the male sex, a most fertile arena for fraud and deception. His "patients," according to the report of the trial, included merchants, office boys, college boys, and clergymen, all of whom probably applied to him while labouring under the false impression that there was something seriously at fault with their generative functions. The ignorance among boys and youths in respect to the normal changes which ensue in the generative apparatus at the time of puberty is natural enough, but there is hardly any excuse for men of maturer age, clergymen and others, for the wholesale manner in which they are accustomed to throw themselves into the hands of unprincipled quacks on account of imaginary sexual derangements. We cannot too strongly urge upon all those who allow their fears to overcome their discretion in these matters to proceed at once to make their confidant of a medical practitioner, whose advice would in the majority of cases soon have the effect of restoring their peace of mind.

Mrs. Besant as a Ganges Bather.

The Editor of the *Theosophist* has written a letter to the public newspapers defining Mrs. Besant's position with regard to latterday Hinduism. From his statements it appears that the lady in question has openly and often declared herself a Hindu of the Aryan, and not at all of the corrupt modern, type. Into the subtle eclectic wilds of "*Theosophia*," peopled with its Vedas and Ufanishads, and other strange gods, it is impossible for the average mortal to follow. There is another and plainer point, however, raised in the letter above alluded to. From the editor's account we gather that during his absence some enemy crept into his office and sent to press an untrue statement to the effect that Mrs. Besant, "as becomes a devout Hindu, bathed daily in the sacred Ganges at Allahabad during the Kumbha Mela." We are glad to hear, however, that Mrs. Besant did not go near the water, nor bathe in the sacred stream even once, whether as Hindu or otherwise. This is reassuring, for one could hardly wish his greatest foe to run so terrible a risk as that involved in bathing in the Ganges, more especially about the time of the festivals. Now that the position of cholera as a water-borne disease is firmly established, these great meetings of pilgrims can be looked upon as little more than huge artificial centres of epidemic infection. The excreta of many thousands of infected persons reaches the river, the water of which is drunk by the natives as a part of their ceremonial rites. The editor describes graphically how he, "together with Mrs. Besant and other friends, watched the vast multitude (numbering a million and upwards) bathing, making their puja, and moving about in dense masses." It is time the authorities interfered with these religious gatherings in the interests of the nation whose government they have undertaken.

Anti-Cruelty and Anti-Vivisection.

The recent decision of the London magistrate upon the charges of cruelty brought against the Aquarium lion-tamer affords some suggestive food for reflection. The fact appears to have been established that the lions were cruelly treated during their performances, but the summons was dismissed upon other grounds. Without hearing evidence for the defence, the magistrate stopped the case on the ground that lions were not "domesticated animals," to which alone the statute applied. He doubted whether previous convictions for torturing captured linnets could be upheld under a proper reading of the Acts. Possibly, or probably, the next step of the S.P.C.A. will be to agitate for an enlargement of the scope of the Act so as to include wild animals. This logical extension of a sound principle cannot fail to meet with the general approval of humane men. It would, however, plunge the Society into a perfect abyss of aggressive work, for every fish, bird, and beast which is at any time chased or captured would be entitled to its protection. As matters stand, any brutal tamer is permitted to thrash his lions to death's door without let or hindrance, in order that he may pander to a low and vulgar craving for sensational amusement. At another time, a barbarous foxhunter, called by courtesy a gentleman, may cruelly ill-treat his horse on the hunting field, and escape with a trifling fine. On the other hand, the experimental physiologist, who has in view the highest ends open to humanity, finds himself hedged in with harassing and insulting laws, while he is held up to public opprobrium as a past-master in heartless cruelty to animals. Still, there is hope for the future now that the societies have ventured to beard the menagerie keeper and the still more powerful sportsman.

A Peculiar Madness.

The differentiation of the various forms of insanity grows apace, and the old cry of excessive terminology and elaborate classification is of no account. The latest form of madness is reported from the Asylum of Sainte-Anne, in Paris. The patient so affected is regarded as entirely sane in all respects but two. One, an incontrollable impulse to bark like a dog, and to otherwise imitate "all the modulations of the canine voice." The other, a passion for the number "three." The barking mania, we take it, is not quite exceptional, for it is not unusual for epileptics and idiots to mimic dog-barks, and the passion for the number three is by no means uncommon among the sane. Dr. Oliver Wendell Holmes observed how frequently men think in triads. The fact is that few men have not some peculiarity of mental habit known only to themselves, and the tendency to nominate everything of the kind a monomania or madness is absurd. It will have this effect by-and-bye, that madness will not be regarded as so grave an affliction as in days gone by.

Fragile Paraffin Lamps.

The public has long been painfully familiar with the danger attending the use of paraffin lamps in which the chamber is made of glass or other fragile material. Statistics show a large annual destruction of property and of life directly due to the breaking of such lamps. Last week the attention of the Clerkenwell Vestry was drawn to an occurrence of the kind in their district, where in one room, father, mother, and three children lost their lives by the upsetting of a paraffin lamp. At this meeting it was resolved to memorialise the Home Secretary with a view of having lamp reservoirs made of non-fragile material. This is a more practical step than the abstract rider which is commonly appended to the verdict by coroners' juries in similar cases. It cannot be too clearly realised that nothing short of legislative prohibition is likely to stay the hand of the manufacture of these dangerous articles. Glass is a cheap and handy material for the purpose, and is certain to be used regardless of its remote risks so long as permitted by law. There can be no doubt that to prohibit the use of fragile materials in the body of paraffin lamps would cause a revolution in the lamp industry. On the other hand, it is equally evident that nothing short of drastic legislation will suffice to deal with this ever-present cause of preventable mortality. Apart from the question of glass receptacles, every householder should know that the wick ought to be enclosed in a metal tube dipped deep into the oil, so as to prevent the possibility of lighted wick getting into the chamber. Each wick, in addition, should be provided with an extinguisher of approved pattern.

The Volunteer Medical Staff Corps at Netley.

The members of the Volunteer Medical Staff Corps who attended the Easter training at Netley may be congratulated on having had an exceptionally good and pleasant experience. About 200 men of all ranks were present under the command of Surgeon-Col. Norton. The weather was simply perfect, and nearly the whole of the time at the disposal of the corps was passed in various kinds of drill in the open. This highly important exercise was directly due to the action of the P.M.O., who was good enough to reduce the attendances of the men in the wards to a minimum. The actual work included military bandaging, bearer, company, stretcher, waggon and other drills, as well as the valuable and novel experience of embarking and transporting wounded men in boats. Easter Monday from seven to one was occupied by field exercises such as would be carried out in actual warfare. The detachment was in charge of Colonel Norton, Surgeons-Capt. Raw, Matthews, Adjutant Hayes and Quartermaster Captain Robinson. It was housed in wards of the hospital, where the men were most comfortably quartered. Commissariat arrangements were exemplified by the kind help of the Quartermaster of the Netley medical department. At the close of the training the P.M.O. expressed his satisfaction with the military bearing and thoroughness which had characterised the visit of the V.M.S.C. to the camp.

The Reorganisation of the Army Medical Control.

A recent number of the *Broad Arrow* contains a succinct, business-like, and reasonable epitome of the faults of the existing system of Army medical organisation, and the changes essential to make it more efficient. The author is manifestly conversant with his subject, and has the capacity to touch with a point the weaknesses of the Service control. We regret that we cannot produce the article, nor even give an exhaustive summary of it. The author holds that the central flaw in the system is centralisation of petty work in the Director-General's Office in London, and upon the D.G. himself, who is occupied with frippery details which ought to be dealt with by subordinate officers, leaving the D.G. free for the general direction of his department and for higher official functions. Every argument put forward in this *Broad Arrow* article commends itself to the medical mind as forcible and sensible, and we wish it could be read far and wide not only by doctors but by the public, and still more by the "military advisers" of the War Secretary, to whose jealousy is due the non-realisation of the desired reforms.

Mr. Watts and the College of Physicians.

Under the not strikingly appropriate introduction "ubi tres medici ibi duo athei," one of the morning newspapers discusses the recent decision of the Royal College of Physicians with regard to the portrait of their late President. It appears that Mr. Watts offered to present the Council with a replica of a likeness of Sir Andrew Clark taken shortly before his death. This offer, however, was declined by the College authorities, who have commissioned Mr. Lehmann to paint a portrait for their collection. Without entering into the comparative merits of the artists, or into the relative value of *ante* or *post mortem* portraits, it may be confidently assumed that the Council did not arrive at its conclusion without careful consideration of the circumstances of the case, otherwise the action of the Council in refusing so magnificent an offer would be inexplicable.

The Use of Ambulances in Mines.

The difficulty of carrying injured men through narrow and uneven passages in mines has often been recognised. But a special form of ambulance has now been designed by which it is held that the difficulty in question is largely overcome. The invention is due to a Belgian medical man, Dr. Paul Troisfontaines, and consists of a sort of hurdle or litter, made of hoops, placed parallel and joined by a fabric of cord or mat, somewhat like a hammock, thus giving, when required, rigidity in one direction and flexibility in the other. The injured man is laid in the litter with his legs extended and his arms at the side of his body; the upper part of the litter is then folded over and secured by three or four straps. The contrivance seems simplicity itself, and is well worthy of the attention of colliery managers in this country.

Death of One of the Pioneers of the Volunteer Movement.

The Volunteer movement was first promulgated by two medical men—Dr. Pycroft, then living at Kenton, a village near Exeter, and Dr. Bucknill, the present Commissioner in Lunacy. It originated out of a dinner given at Dr. Bucknill's house, in the year 1852, and the idea was first made public in a letter addressed to the *Exeter Gazette*. The scheme was then elaborated and submitted to the Government of the day, by whom it was substantially endorsed. The death has just been announced of one of the three who took part in what may now, we suppose, be called that historical dinner party—namely, Dr. Pycroft. In an appreciative notice of his life-work our contemporary the *Devon and Exeter Gazette* calls attention to the fact that he has passed away without having received any public recognition of his services in connection with the promotion of one of the most successful national movements which has ever been promulgated in this country. Dr. Pycroft, as one of the authors of the movement which has been of such value to England, and has excited the admiration of the world, was last week "carried to his resting place on the slope of the Haldon Hills, which were the first to ring with the report of the rifles of the Volunteers." Surely, even now, it is not too late to make some amends for the neglect which has been shown one of the fathers of the Volunteer movement. Cannot something be done to perpetuate his memory in consideration of the vigorous part he played in promoting the success of his offspring? But while Dr. Pycroft is dead and beyond the reach of mundane rewards, what is to be said of Dr. Bucknill, who, we believe, is still also unrequited for his share in the promotion of the citizen army?

Stimulants for Paupers.

The Liskeard Board of Guardians has made a new departure. It has appointed a medical officer, but imposed the condition that all alcoholic liquors should be regarded as medicines and supplied by a doctor gratuitously under his contract. We apprehend that the Local Government Board will have something to say on the subject, for, if alcohol is to be regarded as a medicine, there seems to be no sufficient reason why beef-tea and eggs should not be included in the same category.

The death in London, on Good Friday last, of Dr. M. L. Brown has created a vacancy on the staff of the Exeter Dispensary. For this post we hear that Dr. Russell Coombe is now a candidate. Dr. Coombe is the author of a useful little epitome of the British Pharmacopœia, and some years ago was House Surgeon at the Devon and Exeter Hospital. Moreover, as a Cambridge Graduate and a Fellow of the College of Surgeons, England, he has undeniably strong claims to the favourable consideration of the Governors.

Mr. Heuston, Surgeon to the Adelaide Hospital, Dublin, has been appointed Consulting Surgeon to the Cripples' Home, Bray, *vice* Mr. J. K. Barton, deceased.

The Administration of Lunatic Asylums.

It will be recollected that, three years ago, we resisted with all our influence, but in vain, the proposal of the Lunacy Authorities for Ireland to clear the visiting physicians out of the way of the superintendents, and to substitute for them junior assistants who would be well under the thumb of the residents. If anyone seeks justification for our resistance to this proposal, let him read the letters of disgusted English assistants published within the last few weeks in a contemporary:—"One who has held such an appointment solemnly warns 'any young medical man, unless physically incapacitated from practising his profession in any other way, against entering upon asylum life.' He found that he had no status whatever, and that he was liable to be held responsible for any treatment of patients or mismanagement of his wards, even when acting solely under his chief's orders." Another correspondent says that radical changes are required before the study of lunacy will attract men of real ability, promote the study of psychology, or advance the position of asylum medical officers; and he suggests that "superintendents should be chosen, not, as now, because they are good farm stewards and administrators; and that assistant medical officers should be selected, not because they have high cricket averages, play a good game of whist, or have a baritone or tenor voice." The picture here drawn of the English Lunacy system represents that which Irish Lunacy administrators were adjured to bow down to and worship, and when unbelievers objected to a subservient boy being put in the place of a responsible medical officer, they were told that they were behind the time, and did not understand the methods of modern psychology. Emphatically we retain the opinion that the extinction of the visiting physicians in Ireland in order to complete the despotism and the irresponsibility of the resident medical superintendents was a discreditable job, and fraught with disaster for the Irish Lunacy system not less than for the unhappy patient, one of whose safeguards was by this means withdrawn. The visiting physicians who sold their birthright for the mess of Dublin Castle pottage and assented to the extinction of their office because they were secured a continuance of their salaries for life deserve no sympathy in the matter. The public and the pauper lunatic are the persons who have suffered.

Medical Practitioners and their Bonds with Assistants.

A small detail which is not generally known in respect to the drawing up of the usual bond preventing an assistant to a practitioner from starting practice in a neighbourhood in competition with his principal is well worthy of notice. The point in question relates to the sum recoverable in the event of the bond being broken. Usually, a large sum is mentioned, for example, £100, £200, or even more. But therein comes the mistake. The amount to be claimed under the agreement should be under £50, for the following reasons;—Supposing the assistant takes it into his head to leave his principal for the purpose of starting a practice in opposition, the principal may instruct his solicitor to take proceedings, but any such proceedings could only be heard in the law courts if the sum mentioned under the bond was *over* £50. The result of this would be that months would probably elapse before the law would be able to reach the assistant: whereas, when the sum is below that of £50, proceedings could be taken at once in the district county court, a method of procedure which would be calculated seriously to interfere with the assistant's prospects. A case in which an assistant defied the bond, and commenced in the same street to compete with his former principal, has just been brought under our notice; in this instance the penalty under the bond was £100, but the assistant was good enough to inform his principal that the agreement was of no more value than waste paper, owing to the time which would have to elapse before proceedings could be taken.

The Chelsea Hospital for Women.

The position of affairs in regard to the dispute between the Chelsea Hospital for Women and the Medical Officer of Health for Chelsea appears to be one of determination on both sides to fight to the bitter end. The Vestry, it may be observed, have thoroughly espoused the cause of their Medical Officer and are prepared to undertake his defence in the event of proceedings for libel being commenced against him by the hospital staff. Dr. Parkes, however, has declined legal assistance from his Vestry, and has intimated that he will fight his battle unaided by ratepayers' money, believing that this course will leave him unfettered in instructing his own legal advisers should any action be taken. Meanwhile a committee of investigation has been appointed by the hospital authorities for the purpose of dealing with the allegations which have been made against the staff. We trust that the inquiry will be an exhaustive one, and that it will include the mortality statistics of the hospital for a period of years, an essential detail, as we pointed out a fortnight ago. Moreover, it must be clear that the past resident medical officers of the institution should be given an opportunity of tendering their evidence. We understand that there are three or four in practice in London at the present time, so that there would be no difficulty in calling upon them to say what their experience had been at the hospital during their term of office.

The Crusade against the Quacks.

Several energetic journals, notably *Hygiene* and *Science Siftings*, are doing yeoman service in exposing the fraudulent pretensions put forth by the vendors of this or that worthless nostrum. Their crusade is worthy of general support, for it is undertaken in defence of the public against the tricks of irresponsible quacks, whose sheet-anchors are aloes, advertisements, and lying assertions. It is surprising how silently the pretentious patent medicine man submits to the editorial lash. Whole broadsides of sarcasm and scathing comment directed against his wares are, at best, responded to by a lawyer's letter and a half-hearted threat of legal proceedings. There is nothing in the whole armoury of modern science that can silence the patent medicine vendor more effectually than the report of a chemical analyst. Some day, let us hope, an enlightened Government will wake up to the fact that it is shirking its duties in the protection of Her Majesty's lieges against this class of fraud by selling them for a paltry mess of pottage. A short while since a correspondent wrote to us making the suggestion that medical men would do well to place in their waiting-rooms a few copies of the journals that expose the quack medicine frauds. With that recommendation we heartily agree.

Bacterial Husbandry.

The correspondent of a morning contemporary has furnished a satirical and amusing skit on the Hygiene Department of the International Exhibition at Rome. He speaks of it as a sort of glorified Parkes' Museum for the promotion of a sound mind in a sound body, which the doctors have really no interest in promoting, "though it would never do to tell them so." "If," the correspondent observes, "we led the perfect sanitary life suggested we should seldom have occasion for their services. While disease still lingers among us, however, their professional enthusiasm for hygiene is of the highest utility; no doubt some of them—from Germany, of course—have carried this sentiment so far as to exhibit a bacteria farm, duly filled with cots and cribs in which the germs are reared. It is an odd kind of husbandry. A bacteria shepherd would be a novelty after the more conventional type. Does he pipe to his little flock? Professor Bacelli, chief among the many distinguished members of the syndic present at the opening ceremony, was the recipient of a poem composed in honour of the Congress, and did the shepherd to perfection, and piped in dulcet tones to his little flock, as we have since learned."

Cod-liver Oil.

If the *Chemist and Druggist* is to be believed, the present year will be one of the worst on record for the production of cod-liver oil. In an average year, about 60,000,000 of cod are caught, which yield about 22,000 barrels of oil, but there are years in which the take of fish is abnormally small, and there are years in which the amount of oil got from the livers is extraordinarily limited, and in this year it is stated that both factors exist, and that cod are both scarce and lean. The variations in the oiliness of cods' livers is extraordinary and inexplicable. For instance, in 1888 a hectolitre of good oil was got out of 250 livers, while in the present year 420 livers are required to produce the same amount, and in the worst year (1883) 1,000 livers were necessary. It has been gently suggested that the *Chemist and Druggist* has been "bearing" the cod oil market by these statements, but the opinions of that journal seem to be participated in by the dealers, for the oil which could be bought two months ago for 65s. a barrel sells now for 120s., and is estimated to reach 180s. before a couple of months hence have elapsed.

The Irish Poor-law Superannuation Bill.

The memorials prepared by the Irish Medical Association and duly signed by the members of the medical profession in each constituency have been forwarded to the local organisers throughout Ireland with an urgent request that they will, forthwith, adopt the means which they think best to present the memorial to their local M.P.'s. Meanwhile the assent of several of the Members whose names appeared on the Bill last year has been obtained, and steps are being taken to introduce it as soon as possible. It is to be hoped that the local organisers will not lose a moment in placing the memorial before their Parliamentary representatives in the most influential manner. Surely the Council of the Irish Medical Association has now done its part faithfully, and it is not too much to ask that those for whose benefit all this trouble and expense has been undertaken will stir themselves to make a good impression on their Parliamentary representatives.

The Association of Fellows of the Royal College of Surgeons, England.

An important meeting of the Committee of the Association of Fellows of the Royal College of Surgeons, England, was held on the 21st ult., Mr. Timothy Holmes, Vice-President, in the chair. The meeting was called for the purpose of discussing the action to be taken by the Committee in regard to the proposed new Society of Fellows, to which reference was made in our issue a fortnight since. It was unanimously resolved to draft a circular letter, setting forth the work which the Association had done in the interests of the Fellows during the past ten years, and pointing out that for various reasons the Committee was of opinion that no legitimate grounds could be assigned for the formation of another society of the kind. The circular letter will be in the hands of the Fellows to-day (Wednesday).

Plumber Registration.

The trades-union move promoted under cover of the Plumbers' Registration Bill is on the *tapis* again in the form of a Bill introduced by Mr. Lee Knowles, the inheritor of all the legislative fads which have been left derelict by Mr. Stansfeld, Mr. Picton, and the rest of the anti-everything party. Most likely, if this sort of thing goes on, we shall see a Bill in Parliament to erect a General Council of Corn-cutters with power to register duly diplomated chiropodists, and to punish with jail or fine any corn-cutter who unlawfully represents himself to be registered and diplomated. What a reduction to an absurdity the whole thing is!

Vaccination defaulters are very numerous in West Ham, consequently small-pox is rife in the district, and alarmingly on the increase. In order to stem the tide the Board of Guardians has decided to at once prosecute 3,000 for non-compliance with the Act.

The Sanitary Conference, Paris.

The Sanitary Conference has made good progress with its work. Practically the delegates have concluded their labours, for the documents embodying the decisions arrived at were signed by them at a final meeting on the 2nd inst. The British delegates have accepted the bulk of the conclusions, and with regard to the remainder of the latter certain details will have to be arranged before assent can be given.

Rai Bahadoor Bansi Lal Ram Rattan, of Mian Mir, India, has offered to construct an additional wing to the Lady Aitchison Hospital for Women at Lahore, which will bear the name of Lady Lansdowne, and he has further undertaken to make some alterations and additions to the hospital which are urgently needed. This act of native liberality is worthy of wide recognition.

We understand that the vacancy in the office of coroner for the North-Eastern District will not be filled up for some time yet, as the County Council have in contemplation the re-arrangement of the boundaries of that district, and also the Eastern. Until, therefore, that business is settled no official notification of the vacancy will be made.

Surgeon-General A. Smith, M.D., C.B., retired list Army Medical Department, has been appointed Honorary Physician to the Queen. This officer served in the Crimean, Jowaki, and Afghan campaigns, receiving the medal for each, and the C.B.-ship in addition for his services in the Afghan war.

◆

The Eleventh International Medical Congress at Rome.

[FROM OUR SPECIAL CORRESPONDENT.]

Rome, March 30th.

Rome, with its historical surroundings, its classical attractions, its proximity to some of the loveliest scenery in the world, has had the effect of a veritable loadstone in attracting medical men to the Eleventh International Medical Congress. In the matter of the presence of members and associates of the Congress, the record of all previous *réunions* of the kind will be far eclipsed. The total number is placed at 7,000, a huge gathering when the time of year is taken into consideration. There were not wanting some who predicted a small attendance at this Congress as soon as the postponement of the date originally fixed was announced. But fears of this sort have proved to be groundless, and those medical men privileged to take part in the meeting will return to their homes carrying away with them many a delightful reminiscence of their visit to Rome.

Favoured by the most splendid weather imaginable, the opening ceremony of the meeting took place on Thursday last. To give a detailed account of this is scarcely necessary, inasmuch as full reports of the same have already appeared in the daily press. But the sight was one impressive, grand, and brilliant, and not likely to be soon forgotten by those who were present. There was, of course, some confusion in the rush for seats, but this was a drawback inseparable from the enthusiasm, eagerness, and more or less excitement among a crowd of such overwhelming proportions as that which besieged the Theatre Costanzi.

The Sections.

The real business of the Congress began at three o'clock in the afternoon, when the various Sections assembled for the purpose of electing their officers and for the transaction of other routine business. The hours fixed for the meeting of the Sections throughout the week are 8 a.m. to 3 p.m.; how the foreign working members of the Congress will relish beginning the day at the early hour of eight in the morning remains to be seen. Perhaps, however, they will brace themselves up for the occasion, and eschew some of the festivities in order to avoid the contingency of failing to be in their places when duty calls them.

The General Meetings.

The time fixed for the general meetings is 4 p.m. On Friday Professor Virchow was the orator. He met with a great ovation. The subject of his address was "Morgagni and the Anatomic Thought."

The Organisation of the Congress.

Everywhere one hears approval expressed in the highest terms of the successful organisation of the Congress. To make arrangements on a scale sufficiently great to meet the requirements of a *réunion* numbering upwards of 7,000 members must have been in itself a task of stupendous proportions, but to have succeeded in winning universal approbation from those for whose benefit the arrangements were made is a matter regarding which the working officers of the Congress deserve to be heartily congratulated. One detail of the excellent organisation which prevails may be noted. The four official languages of the Congress are English, Italian, French, and German, and special delegates have been appointed to attend to the requirements of the members belonging to the various nations. For example, Dr. Prochet is the delegate for England and the English-speaking members, and he can be distinguished by a badge consisting of the coat of arms of Great Britain. Again, Professor La Torre, as the delegate for Russia, France, Turkey, and Egypt, bears a badge on which the arms of France and Russia are interwoven, and so on. Moreover, each delegate is charged with the distribution of the distinctive badges to the members of the Congress belonging to the nation of which he is delegate.

Arrangements for the Ladies.

The arrangements for the ladies attending the Congress have been carried out with the greatest harmony and success. The Committee of ladies, under the patronage of the Queen of Italy, is divided into groups of five, in each of which is included ladies who speak Italian, French, English, or German. Each group is on duty by turn, either to accompany the ladies of the Congress on visits to the various places of interest, or to entertain them at the central meeting hall. The Committee has, moreover, decided to hold a large *conversazione* in honour of the ladies of the Congress on the evening of the banquet of the Sections.

The Commemorative Medal.

The Commemorative Medal will form an interesting memento of this highly successful Congress. It is a replica of a coin of the time of Antoninus, and recalls the following fact: In the year 294 B.C. the pest was raging in Rome, and after having consulted the Sybilline books an ambassador was sent to Greece to fetch the serpent of Æsculapius at Epidaurus. The relief represents the god Tiber half out of the water, in the act of holding out his hand to receive the serpent on its arrival at the temple, which had been erected in honour of the Goddess of Health on the Tiberine Isle. The trireme which has brought the serpent is seen coming from under the "Pons Fabricius," now the bridge *Quattrocapi*.

En Route.

It is a great misfortune and national blemish that the Italians lingor so far behind their neighbours in expedition and accuracy. Travelling in their country is not the most enjoyable feat that could be undertaken. Theirs is a painful absence of method, notwithstanding the gigantic enterprise in sculpture and painting. Those who made the route a little more circuitous than usual arrived all with the one colour—dust indescribable. The English traveller has no idea of this painful experience. After passing the Alps the country is flat and fertile, the rails embedded with sand that rises in clouds in dry weather with the least movement. After passing Bologna the Apennines give a greater variety, but the tunnels are so badly ventilated that the traveller had to suffer from the soot, which is nearly as bad as the dust.

The Official Journal.

The official journal, which has hitherto been the property of private members, is this time sold by the "ragamuffins" through Rome for "deux sous"—nothing without the cash here. Fancy one imperfectly acquainted with Italian expression and mercenary proclivities higgling with a street arab to get the official knowledge that should be provided to members with the least trouble. Owing to little blemishes of this nature it is difficult to say who is present. Accidental observation may isolate a few, as at the opening ceremony on Thursday, when Sir Wm. McCormac replied for England, and Prof. Gardner and Prof. McEwen, of Glasgow, spoke. Prominent also was Virchow: the veteran at these gatherings who is still quite active, and replied for his country. Before the end is reached many of the foreign members will have left, as there is already a perceptible exodus. Probably the sights of ancient Rome will be more interesting and instructive.

These notes are necessarily fragmentary, and as, moreover, the postal arrangements are in a state of confusion, I must defer fuller details to next week.

◆

Special.

THE LATE LORD HANNEN.

It was in Norway that we met the late Lord (who was then Sir James) Hannen in 1885. He was travelling with one of his daughters, and had hurried off from England immediately after his Divorce Court duties had ceased. We were a party of three, and happened at the time to be the only English people staying in the hotel. The place was Sandé, a beautiful little hamlet some miles inland from Vadheim, a place of call for the steamers travelling up and down the Sogne Fiord. Somehow the year 1885 was distinguished for being one in which Norway seemed to be a special centre of attraction for many notable people. The Prince of Wales, for example, visited the country in that year; and at Vossevangen we came across the cariole boy who accompanied His Royal Highness from that place to Eide at the top of the Hardanger. Then Mr. Gladstone was another visitor, being the guest of the Brasseys on board the *Sunbeam*. In addition we heard of several Bishops, and among them the late Bishop of Durham, Lightfoot by name, who was accompanied by two of his chaplains, one of whom told us that they were in frequent peril of their lives owing to the habit their lord and master had of galloping down the hills the Norwegian ponies which he drove in the "stolkerries." The evening we spent in the hotel with Lord Hannen was one of the pleasantest of the trip. His was a most interesting personality. The dark expressive eyes which lighted up his strong, somewhat Napoleonic features, were such as to leave an impression on one's memory for a long time. He conversed freely on subjects connected with himself. Among other things he told us that he had been operated upon for stone in the bladder by a well-known London surgeon. After the operation he asked the surgeon what his chances of health and life were. The answer was that it entirely depended upon himself. "You are suffering from the uric acid diathesis" was the dictum of his adviser, "and if you choose to live as a vegetarian, some years of healthy life may still be in store for you." Lord Hannen at once accepted the verdict, and sentenced himself to play the part of a vegetarian for the rest of his natural life. He said that he began by engaging a cook who excelled in making porridge. This amylaceous dish became from that time forward the staple item of his breakfast. A year had passed since the operation when he told us these things, and he said the result of the vegetarian experiment had been that his health was completely restored, and that he never remembered feeling so well at any time in his life before. He appeared to have quite an affection for Norway and the Norwegian people, and regaled us with an interesting account of the literature of the country, a subject which could hardly be said to be one of which many persons in this country could claim to have an intimate acquaintance. His mode of locomotion about the country was in a four-wheeled wagonette, somewhat like a pony carriage on a large scale. The oddity of the conveyance was that a four-wheeled carriage at that time was one of the rarest sights in Norway. Naturally his "turn out," which included a pair of ponies, attracted a large amount of attention on the part of the populace. Lord Hannen did much work of a very arduous description after the time of his visit to Norway in 1885, and foremost among it all was certainly his presidency of the Parnell Commission, in connection with which his name will be emblazoned on the pages of history. But it was probably only from his strong determination to carry out the advice of his surgeon and become a vegetarian that his life was preserved for nine years after undergoing the operation of lithotrity, and that he was able to crown his life-work by accepting a post the onerous duties of which he discharged with such consummate tact and ability.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Proposed Arrangement between the Edinburgh Colleges.—We understand that the proposal made by the Royal College of Surgeons, Edinburgh, with regard to the participation of that College in the working of the Research Laboratory hitherto carried on solely by the Royal College of Physicians is much to the following effect. The two Colleges to share the expense of the Laboratory equally, with exactly equal rights. The Fellows of the College of Surgeons to have access to the library of the

Physicians, while they open their museum to Fellows of the other College in a similar manner. It is by no means certain if the proposal will be accepted in its entirety, but even if that part relating to the laboratory could be settled, the increased funds at the disposal of the Laboratory Committee would enable research work to be carried on with many more conveniences than at present.

Bequests to Medical Charities in Edinburgh and Glasgow.—The late Mr. William Gillespie, formerly of Glasgow, afterwards of Edinburgh, bequeathed £250 each to the three Glasgow Infirmaries, to the Edinburgh Infirmary, the Leith Hospital, the Edinburgh Hospital for Sick Children, and to several societies for the benefit of the sick poor.

Enlargement of the Edinburgh Royal Maternity Hospital.—The annual meeting of this institution was held last Friday, when, after the ordinary business, Lady Tweeddale laid the foundation stone of the new "Married Women's Pavilion," for which £4,000 has been raised largely by means of last year's fancy fair.

Edinburgh University.—The Winter Session is now closed and the different professional examinations progressing. The first professional for medical and science degrees began on the 26th ult. The Summer Session is to commence on Tuesday, May 1st. The Murchison prize in Clinical Medicine is awarded in London this year at the Royal College of Physicians on April 9th, while the Triennial Prize of the Edinburgh University London Club, of the value of 20 guineas, is also open for competition. It is confined to graduates of not more than two years' standing, and essays on any subject in medicine or surgery are to be sent to the Dean of the Faculty of Medicine before April 30th, 1894.

University of Glasgow.—At the next meeting of Council a motion is to be made for the founding of a Chair or Lectureship of Public Reading and Speaking in the Glasgow University. The Spring Graduation Ceremony, which is fixed for Friday, 13th April, promises this session to be a highly impressive function; for besides the capping, conferring of ordinary degrees, and distribution of the University prizes, the testimonial to Professor Edward Caird (Master of Balliol) will be presented. Although it is not yet decided what form the presentation will take, an illuminated address and a reading-lamp seem to be the alternatives, and no doubt many of his former "sons" will be in attendance at their *alma mater* to give a parting reception to the new Master of Balliol. In taking farewell of his class on the 29th inst. Professor Caird said that all he would ask from the students in Balliol College would be a continuance of the courtesy, attention, and sympathy which he had always received from the students in Glasgow.

◆

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (April 2nd) was devoted to two cases of acute intestinal obstruction caused by a constricting band in which recovery had followed surgical intervention. They were reported by Mr. H. P. Dean and Mr. Hutchinson, jun., on the one hand, and by Dr. Pasteur and Mr. Bland Sutton on the other. In the second case the symptoms of obstruction recurred nine months later, whereupon the patient was operated upon by Mr. Hutchinson with success. In the other case the patient was a young married woman in whom the constriction formed consequent upon an attack of perimetritis. Her recovery was interrupted by an attack of lobar pneumonia, which, however, did not appear to have any relationship to the abdominal trouble. Mr. Hutchinson raised the question of suturing the peritoneum separately in order to avoid the formation of adhesions to the scar (which existed in his case at the second operation), and also, by the more accurate coaptation of the planes, to prevent subsequent ventral hernia.

Mr. Lockwood contested the necessity for the triple row of sutures after incisions through the linea alba, though he appeared disposed to concede its desirability after incision in other regions. He insisted on the importance of early intervention in these cases, before the intestine had become distended in consequence of intestinal paralysis. He alluded to the passage of flatus after operation as a good sign.

Mr. Stephen Paget related two cases, one of enteritis with obstruction, and another of obstruction due to a constricting band, to illustrate the importance of obtaining a precise and accurate history from the patient in view of a correct diagnosis.

Mr. Clinton Dent said that though early intervention was important it was not the only factor concerned in the success of these interventions. Many of the factors concerned indeed were still involved in obscurity. He urged expedition in whatever they did, and deprecated any complication of suture or otherwise which would tend to prolong the operation. He regretted that publicity was not given to the unsuccessful cases, which, he said, were even more instructive than the successful ones.

Mr. Egerton Jennings related a case in which the symptoms returned on the tenth day after all the constricting bands had been divided, whereupon he thought it best to create an artificial anus, which was followed by recovery.

Mr. Bland Sutton objected to the triple rows of suture as tending to unnecessarily complicate the operation. He himself never had recourse to this procedure, and he declared that he had never seen any ill effects follow his practice of comprising all the tissue planes within his single row of sutures. The great points in his view were rapidity and dexterity of operation, and especially the avoidance of undue manipulation of the intestines, which he thought was responsible for much of the shock which often follows these operations.

Mr. Hutchinson stood to his gun in the matter of the separate suture of the peritoneum, which, he urged, protected the patient against many dangers, such as the formation of adhesions and ventral hernia, without entailing any serious prolongation of the operation.

◆

DEATH OF DR. BROWN-SEQUARD.

We regret to record the death of Dr. Brown-Séquard in Paris on the 31st ult. He was born at Port Louis, in the Island of Mauritius, in 1817, and came to Paris in 1838 to complete his medical studies, and took his Doctor's degree in 1840. He from that time occupied himself with researches in experimental physiology. In 1864 he went to America, and was appointed Professor of Physiology and of Nervous Diseases at Harvard University. He returned to France in 1869, and went again to America in 1873. He then founded at New York the *Archives of Scientific and Practical Medicine*. Having returned to Paris Dr. Brown-Séquard was, in 1878, chosen as Claude Bernard's successor as Professor of Experimental Medicine at the Collège de France. In 1886 he was elected member of the Académie des Sciences in place of Dr. Vulpian, named perpetual secretary. The Cross of the Legion of Honour was conferred on him in 1889. Dr. Brown-Séquard noted and explained his numerous researches in "Mémoires," which procured for him numerous prizes; among them were the Lacaze Prize in 1882, and the Biennial Prize of the Institut in 1885. Since 1889 his announcement that he had discovered the means of reinfusing youth into old decrepit persons by means of subcutaneous injections of testicular fluid, his reputation has somewhat declined.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

WHAT CONSTITUTES UNSOUNDNESS OF MIND?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—We should be glad of your permission to make a few criticisms upon the views and suggestions contained in Mr. Bowreman Jessett's letter, with this title, in your last issue. It would conduce to a clearer conception of these views if Mr. Jessett would state what he means by the term "climacteric mania." It is pretty clear that he does not mean insanity, The condition, however, is one outside physiological limits, for it is subsequently referred to as a "form of disease" which furthermore is "purely functional." We submit that the effect produced upon the reader's mind by such terminology is one of confusion. It is to be gathered from Mr. Jessett's observations that persons may suffer at the climacteric from a "temporary mania" (sufficient to justify their confinement in "hospitals" or "wings attached to existing asylums," and of such a nature as to demand "the utmost care and attention) without being insane. What is the proper designation for the mental state of such patients? Clearly there is a mental alienation in some form in these cases. They require "the utmost care and attention," therefore the alienation is not slight in degree. Neither can it be a mere temporary disturbance; for as far as we are aware there is nothing in climacteric insanity comparable to the short, sharp, maniacal states sometimes seen after a drinking bout. If, as seems evident, the case alluded to by Mr. Jessett showed undoubted mental alienation, then the statement that "a very large percentage recover completely" is inaccurate. The recovery rate given by Dr. Savage is 32 per cent. Statistics collected by the writers (to appear in the *Journal of Mental Science* of April this year) show it to be 35—40 per cent. Proceeding on the same assumption in regard to the mental states of these cases, we quite agree with Mr. Jessett that they require "the utmost care and attention," more especially when the suicidal proclivity at the climacteric period (illustrated in the case which forms the basis of Mr. Jessett's letter) is borne in mind. Proper care and attention can only be given, in our opinion, in an asylum, private or public, according to the case. But few patients can be treated at home, for economic reasons; and we may add that, in practice, it is found that the publicity attaching to home treatment is not much, if at all, less than that associated with asylum care. We do not think it will be feasible in practice to institute a half-way house between the home and the asylum, such as Mr. Jessett suggests; since there are, indeed, no half-way cases. The mental changes attendant upon the climacterium are either physiological or pathological (constituting insanity). If the change have gone beyond healthy limits, then the potentialities in the case are endless, the risk cannot be estimated; and the only prudent course is to place the patient in some institution where every means of meeting eventualities is at hand—namely, an asylum. As a matter of fact, the system of voluntary boarders in vogue at certain asylums was introduced to meet the necessities of the class of case for which Mr. Jessett pleads; certainly this system might with advantage be universally adopted. Mr. Jessett asks "how many persons suffering from temporary aberration of mind who have been placed into asylums have actually become insane from contact with hopelessly insane people as compared to those treated in homes or at home under proper care and supervision?" We believe all who have experience of asylums will agree that this "contact insanity" is in the highest degree uncommon, that practically it is a myth; a subject for the novelist rather than the physician. Space fails, or experience disproving this idea could be adduced. It would be more useful to institute inquiry as to the prospects of chronicity in cases from which asylum treatment has been withheld and which have been kept "at home under proper care and supervision."

We are, Sir, yours, &c.,
Edwin Goodall and Maurice Craig.
West Riding Asylum, Wakefield.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Having been much interested in the case of Dr. Sherrard, and having given evidence at the trial, I may be excused for adding a few words to the admirable letter of Mr. Jessett which appeared in your issue of this day under the above heading.

With everything he says with regard to the wrong that may possibly be afflicted on a woman during the time of, the menopause who is inflicted with temporary alienation by placing her under the odium of a lunacy certificate I quite agree. And I am convinced that had a verdict averse to Dr. Sherrard been obtained the result would have been most serious to our profession and disastrous to the class of patient for the retention of which, without certificate, he was proceeded against by the Commissioners.

I refer more particularly to those climacteric sufferers from hypochondriasis and melancholia by whom the borderland of insanity is touched. It may appear, at first sight, a simple matter to reply to the question "What constitutes unsoundness of mind?" and we may confine within comparatively narrow limits our definition of *non compos mentis* when we are dealing with such a legal matter as testamentary capacity, or even, though in a less degree, responsibility for criminal acts. Yet even here the law constantly finds itself in difficulty. for if current reports were accepted as true a very distinguished statesman might have had his will impeached on the ground of his disregard for his personal property, and certainly Dr. Maudsley, on whose views all the medical witnesses were cross-examined in the recent trial, by his own showing, (Responsibilities in Mental Diseases, International Series) would have "signed" for the prophet Jeremiah. The Commissioners undoubtedly would have regarded the "lamentations" of the latter as distinct evidence of lunacy, and have refused him the shelter of a medical "home."

A recent communication compelled me to peruse the particulars of some 500 cases of women who had consulted me for various uterine affections. Of these 270 suffered from symptoms indicative of functional disturbance of other organs than the womb. Of the 270, 71 were between the ages of 40 and 53; 29 complained of symptoms which could only be accounted for by the "change of life."

The mental disturbances I have noted were aggravated hysteria, insomnia, depression and melancholia, dementia, agorophobia, and neurasthenia; while some suffered from epilepsy, catalepsy, neuralgias, severe headaches with fulness in the head, loss of memory, and tinnitus aurium.

I cannot say what the exact proportion was of those thus suffering, who were in the climacteric period of life, but I do know that the greater number of those attacked by purely mental symptoms were women passing through this physiological process of involution of their womanhood. Of those so afflicted, two, to my knowledge, were certified for—the one became maniacal, and the other attempted suicide, with no stronger evidence of alienation than that characteristic taciturnity which so frequently distinguishes these cases. It is worthy of note, in passing, how common is the delusion of the commission of some unforgivable sin, especially to the husband or near relatives, in these cases. Also, there is a feature apt to be overlooked which increases the difficulty in determining the course to pursue, when we meet with vague threatenings or childish and silly mimicking of suicidal acts.

I have seen a patient under these circumstances who threatened to throw herself out of the window, with no more intention of doing it than I had. These threats are frequently the outcome of hysterical instability and effeminate cunning. We hardly should place such a one in a lunatic asylum.

I have had several cases of women with melancholia and delusions who have recovered, in the private houses of medical men, under careful supervision without certificates. No one denies the need for extreme care, constant watching, and judicious nursing, both in the intervals between the attacks of depression or exaltation, and during the paroxysms themselves. But if we are to deny to medical men, under the threat of a criminal prosecution, the privilege of taking these patients into their homes, we place the profession in that invidious position "between the devil and the deep sea." On the one hand, there is the fear of a patient committing suicide who has not that close supervision to be secured in the private medical house, and, on the other, there is the dread of the consequences of an expensive and possibly disastrous law suit should he be party to consigning her to an asylum.

I, for one, certainly feel that the interests of the public and the profession, as well as the safety and liberty of numbers of afflicted women, have been best protected by the verdict of the jury in the case of the Commissioners of Lunacy *versus* Sherrard.

I am, Sir, yours, &c.,
H. MACNAUGHTON-JONES.

MEDICAL ORTHOËPY.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—It would appear that among scientific men, such as medical societies in England are composed of, the names of such societies should be pronounced strictly according to the rules of the English language, at least by their respective members; but such is not always the case. I have been a member of the British Gynæcological Society since its foundation, and have attended a good number of its meetings, and I may say that I have never heard the name of that society pronounced there according to orthoëpical rules; although, perhaps, not one meeting takes place without the name being mentioned several times.

The word "gynæcology" is derived from two Greek words, *γυνή*, gen. *γυναικος*, woman, and *λογος*, discourse, the accent falling, in the combined word, upon the antepenultimate syllable. There is also a secondary accent on the first syllable of the word which shortens the vowel of that syllable. The letter "*g*" in words derived from the Greek and Latin languages has the sound of "*j*" when followed by the vowels *e*, *i* and *y*, as exemplified in the words *gentian*, *gigantic*, *gymnastic*, but is hard before the vowels *a*, *o*, *u*, and before a consonant as in *galactagogue*, *gland*, &c. In words of Saxon origin, the "*g*" is generally pronounced hard: *get*, *give*, *stringy*.

According to the foregoing rules, the first syllable of the word "gynæcology" should be pronounced as the word *gin*, and the principal accent placed on the antepenultimate syllable, being an enclitical accent, thus *gynæcology* and so *gynæcologist*. In the word "gynæcological" the principal accent is removed one syllable nearer the end, being a terminational accent and so, in all words of the English language terminating in *ical*, the principal accent falls upon the syllable which immediately precedes this terminal, not even excepting *cervical*, the "*i*" of which should be pronounced as in the word vertical. Words terminating in *ic* follow the same rule with a few exceptions, but the syllable immediately preceding the terminal *ic* is generally short when it receives the accent, thus "orthopædic" should not be pronounced "orthopeedic," nor "anæmic" "aneemic," nor should "hæmorrhage" be pronounced "heemorrhage," because the accent falling upon these syllables shortens their vowel.

The general way of pronouncing the word "gynæcology" by the Fellows of the Society is to sound the initial "*g*" hard, and nearly all of them pronounce the "*y*" long, as in the word "Guy."

I am, yours, &c.,
P. Z. HEBERT, M.D.

54 Berners Street, W.

◆

A PROBLEM: THE ENGLISH DEATH-RATE FROM HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—As your able journal has given much attention to the subject of hydrophobia, I venture to submit to you the following problem. I give you the English death-rate from hydrophobia from 1884, as obtained from the Registrar-General, as follows:—

	Deaths.		Deaths.
1884 ...	28	1889 ...	30
1885 ...	60	1890 ...	8
1886 ...	26	1891 ...	7
1887 ...	29	1892 ...	6
1888 ...	14		

Now I give you below, as far as I can gather, the number of English patients who have gone to the Pasteur Institute, Paris, for inoculation:—

1884 ...	0	1889 ...	39
1885 ...	2	1890 ...	56
1886 ...	88	1891 ...	42
1887 ...	23	1892 ...	26
1888 ...	63		

The figures for 1884 to 1888 are correct, as I obtained them from the letter of M. Pasteur to the Lord Mayor of London; the other figures have had to be collected from journals; for 1889 I could not find any reference in the *Brit. Med. Journal* or the *Lancet*, and I shall be glad of correction or of an official list.

The problem is, What connection is there between the Pasteur treatment and our English death-rate? If there is, perhaps you would point out what percentage of the patients would have contracted hydrophobia Were they all in danger?

We know that from 1847 to 1884 the English death-rate runs up and down as follows:—

	Dths.		Dths.		Dths.
1847	5	1860	3	1873	31
1848	7	1861	4	1874	61
1849	17	1862	1	1875	48
1850	13	1863	4	1876	73
1851	25	1864	12	1877	82
1852	7	1865	18	1878	50
1853	11	1866	36	1879	35
1854	16	1867	10	1880	28
1855	14	1868	7	1881	34
1856	5	1869	18	1882	28
1857	3	1870	31	1883	34
1858	2	1871	60	1884	28
1859	4	1872	39		

In these years we had no Pasteur Institute, no antirabic inoculation, but we have almost the same death-rates, in certain years a lower one.

During the last few years we have vigorously proceeded against rabid dogs, and we have boasted we have stamped out rabies. So we have, and, therefore, the death-rate has been lower. We have practically stamped out rabies in London.

The Pasteur advocates may say take the years 1889-92, and you have only 51 deaths, whereas in the years 1885-88 you have 140. The answer I have given above, "we have diminished the death-rate because we have almost abolished rabies in the dog."

In England we do not hear about rabid cats—they are Parisian luxuries.

One final point: How very few have gone to Paris in comparison with the prognostications of the English Hydrophobia Commissioners. The final words of the report are as follows:—

"There are examples sufficient to prove that by these or similar regulations hydrophobia would be in this country stamped out, or reduced to an amount very far less than has hitherto been known. If it be not thus reduced it may be deemed certain that a large number of persons will every year require the treatment of M. Pasteur. The average annual number of deaths from hydrophobia during the ten years ending 1885 was in all England 43, and in London alone 8·5. *If, as in the estimates used for judging the utility of that method of treatment, these numbers are taken as representing only 5 per cent. of the persons bitten, the preventive treatment will be required for 860 persons in all England, for 178 in London alone.* For it will not be possible to say which among the whole number bitten are not in danger of hydrophobia, and the methods of prevention by cautery, excision, or other treatment cannot be depended on."

During the years 1884 to 1892 the total number of deaths were 208, an average of 23. According to the calculations of the Hydrophobia Commissioners, we have to halve the number requiring treatment, for all England, 400; for London 80 alone, so that for the nine years 3,600 should have gone to Paris from all England, and 720 from London alone. You see the number that have gone for nine years is 339. I should be glad to know the exact number, and I give 50 more, so that we may say 389 patients have been to Paris since the introduction of the system. Had we had an institute in London we should probably have had our thousands annually inoculated on the probability that every person bitten by a dog was in danger.

These figures are interesting, and will be more so in the future when protective inoculation against hydrophobia will be discussed apart from personalities.

I am, Sir, yours, &c.,
B. Dubious, M.D.

◆

A GYNÆCOLOGICAL QUESTION RELATING TO THE HYMEN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The following cases are, I think, of interest as bearing on Dr. Macnaughton Jones's paper in the Medical Press of March 21st:—

Seven years ago I was consulted about Miss S., then æt. 17. She had never menstruated. She was suffering intense pain in uterine region, with a temperature of 102 deg. On examining abdomen a hard tumour was detected reaching almost to umbilicus, and there was a history given of recurring pain each month for about six months. I told the mother that I suspected the girl had been unwell for some months, but that there was an obstruction at the outlet. On examination I found a firm membranous hymen, which I incised in a semilunar fashion, and the *vis à tergo* was so great that a quantity of treacly fluid was shot right down to the bottom of the bed. I applied a diaper soaked in Condy's fluid over vulva, and in a few days she was all right again, and menstruated regularly afterwards. Now comes the interesting point. Four years later she got married, and four months after marriage she consulted me again, because, as she said, her husband had never been able to have proper connection with her. On examination I found that the opening I had made in the hymen had contracted so that only a fine probe could be passed. This served for the purpose of discharging the menses, but the husband had not been able to penetrate, and the membrane had been pushed up like the finger of a glove for about two inches. She stated that she had only once menstruated since her marriage. I cut a small opening on a director and passed up a rectal bougie and afterwards a finger, when I found she was about three months pregnant. She hardly believed me when I told her so, but about six weeks after she quickened, and six months after she was delivered of a full-time female child. In this case she was *virgo intacta* when three months pregnant.

Another case of quite a different nature I saw last Christmas. A girl of 16 made a charge against the brother-in-law of her master that he had come into her bedroom about midnight and had remained till about four of the following morning, and that during that time he had had repeated connection with her against her will. The man denied the story, and the girl said she was willing to be examined. On examination I found a capacious vagina, with no remnant of hymen. There were no abrasions or contusions either about the genitals, thighs, or abdomen, and I gave the opinion that the girl was not a virgin on the previous night, and that if intercourse had taken place it was not the first time, and had not been accomplished by force, and advised her master to get rid of the girl, as she was dangerous, which he did that day. In this case there can be no doubt but that this girl was not moral, and she was a danger in the house, whether it was true or not that the man had had connexion with her.

I have had several other cases of imperforate hymen, but they are not of interest from a medical jurisprudence point of view.

I am, Sir, yours, &c.,
J. Hamilton, M.D. Q.U.I.

Literature.

PARKE ON HEALTH IN AFRICA. (a)

Since the publication of this volume, the author has passed from among us, and is now beyond the reach of the cavilling of the critical reviewer. The genuine hero of the Emin Pasha Relief Expedition, of whom his chief and brother officers had over and over said that to his skilful and self-denying exertions, they each and all owed their survival during their African pilgrimage, has retired—far too prematurely—to the rest which the labours of his short and brilliant life had so well earned. The consideration of the circumstances might well arrest the censure of a literary or scientific judge if such were called for, but we can emphatically assure the reader that it is not.

This little book consists of 169 pages of text, and a well-prepared index. The former is divided into six principal sections: "The African Continent," "Climate and Meteorology of Africa," "The Nations of Africa," "The Flora of Africa," "The Fauna of Africa," and "The Diseases of Africa." Short articles are appended: "Rules for the Preservation of Health in the Tropics," "List of Useful Articles to Take on an Expedition," "Cooking," "Disinfection," and "Embalming." The whole is written in the modest, unassuming style for which the author's previous works were so worthily noted, and present the equally characteristic features of purity of style and clearness of diction. The first section is geographical and geological; the second, meteorological; the third, anthropological; the fourth, botanical; the fifth is occupied with the domain of natural history; the sixth, the principal section, is devoted to medicine and surgery.

The five earlier sections give a vast deal of concentrated information on their respective subjects. It is all conveyed in a light, gossiping style, easily read, easily understood, and full of interest to every prospective African traveller. The section which deals with the diseases of Africa describes in simple, non-technical language, the nature, symptoms, and treatment of the principal diseases and injuries from which tropical travellers are especially likely to suffer. As the "Guide" was specially written for the benefit and instruction of laymen, and meant to give them information on the nature and treatment of medical and surgical emergencies arising when the sufferer is out of the reach of skilled professional assistance, minutiæ of detail, and scientific technicalities have been avoided throughout, very much to the benefit of the class of readers for whom this little book is intended.

The work is introduced to the public by a preface written by Mr. H. M. Stanley, who expresses the surprise that many will now feelingly share, "that Surgeon-Major Parke, who performed such splendid services in Africa, and won such general commendation from his white and black companions, shoufd have remained to this day so little appreciated by the Government he serves, and the service which he adorns, as not to have received one word of thanks, or decoration, or acknowledgment from either of them." Parke's name lives in the record furnished by his works, and in the testimony furnished by others to his deeds of unselfish heroism. He has furnished a standard for the career of a medical hero, at the attainment of which junior members of the profession can well direct their ambition. Sadly discouraging, we must admit, it is that the noble works and stainless self-denial of Thomas Heazle Parke did not receive more material recognition during his life. Yet we feel sure that he was happier in the performance of his duty than others who appeared to enjoy more of the good things of the world.

It is hardly necessary to add that we most cordially recommend the "Guide to Health in Africa" to all who are interested in the present or the future of the "Dark Continent." Intending travellers and explorers will find it a thoroughly clear and perfectly reliable book of counsel in all the principal medical and surgical emergencies which are likely to arise. A convenient list of all the more necessary medicines and appliances is furnished. These can be best chosen from among the unrivalled preparations of the well-known firm of Messrs. Burroughs, Wellcome, and Co., which Surgeon-Major Parke's experience convinced him, as Mr. H. M. Stanley's had taught himself before, are absolutely unequalled for portability, reliability of action, and unchangeability of strength.

(a) "Guide to Health in Africa, with Notes on the Country and its Inhabitants." By Thomas Heazle Parke, Hon. D.C.L., Hon. F.R.C.S.I., &c., Surgeon-Major, A.M.S., Late Medical Officer to the Emin Pasha Relief Expedition. With Preface by H. M. Stanley. London: Sampson, Low, Marston, and Co. 1893.

KELYNACK'S VERMIFORM APPENDIX. (a)

This volumne represents a large amount of careful clinical observation combined with journalistic and literary research. It embodies a thesis "presented to the Victoria University as a dissertation for the Degree of Doctor of Medicine," and is accordingly more a *résumé* of our knowledge of the subject of appendicular disease, than a treatise embracing original observations on the subject and throwing light on some of the obscurer phases of diagnosis and treatment. The introductory chapters deal with the anatomical details and relations of the vermiform appendix, followed by sections dealing with such varied causes of disease as cystic dilatation of the appendix, abnormal contents of the appendix, and inflammatory affections of the appendix, embracing the varieties of *simple, perforative, recurrent, tubercular, typhoid,* and *actinomycotic* appendicitis. Each of these forms is dealt with in a separate section which embraces all the most recent observations on these varieties of the disease. Chapters on new growths in the appendix, on diagnosis, and on treatment conclude the work, which throughout bears evidence of careful and accurate research. The bibliography alone deserves mention as a record of the thoroughness with which the work has been done. It extends to fifty pages, and includes everything in the literature of the present century that throws any light on the pathology, diagnosis, and treatment of the various forms of appendicitis, many of which are admittedly obscure and deserving of the fullest investigation, both from the urgency of the symptoms to which they give rise, and, in the majority of cases, the necessity of immediate surgical intervention if a favourable result is to be looked for. To all physicians and surgeons who recognise the insidious and dangerous nature of the disease we can recommend Dr. Kelynack's book as one thoroughly up to date and containing the latest information on this important subject.

BLAND SUTTON ON TUMOURS. (b)

It is a bold man who, in the year of grace, 1893, publishes an authoritative work on tumours. Pathology is in a markedly transitional state, and what is apparently true of a morbid growth to day, may be found next year to be untrue. Before starting our perusal of the book, we turn to the index to find what our author may have bave to say for or against the psorospermosis theory of malignant tumours. But the word "psorospermosis" is not there. Then we look up the index of names to see if we can get at his thoughts on this subject by references to the names of Jackson, Clarke, and Ruffer. But again we are disappointed. Commencing, then, with the preface—as, perhaps, we ought to have done at first—we see that Mr. Sutton had "determined to eliminate all those conditions, often classed with tumours, which have been demonstrated to depend on micro-organisms. This cleared the ground in a satisfactory manner," we are assured.

Then, is Mr. Sutton satisfied that the sarcomata and carcinomata which he is about to describe are not caused by micro-organisms? Obviously he is. For our own part, we are content to admit that our mind is not made up on the subject. Time will show. And if Time, the Avenger, should prove Clarke's theory to be established, the psorozoa will be found occupying a position of far greater importance than the echinococci, of whose morbid influence, however, the author duly treats.

It is pleasant to find that developmental pathology is not regarded by Mr. Sutton as having yielded even to his enthusiastic and speculative view all his secrets. Some pathologists write and speak as if the microscope had solved all histological difficulties. Not so our author: "When a tumour composed of slender fusiform cells occurs in such an organ as the ovary, where myomata, fibromata, and sarcomata also occur, the distinction on histological grounds alone is often impossible" (p. 49). To the truth of this statement we cordially subscribe.

It would be impossible to conclude even a short notice of Mr. Sutton's book without alluding to the richness of its illustrations. It contains 250 engravings and 9 plates. Some of these are new, some are well known, and almost all of them are excellent. Nevertheless, we cannot help thinking that in some places he has been over-lavish with his figures. Thus, page 29 is almost entirely occupied with the large figure of a fish with osteomata; page 56 is half-occupied with a prognathous head, when merely the keloid of an ear-ring puncture is to be shown; and a full-page chromo-lithographic plate (No. VI) is used to show an inflamed sebaceous cyst near the mamma.

The value of the drawings of microscopical objects throughout the volume is greatly diminished by the fact that they are entirely regardless of proportion and scale; there is nothing to indicate the degree in which the objects are magnified. In Fig. 50, for instance, the elements of a spindle-celled sarcoma are represented of enormous size—very many times as large as some spindle-cells shown on the opposite page—which are, let it be granted, of the "small" variety. This general and unfortunate want of proportion is due no doubt to the fact that Mr. Sutton has gathered a large proportion of his microscopical drawings along the sea-shore of pathological literature after an ebbing tide. Without doubt the value of the microscopic part of his work would be increased if the actual powers used had been specified throughout.

The paper is unusually thick, the type large and clear, and the three-fold index admirably conceived. In conclusion, we would say that the book is original in design, excellent in detail, and as interesting for present perusal as it will be for future reference.

◆

Literary Notes and Gossip.

Mr. J. B. Bailey, Librarian of the Royal College of Surgeons, England, has disposed of a fallacy, apparently widely prevalent, in respect to the real character of Jenner's MS. in the possession of the College. Contrary to common belief the MS. is in truth in Jenner's own handwriting, whereas the reputed original M.S. now being exhibited in London is the rough draft taken down at Jenner's dictation by his brother in law. The interest of these MS. is also increased by the fact that both contain additions made by Jenner himself. The MS. came to the College in 1879 direct from the Jenner family.

⁂

A fourth edition of Dr. Douglas Powell's well-known work on Diseases of the Lungs (London: H. K. Lewis) has just made its appearance. Although it was not found necessary to make any material change in the present edition, a chapter has been added on the interesting affection, actinomycosis of the lungs. The anatomy and functions of the lungs are fully dealt with, and so is the physical examination of the chest. The main features of the book, however, are so well known that there is no need to attempt to describe them in detail.

⁂

Among other announcements of new editions of standard works we notice the sixteenth edition of "Squire's Companion to the British Pharmacopœia." A copy of the new edition has not yet reached us, but we understand that the alterations and additions have been of such an extensive nature as to constitute it almost a new book. It has, moreover, been corrected with the latest editions of the Pharmacopœias of America, Germany, Russia, Italy, Denmark, Switzerland, &c., and brought up to date in every department. A fifth edition of Macnaughton Jones and Stewart's "Diseases of the Ear and Naso-pharynx" is also announced, the rapid exhaustion of previous editions bearing testitomy to the practical value of the work.

⁂

We welcome *Science Progress* among us with an enthusiasm which reflects the admiration all must feel for the truly British pluck evidenced by the publication of a half-a-crown "monthly review of current scientific investigation." Readers expect such a lot of reliable information for that sum that the editor will have his hands full in endeavouring to satisfy them. The new periodical is "conducted" by Mr. Henry C. Burdett—whatever that may mean—the editor being Mr. J. Bretland Farmer, M.A. No. 1, vol. i, opens with a recondite article on "Physical Science and its Connections," by Mr. G. F. Fitzgerald, M.A., F.R.S. Three of the seven articles deal with subjects appertaining to departments of science germane to medicine, viz., one by Dr. G. G. Buckmaster on the Origin and Nature of Certain Bacterial Poisons, one on the Present Outlook of Vertebrate Morphology, and a third by Prof. Halliburton on Chemical Physiology. It will be seen that the intellectual banquet consists mainly of *pièces de resistance.*

(a) "The Pathology of the Vermiform Appendix." By T. N. Kelynack, M.D., Pathologist to the Manchester Royal Infirmary, &c., &c. 8vo., pp. 223. London: H. K. Lewis 1893.

(b) "Tumours, Innocent and Malignant." By J. Bland Sutton, F.R.C.S. London, Paris, and Melbourne; Cassell and Co. 1893.

⁂

"Modern Gynæcology," by Charles H. Bushong, M.D., is of American origin, in which the busy practitioner will find a clear common-sense statement of the symptoms of the various diseases of the female sexual organs, the detailed methods of treatment and the appliances which the author has found most effectual. The book is illustrated by many original wood-cuts, which are badly done and are undoubtedly the weak feature of the volume. Fig. 4, on page 25, showing separation of labia and buttocks, is indistinct as to be useless, while Fig. 54, illustrating the correct position of the pelvic organs, cannot be accepted as representing the normal position. Fig. 85, showing the first step in the introduction of a pessary, is decidedly not up to date, as this method causes unnecessary pain except in women with very patulous vaginæ. We can nevertheless recommend the book, and can only hope that a second edition may be demanded, so that more correct and better designs may accompany an otherwise useful text.

⁂

The important book of Professor Bütschl on "Protoplasm and Microscopic Foams" has been translated into English by Mr. Minchin and published by Messrs. Black. It deals with the structure of protoplasm rather than its chemical composition. The Professor found that protoplasm invariably exists in the form of a foam, and he succeeded in ultimately making an artificial foam by mixing an easily soluble powder, such as potassium nitrate, with olive oil. This mixture, he tells us, so exactly resembled real protoplasm as to deceive experienced observers. Moreover, under the microscope the artificial protoplasm exhibits amœbiform movements which are accelerated by heat. These experiments seem to show that some, at all events, of the phenomena hitherto regarded as vital may be referred to a physical origin. Any observations which throw additional light on that obscure biological problem, the nature of life, cannot fail to be of interest and value to the progressive work of modern science.

⁂

The current number of the *International Journal of Microscopy and Natural Science* (Baillière, Tindall, and Cox) fully maintains the reputation this journal has now long enjoyed among students and lovers of Nature. We notice that the editorial work is shared by writers who have acquired a reputation in the departments over which they have undertaken to preside, so that the knowledge imparted will be kept up to date. The present number opens with an interesting paper "On the Border Land of Life," in which the writer chiefly dwells on the more important results of modern microscopical research. Then follows an instructive article upon those marvellous species of animal life commonly known as Rotifers, and about which so much has already been written, but their life-history is apparently quite inexhaustible. Mr. Vine finds something new to say about "Predacious and Parasitic Enemies of the Aphides," and among numerous other papers of interest we have one "On the Relation of Nerves to Odontoblasts and the Growth of Dentine."

⁂

New Books and New Edition.—The following have been received since the publication of our last monthly list:—A Handbook of Medical Pathology, by W. P. Herringham, M.D., F.R.C.P. Lond, A. E. Garrod, M.D., F.R.C.P., and W. J. Gow, M.D., M.R.C.P. International Clinics, edited by Drs. Keating, Dalland, Bruce, and Finlay, vols. i, ii, iii, and iv. The Medical Annual for 1894, vol. xii. Syphilis in the Innocent, by L. Duncan Bulkley, A M., M.D. Manual of Practical Hygiene, by W. M. L. Coplin, M.D., and D. Bevan, M.D. Student's Handbook of Medicine and Therapeutics, by Alex. Wheeler, L.R.C.P. Congenital Affections of the Heart, by Geo. Carpenter, M.D. Lond. Lectures on Genito-Urinary Diseases, by J. Ogilvie Will, M.D. The Rectum and Anus, by C. B. Ball, M.D., F.R.C.S.I., 2nd ed. St. Bartholomew's Hospital Reports, vol. xxix, edited by W. S. Church, M D., and W. J. Walsham, F.R.C.S. Burdett's Hospitals and Charities for 1894. Calendar of the Royal University of Ireland for 1894. The Health Resorts of Europe, by Thos. Linn, M.D. Formulaire des Medicaments Nouveaux, par H. Bocquillon-Limousin, Fifth Edition.

◆

Medical News.

The Health of Dublin.

It appears from the report of the Public Health Committee of the Corporation that the month of February was unhealthy. The total death-rate was 1·33 per 1,000 above the mean rate for corresponding month of preceding ten years, and the zymotic rate was also 0·29 per 1,000 in excess. Influenza and measles were less prevalent, but the other zymotics showed no abatement.

Fees for Certification of Dangerous Lunatics.

The Boyle Board of Guardians has had to climb down and to pay to Dr. O'Riordan, under threat of legal proceedings, his proper fee for certification, with all costs of his solicitor.

Experimental Treatment of Sewage at Worthing

The Hermite process of the treatment of sewage which has been given an exhaustive trial at Worthing has failed. The following is the official report on the process, communicated by the Medical Officer of Health for the borough: "Since there is no instantaneous decomposition of fæcal matter, and no sterilisation of sewage, I am of opinion that the process, as far as the late trials have gone, has therefore failed to produce the results which are claimed for it by its inventor."

Society of Apothecaries, London.

The following candidates, having passed the necessary examinations, have been granted the diploma of L.S.A. of the Society, entitling them to practise medicine, surgery, and midwifery; enabling the holder also to compete for medical appointments in the Army, Navy, and India Service, also for Poor-law appointments, viz:—

Messrs. Austen, Best P., Bird, Burgess, Burton, Chilcott, Danaher, Farman, Galloway, Lattey, Owen, Pooley, and Venis.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

PRELIMINARY EXAMINATION.

The following candidates have passed—

A. The Examination generally—

J. B. Allster, J. W. Bell, J. R. Blackwood, A. P. Bonnar, C. R. Boyce, W. A. Cooke, W. F. Cormack, S. W. Cummings, A. D. C. Cummins, N. T. De Blaquiere, M. Dempsey, D. B. Elliott J. Foley, R. S. Garraway, H. J. Gorman, T. A. Gray, A. E. Griffith, H. E. Hayes, P. Heffernan, R. A. Hegarty, F. A. Hornibrook, J. J. Huston, D. P. James, J. L. Jones, M. W. Kelly, F. C. Large, A. L. Lett, F. Malone, C. H. McCarthy, J. J. McDonald, S. J. McDonnell, J. H. O'Connell, P. S. O'Reilly, D. O'Sullivan, B. R. Roberts, J. A. Russell, J. S. Smith, J. Somers, R. S. Stephens, G. F. Stoney, T. J. Tallant, T. Villiers, A. E. K. B. Williams, J. G. Young.

B. Fractions—completing Certificate passed elsewhere prior to 1892—

B. J. Hannen, P. Hogan, P. M. C. O'Doherty.

C. Physics—under old Regulations—

H. E. Howley, R. H. D. Pope.

Irish Medical Schools and Graduates' Association.

In our report of the dinner and annual meeting for the election of officers the name of Dr. Stewart, one of the hon. secretaries, was accidentally omitted.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of The Medical Press and Circular, may now be had at either office of this Journal, price, 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

THE DICKINSON TESTIMONIAL FUND.

The Hon. Secretary writes us that a general meeting of the subscribers to this fund will be held in the Board Room of St George's Hospital, on Tuesday next, the 10th inst. His Royal Highness the Duke of Cambridge, K.G., has consented to preside on the occasion, and will take the chair at 12 noon. The subscription list will then be closed. Intending subscribers should communicate before that date with either Mr Laurence Reid, Hon. Treasurer, at 11 Petersham Terrace, S.W., or Dr. Gerard Carré, Hon. Secretary, at 1 St. George's Place, S.W.

Dr. E. Haughton.—You do not adduce any new facts or arguments in your letter, the length of which during the present great pressure on our space renders it impossible for us to insert.

AN URETHRAL LUBRICANT.

N. O. P.—A very good lubricant can be prepared by the following formula:—

Powdered soap, oz j.
Glycerine and water, āā dr. iv;
Corrosive sublimate, gr. ss.

This is a far more efficacious lubricant than vaseline or fatty substances.

Dr. J. B. N.—We have not quite decided what to do with the M.S. referred to. It is the case from the other side, and would probably lead to considerable controversy, which we have at present not space for. We have carefully read your leaflet and shall keep it for reference.

Mr. C. G. Y.—Thanks for the cutting, but you will see we have already referred to the matter on reference to our last.

SECTION MOUNTING.

Student.—You will find the information in any and every treatise of practical histology. The latest suggestion for a mounting medium is "soluble glass" (*Chemist and Druggist*, March 31st, page 485), which is said to possess various advantages over Canada balsam.

F.R.C.S.—Some authorities hold that a leprous man should have no sexual intercourse with his wife, the reason given being that no healthy child can be born of a leper. If, therefore, a leper has a wife, it is his duty to leave her. Our correspondent should consult the volumes of the Journal of the National Leprosy Fund, in which he will find all the information of which he is in need.

THE KING OF DELHI AND OPIUM.

It is a fact known to me, writes a correspondent, that when the King of Delhi was made prisoner (in 1858) he complained soon after to his English physicians of suffering from indigestion brought on by their refusal to allow him to continue taking the usual daily treatment he had followed for forty years, namely, beginning his morning with an emetic, followed by an opium pill. In a short time afterwards he was able to make a good breakfast. The opium in no way tended in his case either to shorten life or act as an aphrodisiac, although he was the reputed father of some forty children, or more, and had attained to nearly eighty years of age when he died.

A Subscriber (Nottingham).—Dr. Clark's process for reducing the hardness of water consists of the use of lime applied in the form of milk or as a filtering medium, whereby the carbonic anhydride enters into chemical combination with the lime to form insoluble carbonate of calcium, and consequently a portion of the dissolved carbonate of calcium is precipitated from the water.

Surgeon-Major J. C.—The point has still to be definitely determined whether bacteria are present in the vagina of a healthy woman. Our correspondent will find the subject discussed in the report of the meeting of the Obstetrical Society, London, for January 3rd, 1894.

Meetings of Societies, Lectures, &c.

Wednesday, April 4th.

West London Hospital (Hammersmith).—At 5 p.m., Dr. Seymour Taylor: The Therapeutics of Heart Disease. (Post-Graduate Lecture.)

Thursday, April 5th.

Harveian Society.—At 8.30 p.m., Clinical Evening. Dr. James Taylor: Two cases of Friedreich's Ataxy; Dr. G. A. Sutherland: Gummata of the Liver in a Child. Cases shown also by Drs. Sydney Phillips, Dr. Boxall, and others.

Friday, April 6th.

West London Medico-Chirurgical Society (West London Hospital) At 8 p.m., Specimens:—Mr. S. Mallack Bluett: Foreign Body Swallowed and passed per anum; Mr. P. Macleod Yearsley: Fibroma of Ovary. Papers: Mr. F. Bowreman Jessett: The Treatment of Advanced cases of Carcinoma of Uterus; Mr. L. A. Bidwell: Remarks on Amputation of the Breast for Cancer Mr. W. H. Battle: Two cases of Malignant Disease of Penis.

West Kent Medico-Chirurgical Society.—At 8 p.m., Discussion on Headache.

Vacancies.

Bedford General Infirmary and Fever Hospital.—House Surgeon. Salary £100 per annum, with apartments, board, lodging and washing. Applications and testimonials to the Secretary on or before April 10th.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Pathologist. Salary 100 guineas per annum. Applications and testimonials to the Secretary on or before April 12th.

Nottingham.—Assistant Medical Officer (unmarried) to the Coppice Asylum for Private Patients. Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications and testimonials to Dr. Tate on or before April 14th.

Oldham Infirmary.—Senior House Surgeon. Salary £80 per annum, with board and residence. Applications and testimonials to the Secretary on or before April 10th.

Royal Victoria Hospital, Bournemouth.—House Surgeon and Secretary. Salary £100 per annum, with board. Applications and testimonials to the Chairman of Committee on or before May 1st.

Royal Hospital for Diseases of the Chest, City Road, E.C.—Resident Medical Officer. Salary £100 per annum, with furnished apartments and board.

York Dispensary.—Resident Medical Officer (unmarried). Salary £150 per annum, with furnished apartments, &c. Applications and testimonials to W. Draper, Esq., De Grey House, York, on or before April 10th.

Appointments

Chadwick, C. M., M.A. M.D., M.R.C.P., M.R.C.S., Honorary Physician to the Leeds General Infirmary.

Edmunds, D. T., L.R.C.P., L.M.Edin., M.R.C.S., Honorary Surgeon to the Bathurst Hospital, New South Wales.

Edwards, E. C., M.B., C.M.Edin., Junior House Surgeon to the East Suffolk and Ipswich Hospital.

Fiffe, W. K., M.B., M.R.C.P., Medical Registrar to St. George's Hospital.

Guinand, P., M.D Berne, L.R.C.P.Lond., M.R.C.S., Health Officer for Narracan Shire, Victoria, Australia.

Lane, T., L.K.Q.C.P., L.M., L.R.C.S.Irel., Medical Officer to the Inverell Hospital, New South Wales.

Macalister, C. J., M.B.Ed., M.R.C.P., Consulting Physician to the Liverpool Schools for the Deaf and Dumb.

McCall, J., M.B., Ch.M., Glasg., Government Medical and Health Officer for the District of Devon West, Tasmania.

McInery, J., M.D.New York, L.S.A.Lond., Public Vaccinator for North Carlton, Victoria, Australia.

McKillop, R., F.R.C.S., L.M., L.R.C.P.Edin., Medical Officer to the Goulburn Hospital, New South Wales.

Moore, J. B., L.K.Q.C.P., L.R.C.P.Irel., Honorary Surgeon to the Bathurst Hospital, New South Wales.

Nevins, J. E., M.B.Lond., M.R.C.S., Honorary Medical Officer to the Liverpool School for the Deaf and Dumb.

O'Connor, J. E., M.B., B.Ch.Irel., Medical Officer for the Glenfield Sanitary District of the Blaby Union.

Stevenson, E., M.D., C.M.Aberd., Assistant Surgeon to the Liverpool Eye and Ear Infirmary.

Symes, R. H., L.K.Q.C.P., L.M., L.R.C.S.Irel., Surgeon to the Victoria Hospital at Barcaldine, Queensland.

Tolker, S. G., M.B.Lond., Resident Assistant Physician at St. Thomas's Hospital.

Trevelyan, E. F., B.Sc.Lond., M.D., M.R.C.P., M.R.C.S., Professor of Pathology in the Medical Department, Yorkshire College.

Williams, E. H., M.D., Ch.M.Toronto, L.R.C.P.Lond., Health Officer for Upper Yarra Shire, Victoria, Australia.

Births.

Constant.—March 30th, at Argyll Lodge, Scarborough, the wife of Thos. E. Constant, M.R.C.S., L.R.C.P.Lond., L.D.S., of a daughter.

Harford-Battersby.—March 27th, at Mornington Road, Bow, the wife of Dr. C. F. Harford-Battersby, of a son, who died at birth.

Deaths.

Clarke.—March 27th, at his residence, Nostell, Wakefield, W. Barnard Clarke, M.D.Ed., J.P. for Ipswich, aged 87.

Crompton.—March 31st, at his residence, 40 Harborne Road, Edgbaston, Dickinson W. Crompton, F.R.C.S., F.L.S., aged 88.

Duggan.—March 24th, at Woodville, Athenry, Co. Galway, Joseph M. Duggan, M.R.C.P.Irel., of cardiac syncope, aged 64.

Guest.—March 21st, at his residence, 263 Oxford Road, Manchester, Ellis Southern Guest, Surgeon, aged 70.

Irwin.—March 30th, at Gloucester, Alan Montgomery Irwin, L.R.C.S.I., L.K. and Q.C.P.I.

Knight.—March 23rd, at his residence, Etna Lodge, Clones, Alexander Knight, M.D.

Nelson.—March 26th, Thomas Andrew Nelson, M.D., of Nottingham Terrace, York Gate, Regent's Park, N.W.

Pycroft.—March 23rd, at Wellesley, Torquay, George Pycroft, M.R.C.S.E., of Camborne Terrace, Richmond, Surrey, aged 74.

Woodcock.—March 30th, at Forest Hill, of diphtheria, Arthur Woodcock, L.R.C.P.Lond., M.R.C.S., aged 22.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

"SALUS POPULI SUPREMA LEX."

VOL. CVIII. WEDNESDAY APRIL, 11, 1894. No. 15.

Original Communications.

SOME PRACTICAL OBSERVATIONS ON THE EXAMINATION OF AN EAR AND THE ÆTIOLOGY OF AURAL AFFECTIONS.

By H. MACNAUGHTON JONES, M.D., M.Ch., M.A.O. (Hon. Cau.), F.R.C.S.I. & E.

So much depends upon the correct and thorough examination of an aural case, that a few observations on this subject may not be without their use to practitioners generally. Hurry or carelessness in the steps of such preliminary investigation may lead to an error of diagnosis which may be fatal, not alone to the hearing, but also to the life of the patient, and as a minor consequence must act prejudicially to the surgeon himself.

A mistake arising out of such negligence may prove most serious to his general reputation.

We shall see that there are many possibilities of error, even when extreme caution is exercised, and when close attention to detail has been given to the causation, signs, and symptoms of some aural affection.

Let us briefly summarise the points necessary to be attended to in this primary investigation.

It is no exaggeration to say that before the speculum is taken in hand, or the auscultation tube employed, a critical inquiry into the antecedents of the case will afford in the large majority of instances a fair insight into the nature of the affection we are called upon to diagnose and treat.

These antecedents include such evidence as hereditary transmission, the sequelæ of the diseases of infancy and childhood, more particularly tubercle, and the exanthemata; habits, occupations, injuries, and individual susceptibilities; the precedence or contemporaneous occurrence of such symptoms as pain, discharge, tinnitus, or vertigo, in relation to the deafness.

We shall in this manner gain so much valuable information as may give us a clue to such primary sources of the ear mischief as gout, influenza, naso-pharyngeal catarrhs and congestions, scarlet fever or measles; sea bathing, residence in the tropics, over mental and physical strain; such occupations as gunnery practice, or night nursing; railway travelling or collisions; a sedentary calling with confinement indoors; frequent exposure to cold and damp, or possibly to some special malarial influence, as, for example, intermittent, Roman, or Malta fevers.

Nor are we to pass lightly by collateral symptoms complained of in heart palpitations, insomnia, dental neuralgia, ocular migraine, or obstructed nasal respiration.

Anæmia, tinnitus, and vertiginous attacks are not uncommonly associated. Tinnitus is a frequent attendant upon irregularity of cardiac ryhthm, or feeble systole, as also in organic diseased conditions. both of the heart and aorta. Dental irritation, especially in the third molar, may cause both aural neuralgia and tinnitus. Ocular migraine may be one of the manifestations of the low vascular tension which precedes the occurrence of tinnitus, and interference with nasal breathing leads directly both to deafness and noises in the ear.

With reference to malarial fevers I may observe that in my experience such causes of aural trouble are likely to produce not only recurrent attacks of otitis media, but are occasionally followed by lurking mischief of a chronic character in the middle ear, with possible secondary consequences in the mastoid cells and antrum; a fact which it is well to remember in the treatment of any outer or middle ear affections which may follow upon them.

It may be noticed that I have not included in the foregoing category of causes a history of syphilis, inasmuch as I have found the association of syphilis, and morbid conditions of the middle and internal ear, of very rare occurrence. This remark does not apply to hereditary syphilitic taint, as deafness is not uncommonly linked with other manifest signs of transmitted specific disease, such as are usually seen in the teeth and cornea.

It is a noteworthy fact that the ear does thus escape, while the nose, tongue, and throat, specially suffer from acquired syphilis.

At times temporary deafness, with some tinnitus, does occur in the exanthematous stage of the disease, and generally yields rapidly to treatment. Specific aural troubles which occur in after years are some of the "reminders" of the primary affection, and are devoid of any special objective proof of the connection, save that which may be found in a dull greyish and lustreless membrane.

Quite different is it in the case of gout, both as regards its hereditary effects, and its consequences when acquired.

It is not in those who are subject to the more active manifestations of gout in the various crises which periodically occur, that we meet most frequently these aural complications; rather are they to be met with amongst those sufferers from obscure and latent evidences of the uric acid diathesis, which, more especially in women, have been transmitted from parents, and are probably encouraged by habit. In these sufferers we constantly find a collateral rheumatic arthritic condition, or the characteristic proofs, in the phalanges of hands and feet, of concurrent gouty and rheumatic states.

Excematous irritations in the neighbourhood of the external ear, or in the meatus, with epidermal shedding and accumulation, which narrow its lumen and render its walls extremely sensitive, while the canal itself is frequently filled with masses of epidermis and cerumen, are the common local signs seen in such individuals. At times we meet with sticky exudations, and not infrequently hyperostosis or exostosis, which both narrow the lumen and imprison *débris*.

It is needless to say that such conditions travel to the membrane and impair its elasticity and vibratile properties. But apart from such visible signs of gout in the outer ear or tympanic membrane, there are those exudative changes in the middle ear which cause impairment of the ossicular movements through interference with the intra-tympanic chain in the malleoincal and inco-stapedial joints, and the stapedial excursions in the round opening, and rigidity of the membrane in the oval opening.

Such intra-tympanic abnormalities may be accentuated by spastic states of the intra-tympanic muscles, which, by traction on the tympanic membrane, lessen the amplitude of its vibrations, and alter its normal fundamental tone. Thus are induced those characteristic symptoms of ossicular rigidity, of loss of differentiating power in the discrimination of complex and associated sounds, to which I will again refer. This defect is commonly shown in the inability to hear conversation at a dinner table, or to distinguish synchronous sounds, as the ticking of two clocks placed in different positions in the same room.

It also affects the accommodative power of the ear in ascertaining without the aid of vision the direction of the sound. Such changes diminish the accommodation in estimating the distance and direction of sound, while, as long since pointed out by Toynbee it may possibly be that the temporary relief of such rigid ossicular conditions, though the general vibration caused, renders hearing during a railway journey more easy. I have referred to intermittent fevers as a cause both of tinnitus and deafness, the former symptom often preceding the latter, and both being quite independent of a therapeutical origin, which may, however, induce or exaggerate them: namely, the prolonged administration of large doses of quinine, and the consequent hyperæmia of the labyrinth induced thereby.

I believe, however, as has been so clearly shown by Weber-Liel, Löwenberg, and American authors, that a peculiar predisposition to both deafness and tinnitus, or possibly Menière's vertigo, attends upon these microbal influences which have their origin in malariaand miasm. In an ordinary zymotic fever such as typhus, and in remittent fever, during the occurrence of which deafness has been present, or has remained through convalescence, and in which quinine has been given in large quantities to the full therapeutical effect, both the deafness and tinnitus usually disappear after the subsidence of the fever and the cessation of the exhibition of the drug. Nor is *permanent* deafness often to be traced to the occurrence of such fevers as typhoid or typhus.

Far different is it in the case of malarial diseases, and influenza participates with them, as it does in so many other respects, in these otological sequelæ, of which otitis media, with or without perforation, is one of the most frequent occurrence, and persistent tinnitus another. The subjective noises which remain after influenza and are associated with other transient and reflex nerve excitations are but a link in the chain of complex nervous disturbances which we so commonly find occurring after an influenzal attack, and which are frequently accentuated by an associated insomnia.

It goes for the saying that scarlet fever is one of the commonest sources in early life of permanent impairment of hearing. We may hope that this will be less so, when the vital importance of attention to the naso-pharynx and the ear, both during, and immediately after, an attack of scarlatina, is more widely recognised.

Systematic disinfection of the nasal passages and the naso-pharyngeal space, early attention to pain in the ear, with resort to paracentesis of the tympanic cavity, when an inflamed and bulging membrane indicates accumulation of secretion therein, are our most valuable safeguards.

It is true that in some instances the inflammatory process is so rapid and so fierce, that discharge followed by perforation occurs without giving the surgeon time to take special prophylactic measures. Yet in these cases post-nasal medication, and the insurance of thorough cleanliness of the meatus and tympanic cavity, will do much to limit the destructive effects. And it is marvellous what excellent hearing power may remain even with a large perforation of the membrane, so long as the stapes are still intact.

The effects on the ear of measles, though by no means so severe as those of scarlatina, are of sufficient gravity to warrant watchful care, especially during convalescence from the exanthem. Eustachian collapse and closure, imprisonment of secretion in the tympanum, or what we may regard as chronic catarrhal states of its membrane, are the conditions to be more commonly apprehended. This is particularly the case in children, who, at the time of the attack, and previously to it, have suffered from post-nasal adenoid growths and hypertrophic conditions of the turbinate bodies.

Here, again, close attention to the naso-pharynx, by spray and douche; the reduction of any chronic turbinate hypertrophy; the immediate removal of adenoid vegetations, and the establishment of free ventilation of the tympanic cavities, by securing the patency of the Eustachian tubes, are the surest means of anticipating any secondary aural mischief.

The same rule applies to diphtheria, and the deafness which followed it, more particularly the nasal variety.

Here the value of Faradisation of the tubal and palatal muscles, is specially to be insisted upon, as the innervation of these structures which follows even mild diphtheritic attacks, is in itself the most likely cause of the deafness.

A short time since I had to treat a very sharp attack of otitis media, with threatened mastoid inflammation, arising from rash diving on the head in the sea. It is most important to remember this cause of deafness when we are consulted by those who are suffering from any defect of hearing associated with middle ear mischief. It is generally from the act of diving on the head, or the forcible dipping of children's heads under water, that this trouble arises. Immediate attention should be given to the condition of the Eustachian tube, which is not infrequently closed through a partial swelling of its walls, and which alkaline douching, and a gentle catheterisation, with the use of Politzer's inflater, will remedy. Sojourning by the seaside, all such patients, and those suffering from chronic suppurative states of the middle ear, should not be allowed to dive, or to plunge the head beneath the water when swimming.

In most of the cases in which we are consulted for deafness, among those who are exposed to the effects of either loud noises or concussions, as in the instance of railway *employés*, there are no evidences of any gross changes in the tympanum. Noises are very often heard, the deafness is of a progressive character, and the prospect of amelioration are very slight.

The effects of either mental or physical overstrain, or both combined, in producing deafness and subjective noises in the ear, are specially worthy of consideration. In such cases we find both middle and internal ear disturbances—the former being induced by tubal innervation and defective ventilation of the tympanum. This is followed by paretic states of the intra-tympanic muscles, and want of equilibration of the air in the tympanic cavity, incomplete ossicular movement, abnormal curvature of the drumhead, with resultant defective action of the vibratile media between the outer ear and the labyrinth.

The latter is often the result of altered states of tension of the blood vessels of the labyrinth, due to vasomotor exudation or depression, or, it may be, that the auditory disturbance has its source in the abnormal stapedial influence on the labyrinthine fluid.

These are some of the more important inquiries into the predisposing causes, whether constitutional or local, which should always be made before commencing the steps of an aural examination. I shall have something to say to the more particular details in the next communication.

(*To be continued.*)

◆

ON CASES OF ASSOCIATED PAROVARIAN AND VAGINAL CYSTS FORMED FROM A DISTENDED GARTNER'S DUCT.

By AMAND ROUTH, M.D., M.R.C.P.Lond.,
Obstetric Physician to, and Lecturer on Practical Obstetrics and Gynæcology at, Charing Cross Hospital.

The first of these cases was under my own observation. The patient was a married woman. æt. 25, who came complaining of pain in the right ovarian region with a profuse watery, occasionally offensive discharge from the vagina. The abdomen was somewhat distended. *Per vaginam* the uterus was found to be mobile but pushed to the left by a somewhat elastic mass on the right side. This tumour appeared to be situated between the layers of the broad ligament; it was partially mobile independently of the uterus and tender. Along the vaginal wall could be felt, passing from the base of the right broad ligament, an elastic ridge, irregular in outline, which tended towards the median line, ultimately losing itself somewhere to the right of the urethra. I was unable to ascertain whence the discharge came, but I noticed that the upper part of the vagina was comparatively dry, while the lower portion was bathed by a viscid offensive secretion. A fortnight later the temperature rose, with a throbbing pain, and the vaginal ridge became larger and more markedly elastic, evidently containing fluid, and it could now be felt reaching almost to the vaginal outlet. On pressing the vaginal tumour the contents disappeared, thus establishing the existence of a communication with the cyst higher up. When the patient made bearing-down efforts the vaginal ridge became more full and tense. I examined the patient under ether, when the broad ligament tumour could be distinctly made out to be parovarian, and in view of its communication with the vaginal cyst it was assumed to be due to patency of a persistent Gartner's duct. A quantity of yellow offensive pus escaped during the examination, pouring from a minute orifice just beneath the urethral opening. With some difficulty I succeeded in passing a probe giving exit to a further quantity of pus. The sound passed upwards and outwards for a distance of five inches evidently entering the broad ligament cyst. I washed out the cysts and left in a drainage tube. The discharge continued for nearly five weeks, gradually becoming more and more watery. When the patient was examined again a year later I could feel a trough in the vaginal wall leading into a canal one inch long, terminating in a cul-de-sac. (The author then referred to two similar cases, one by Watts, and the other by Veit. He also read notes of two analogous cases of patency of the whole length of the duct with an anterior opening allowing free discharge, thus preventing distension of the duct along its course.) From a consideration of these cases I think I am justified in formulating the following propositions :—

(1) That Gartner's duct can be traced in some cases in the adult female from the parovarium to the vestibulum vulvæ, ending just beneath and slightly to one side of the urethral orifice.

(2) Homology tends to show that Max Schüller's glands are diverticula of Gartner's ducts, just as the vesiculæ seminales are diverticula of the vasa deferentia. He added that there was reason to believe that Skene's ducts are not necessarily identical with the anterior termination of Gartner's ducts (as most of those who have traced Gartner's duct to the vestibule appeared to think), but that Skene's ducts led directly and solely from Max Schüller's urethral glands, Gartner's ducts being continued to the vestibule behind, but parallel to, Skene's ducts.

(3) That Gartner's duct, if patent, might become distended at any part of its course constituting a variety of parovarian cyst if the distension were in the broad ligament portion, and a vaginal cyst if the distension were in the vaginal portion. The cases I have described were all instances of the association of both of these cysts owing to simultaneous patency and distension of both portions of the duct.

(4) These cases may afford some explanation of obscure watery discharges from the vagina not coming from the uterus or bladder.

(5) In regard to treatment when the whole duct is distended, the vaginal portion should be laid open as far as the base of the broad ligament, and the broad ligament portion encouraged to contract and close up.

◆

REMARKS ON AMPUTATION OF THE BREAST FOR CANCER. (*a*)

By LEONARD A. BIDWELL, F.R.C.S.,
Senior Assistant Surgeon to the West London Hospital, &c.

In the following remarks I wish to confine myself entirely within practical lines, and do not intend to refer to any of the pathological problems connected with this subject, except in so far as they influence the kind of operation to be done.

There are two points to be considered when determining the success of any operative procedure for cancer: the first is the immediate mortality of the operation, and the second is the prospect of an ultimate cure.

With regard to the mortality of the operation of amputation of the breast, even in the pre-antiseptic days there were not many deaths, but with the introduction of imperfect antiseptic measures a more severe operation began to be practised, which caused a rather higher mortality, so that most statistics are misleading; in fact, even Lister lost 8 p.c. of his cases, while in Billroth's hands as many as 23 p.c. died. However, with more simple antiseptic measures, and especially the absence of the spray, and avoidance of any undue exposure of the chest, the mortality now is extremely low. For my own part, during the last three years I have not known of a death due to the operation, and this among some 63 operations occurring both in my own practice and in that of other surgeons whom I have assisted. Last year, too, Dr. Dennis (*b*), of New York, published a series of 71 consecutive cases of thorough breast operations for cancer with only one death, and that one occurred in a patient suffering from hæmophilia.

With regard to the second point, it must be admitted that all our procedures at present show unsatisfactory results. It has usually been considered that, if a patient remains free from recurrence for three years after the primary operation, she may be counted as cured, and the number of cures after operation are estimated in this way; but unfortunately the rule cannot be considered as absolute, I have myself seen one case where a recurrence occurred in the axilla five years after the first operation. According to Sir James Paget, the average duration of life of patients suffering from mammary cancer is two years, while after operation the average duration became 2 and 1-12th years: this gain, which is not encouraging, of course refers to incomplete operations, and it is reassuring to find that

---

(*a*) A paper read before the West London Medico-Chirurgical Society, April 6th, 1894.

(*b*) "Trans. Amer. Surg. Ass.," vol. ix, p. 219.

some of the modern statistics show that a considerable number of patients now pass the "three-year limit" without recurrence. Thus Kuster reported that in 25 p.c. of his cases there was no recurrence within this time, and Dennis is able to raise the percentage of "cures" to 30.

The great improvements in the ultimate result of this operation must be attributed to the increased thoroughness and care in its performance. That the whole of the breast ought to be removed in every case is now admitted by the greater number of surgeons, although Mr. Butlin in his "Operative Treatment of Malignant Disease" unfortunately supports the idea that it is only necessary to remove the tissues within a certain distance of the growth. I am sure there is a great risk that recurrence will take place in the gland tissue which has been left, and in the only three cases in which incomplete removal of the breast has been practised under my observation recurrence has occurred in the remaining gland tissue.

Another point to which too much importance cannot be attached is the removal of a sufficient quantity of skin over the breast. It is not enough to remove the skin which is adherent to, or which "dimples" over the tumour, but practically the skin over the whole breast should be included in the incisions. It formerly was a rule that as little skin as possible should be removed, so as to ensure the coaptation of the edges of the wound after the operation; but now the incisions should be quite regardless of this point, as any separation between the edges can readily be filled in with Thiersch's grafts as suggested by Mr. Cheyne, (*b*) and this too without increasing the duration of healing. The reason for an apparently reckless removal of skin is to be found in the fact, pointed out by Prof. Heidenham, that breast tissue extends into the suspensory ligaments of the breast; these ligaments are connected with the skin close to the margin of the breast, and would not be removed if only a little skin round the nipple were to be excised. There might not be so much danger in leaving these small outlying portions of breast tissue, but for the evidence that Dr. Stiles of Edinburgh has brought forward to show that the cancerous infection takes place entirely by the lymphatic channels which are extremely abundant and freely interlace in every part of the breast tissue, and so one could not be sure that these little pieces of glandular tissue were not already infected.

One must also urge the importance of removing not only every actually enlarged gland, but also of absolutely clearing out the axilla, in every case of scirrhus of the breast. To this rule there should be no exception, even when the growth is situated on the extreme inner edge of the breast. In one of my cases where the growth was in this position, almost disconnected from the breast, a microscopic examination of the axillary glands showed that these were infected with cancer. Kuster, too, has examined microscopically the lymphatic glands from 117 consecutive cases, some of which were not obviously enlarged. He found evidence of cancer in all but two specimens.

Furthermore, it has been stated that in 90 p.c. of cases where general infection has taken place this has come about through the axillary glands, we also find that 50 p.c. of the metastatic deposits occur in the lung or pleura of the same side as the growth, and the apex of the lung is most often attacked, probably infected by direct continuity from the axillary glands.

With regard to the incision to be made, I think that no definite rule should be made; it is better to suit the incision to the case. The old standard transverse incision is good in certain cases, especially when the growth is situated at the extreme outer edge of the breast. For tumours situated at the upper edge or middle of the gland prefer two vertical incisions which enable one to remove nearly all the skin over the breast, and to bring the edges together afterwards; with the vertical incision a cross-cut into the axilla is also necessary. For tumours situated at the lower margin of the breast a diagonal incision from the growth to the axilla answers well.

It has long been recommended that the fascia over the pectoralis major should be removed with the breast, both because the posterior suspensory ligaments join it, and also because it has been supposed to act as a barrier against the invasion of the growth, but this is not the case, the pectoral muscle itself often is, or later becomes involved by the growth. I have seen three cases of recurrent scirrhus where the recurrence was situated entirely in the pectoral muscle; last summer too I operated on a patient with a scirrhus of the upper margin of the breast where nearly the whole thickness of the muscle was infiltrated, and so had to be removed.

In consequence of the occurrence of secondary deposits in the pectoral muscle, Dr. Halsted, (*c*) of the John Hopkins Hospital, has suggested that in every case of amputation of the breast for scirrhus the whole of the pectoral portion of the pectoralis major should be excised. When this has been done the division of the pectoralis minor gives a most complete exposure of the axilla, and enables the surgeon to readily remove every gland, even those between the first rib and clavicle. Last year Mr. W. A. Lane (*d*) urged a similar operation in any case where the growth extended close to the pectoral muscle.

Halsted's operation seems to me to be rather too severe for every case, and I have only been obliged to perform it once, when the result was very satisfactory, and even the impairment in movement of the arm was very slight. It remains to be seen whether a recurrence will be postponed for a longer time after the operation; Halsted himself has not tried it for a long enough time to give statistics.

I have already mentioned that the axilla should be thoroughly cleaned out in every case of cancer, whether the glands are enlarged or not; two cases have come under my notice where the glands were not removed, as no obvious enlargement was felt, a recurrence within a year had to be removed from the axilla in each case. In nearly all the other primary operations for cancer to which I have referred the axillary glands have been removed irrespective of any enlargement, and in every one of my own cases I have scrupulously cleaned out the axilla.

If Halsted's method has been employed the clearance of the axilla is very easy, but if this method be thought too severe a proceeding, a most complete view of the axilla can be obtained by dividing the pectoral portion of the pectoralis major. The cut ends of the muscle are reunited with silk sutures at the close of the operation. In the cases where I have done this, I have not found any loss of movement in the arm. In clearing out the axilla I always proceed to dissect down to the first part of the axillary vein, which is then cleaned from below upwards to the apex of the axilla; when the triangular mass of fat-containing glands has been separated from the vein it can be removed quickly without fear of doing damage to important vessels or nerves.

In those cases where the glands are adherent to the axillary vein, it is better to tie and remove a portion of the axillary vein than to risk leaving any diseased gland tissue behind. I found this necessary this summer in the case of a lady on whom I operated for a scirrhus at the outer edge of her breast accompanied by a huge mass of glands in the axilla; these glands

---

(*b*) *Lancet*, 1891.

(*c*) "John Hopkins Hosp. Reports," vol. ii, p. 277.

(*d*) "Trans. Clin. Soc. Lond.," vol. xxvi, p. 85.

were intimately adherent to the axillary vein, a portion of which, about 1½ inches long, was excised, and the remainder of the separation of the contents of the axilla was easily effected. The patient had absolutely no trouble from the division of the axillary vein; there was neither swelling of hand or pain; she also quickly regained the use of her hand and arm. I saw her six months after the operation, and found that the axilla was quite free.

A large artery and vein, the long thoracic, usually run through the midst of the glands. I have seen much time wasted in attempting to remove the glands without injuring the vessel. I think that the best plan is to clamp and divide it at once. The external mammary artery requires similar treatment. The axillary fat is supposed to be supplied by a small alar thoracic artery only, but in cases of cancer the blood-vessels are much more numerous; in high dissections of the axilla it is not uncommon to divide the external anterior thoracic artery, which sometimes is rather troublesome to secure.

With regard to the axillary glands, I would point out that in some cases the enlargement affects also the glands between scapula and thorax; these therefore must be carefully examined for the least sign of enlargement, and if necessary removed; a couple of glands, too, are situated between the two pectoral muscles, which easily escape detection, but should always be removed.

When the bleeding parts have all been secured by ligatures and the wound washed out with some antiseptic solution, the edges are united as far as possible by silk or silkworm gut sutures. When too much skin has been removed to allow of complete closure of the wound, as much as possible should be united, the space between the edges being covered with Thiersch's grafts; in neither case is it necessary to use a drainage tube. The wound is covered with a piece of gauze protective tissue, and several layers of double cyanide gauze; over this is placed a specially-shaped jacket of wood-wool tissue with a notch at the axilla, and a strip to be wound round the shoulder. A butter muslin bandage keeps the whole in position, and the arm is supported in a sling. In bandaging some pressure should be employed, so as to prevent any accumulation of blood under the flaps.

The wound is not dressed till the eighth day, when the incision is found to be healed, and all stitches are removed. The patient is usually allowed to get up on the fifth or sixth day, and in many of the cases has returned home before the end of a fortnight.

One word as regards the antiseptics employed, for healing without suppuration in hospital practice at least, is only to be obtained by using antiseptic precautions. On the night before the operation the skin over the breast and axilla is washed with soap and water and turpentine. The surface is then "packed" with gauze soaked in 1 in 20 carbolic acid. At the operation it is again scrubbed with soap and a flesh brush, and then washed with ether to remove the contents of the sebaceous follicles; finally some 1 in 1,000 perchloride of mercury solution is run over the part. The other side of the chest, and the bed-clothing, &c., are all covered with macintosh, and towels either sterilised or wrung out in 1 in 40 carbolic solution. Care is taken not to expose any part of the body unnecessarily, and to keep the patient warm. The instruments are preferably boiled for five minutes in a solution of soda (one drachm to a pint) and then transferred to carbolic acid solution 1 in 40. No irrigation is employed during the operation, but before the wound is closed it is thoroughly sponged out with 1 in 2,000 solution of corrosive sublimate and dried; during the dissection of the axilla the main wound is covered with a piece of gauze soaked in mercuric solution.

I use silk ligatures, which have been sterilised by boiling for half an hour in a 1 in 1,000 solution of corrosive sublimate; for small bleeding points the smallest size, No. 00, is best. Generally I ligature every small vessel which bleeds and I have never found any trouble result from the presence of 15 to 20 ligatures in the wound.

At this point I would like to draw your attention to a ready method of determining, before the wound is closed, whether all the glandular tissues have been removed. It was recommended by Dr. Stiles, of Edinburgh, and is as follows: The surface of the mass which has been removed is cut off, and soaked for five minutes in a 5 p.c. solution of nitric acid; it is then washed, and if any pieces of epithelial tissue be left they will appear as white and glistening points, the fibrous tissue being swollen, and the fat unaltered. If any of these points be seen some more tissue must be removed at a corresponding place in the wound. This will not delay the operation, as it can be done by an assistant while the axilla is being cleared out.

With regard to cases suitable for operation, I think that some change in the recognised rules ought to be made. In the last edition of "Erichsen's Surgery" (a) we find the following classes of cases described as unsuitable for operation:—

"A. Strongly-marked constitutional cachexy.

"B. Disease in both breasts.

"C. Secondary deposits in internal organs.

"D. Much enlargement of glands under and especially above the clavicle.

"E. Œdema of hand and arm from pressure on the axillary vein.

"F. Adhesions of the tumour to the ribs or intercostal muscles.

"G. Hard, brawny, and infiltrated skin of reddish-brown colour, having a hard leathery feel or a greasy, glazed appearance.

"H. Rapid growth of the tumour in a patient with strong hereditary taint.

"I. An extensively ulcerated and fungating tumour with marked constitutional cachexy."

It is my opinion that most antiseptic surgeons will operate on nearly all these classes of cases; in fact, out of the nine conditions called unfit for operation, I should refuse to operate in two only, namely, the strongly-marked constitutional cachexy, and secondly, the presence of secondary deposits in internal organs.

Cancer of both breasts is certainly not unsuitable for operation; both breasts are usually removed at the same time. A considerable number of cases have been shown at the societies after the operation, and Dennis, of New York, mentions a case which was free from recurrence three years later.

In cases of much enlargement of the glands under and even above the clavicle I should still be disposed to operate, but of course I should feel bound to do a most radical operation. With regard to the glands above the clavicle, it is worthy of note that they increase in size usually at a very slow rate, and therefore do not give very much trouble; also they are difficult to remove, as I found in the case of a lady lately under my care whose primary growth had been removed eighteen months before, and who had a recurrence in the axillary and cervical glands. I removed the recurrence from the axilla, which consisted of the glands between the scapula and thorax, but on attempting to remove those above the clavicle I found I could not do so without opening the pleura, and gave up the attempt. These have not increased in size at all since the operation.

Œdema of the hand and arm from pressure on the axillary vein need not deter one from operating. Although in such a case one would probably find that the glands were adherent to the axillary vein, still it is quite harmless to remove a portion of the vein, as I have pointed out above.

When the tumour is adherent to the intercostal muscles and ribs, the operation, of course, to be satisfactory, must be rather severe, but still I think that it is quite justifiable, although one has to remove portions of some of the ribs and intercostal muscles; he pleura will probably escape injury. In one of Dennis's cases portions of as many as three ribs were removed at the operation, the patient making a good recovery and remaining free from recurrence a year later.

(a) "Erichsen's Surgery," 1888, vol. ii, p. 779.

Infiltration of the skin no longer puts operation out of the question, since after very large amounts have been removed the surface can be covered in with Thiersch's grafts. This condition, therefore, calls for a free operation.

Few surgeons would hesitate to relieve a patient of a rapidly growing tumour, although there was a strong family history of cancer, but such conditions should make one remove the tissues very freely.

There is, however, a class of case where an operation has sometimes been credited with accelerating the course of the disease. I refer to cases of atrophying scirrhus, which perhaps may have existed two or more years before operation, but after amputation have rapidly recurred and proved fatal. It is probable in such cases that as the tumour was very small, the whole breast tissue was not removed, but in such long-standing cases the cancer cells have probably spread a considerable way along the lymphatic channels, so a free operation is necessary, which probably would not be followed by rapid recurrence. But on this point I should be very glad to have the opinion of practitioners who have watched such cases to the end, both without and after operation.

Lastly, there is one point above all others which seems to influence the freedom of recurrence after removal of the breast for cancer, and this is the previous duration of the disease. Thus, in every one of the 30 p.c. of "cures" got by Dennis, the disease had existed less than six months before the operation. It is still a question whether we ought to look upon a recurrence as a fresh cancerous infection, or as an evidence that all the cancer cells have not been removed. For my own part, I strongly believe in the latter theory, chiefly on account of the better results which have followed when a more radical operation is done, as well as on account of the evidence of recent pathological work.

In the above remarks I fear I may appear to have given my own opinions too freely, but I hope that the fact will induce some of the members of the society who have had much experience in the subject to give us the benefit of their work also.

◆

A CASE OF APPENDICITIS,

WITH SOME REMARKS ON THE ÆTIOLOGY OF THE DISEASE. (a)

By E. WEARNE CLARKE, M.D., B.Sc.Edin.

SOME weeks ago Dr. Sinclair White related to this Society a case of relapsing appendicitis of a most interesting character, which was brought to a happy termination in his hands by operative measures. I propose in the first instance to detail shortly a case of appendicitis which not long ago came under my own care, and which is remarkable, both on its own account, and because it forms a very distinct contrast to that case of Dr. Sinclair White's to which I have alluded. It concerns, indeed, a phase of the malady, widely different in histories, its circumstances, and mode of termination, and I venture to relate it the more readily that I believe this subject has not engaged the attention of the Society for some time until the present session.

CASE.—My patient was a lad, aged (at the time of his illness) eleven years, healthy and robust, and with no ailments to chronicle, except a mild attack of scarlet fever some six years before, which had left no legacies behind it. Three days before I saw him he had been playing football, and there was a doubtful account of a blow or kick in the side then received. In any case, on the day after the game he was out of sorts, and complained of pain in the lower part of his abdomen, which was attributed to causes of a kind familiar to his age, and treated accordingly by domestic measures. Next day, however, the pain still persisted, and there were occasional bouts of vomiting. It was at this point that I saw him. I found him in bed complaining of pain in the right iliac region and in the hypogastrium, with tenderness in the same situations, perhaps rather more marked at the last-named point. Over the right iliac fossa the abdominal muscles were somewhat resistant and contracted. No tumour or dulness on percussion was to be made out anywhere. Micturition was painful and difficult, very little urine was being passed, and that little was loaded with urates. There was also rectal tenesmus, the frequent calls to stool being attended with much pain and uneasiness. The tongue was thickly furred, the vomiting frequent; the temperature was 100°, and the pulse 120. The boy was directed to keep his bed absolutely; he had some morphia and hot fomentations, with a restricted diet, and his friends were warned to give him no further aperients. The first few days showed little change, except that the abdominal pain and tenderness extended towards the *left* iliac region, and that the abdomen generally became somewhat distended. The temperature, never above 100°, often stood at 99°, and was often normal. The vomiting, at first very distressing, became by degrees less frequent and finally ceased, and with it the troublesome tenesmus. On the whole then, there was an apparent amelioration, except that the pulse remained quick, 120 to 140, and thready and feeble. The undefined and extended painful area became slowly much less marked, but along with this there was very much more pronounced tenderness in the right iliac fossa, and a sense of deep resistance and tension, at first very ill-defined, began to be experienced there. After pretty frequent and minute examination, a little dulness was detected above and parallel to Poupart's ligament, and this dulness and sense of resistance very gradually became more distinct. The whole of the physical signs, in short, tended to localise themselves in the iliac fossa. By the end of the second week there was a definite enough swelling, the tumour was apparent; and, moreover, one could begin to make out a little fluctuation in it. Also a new feature appeared—a painful swelling behind the angle of the lower jaw on the left side, which presently manifested itself as a genuine parotid bubo, an event not rare in these cases. The little patient began to lose flesh rapidly and to show signs of debility, and he had an irregular and somewhat hectic temperature. I then explained to his parents the position as to operative measures, which I deemed essential, and which I had already urged at an earlier stage. I found them absolutely averse to anything of the kind; whereupon I asked that another opinion should be taken, and Dr. Dyson was selected, who was good enough to promise us his help a little later in the day. An hour or so later on, however, I was summoned urgently, and found the boy sitting up in bed, breathing with extreme rapidity, with cyanosed face and an indescribably anxious look, a pulse so feeble that it could not be counted, and a temperature of 102°. I was told that quite suddenly he had been seized with a coughing, spluttering fit; and, indeed, he was spitting out quantities of a fluid which was chiefly unmistakable pus, and pus with a strong fæcal odour, which was welling up constantly. I could make no examination, I got him rallied somewhat; and shortly afterwards Dr. Dyson and I examined him together, and found dulness over a wide area of the base of his right lung, with bronchial breathing and abundant crepitations. We agreed, of course, that operation was now out of the question, and that the prognosis was of the gravest. For the next twenty-four hours this state of things lasted. At the end of that time another remarkable thing occurred. There was a sudden, free, loose movement of the bowels, followed by a second and third, and these stools contained pus and mucus and a few scybalous masses. I should say that after the first week the bowels had acted naturally, and that the evacuations had been fairly firm in consistence. Coincidently, the swelling in the iliac fossa diminished, and with it the general distension of the lower abdomen. After a few days the distension was gone, and the swelling in the iliac fossa was represented only by a hard lumpy mass, which gradually diminished in size. The temperature, however, remained persistently elevated, the pulse was still rapid, the lung was still consolidated, and the expectoration still contained traces of the same purulent stuff. For two weeks the issue was doubtful, but at last a gradual change for the better occurred. The temperature fell, and at last reached normal limits, expectoration lessened and then disappeared, the pulse became less frequent and stronger, the appetite returned, and the general condition improved; finally the lung very slowly began to clear up. There was a long but uninterrupted convalescence, and for a long time one could make out a hard mass in the iliac fossa, but it also slowly melted away, and the lad returned to his former good condition of health. I had an opportunity of examining him a few weeks ago, nearly two years since his illness, and there now remains not a trace of the mass perceptible.

(a) A Paper read before the Sheffield Medico-Chirurgical Society.

This case is, to my mind, a very typical one of that form of appendicitis which results in a localised suppurative peritonitis; and the termination, by secondary perforation of the abscess into the bowel is quite a common event, so much so that it may be said to constitute the natural method of cure in such cases when left to themselves. There are numbers of similar instances recorded, but it is not quite so clear what happened to the lung. Two alternatives are possible. Either the pus, burrowing behind the ascending colon, perforated the diaphragm and thus gained the pleural cavity and the lung, or we had to deal with a consecutive infective septic pneumonia.

We had, very fortunately, no opportunity of settling the pathological question *de visu*, but I incline to the former supposition. There are recorded cases which at least render it a reasonable enough hypothesis.

Of late a great deal of attention has been paid to the group of symptoms which are comprehended under the name of appendicitis. The use of the term expresses the conviction, which has now, we may say, reached the point of certainty, that the appendix is responsible for the appearance of most of the conditions which we were once accustomed to group under the names of typhlitis, perityphlitis, and paratyphlitis. The history of this affection in recent years affords a remarkable example of what one may term the evolution of pathology. It is not so very long ago since all the phases of the malady were ascribed to various stages of affection of the cæcum itself. Following the authority of Albers, of Bonn, there was supposed to be a stasis of fæcal matters in the cæcum, which set up catarrh, irritation, and ulceration of its mucous lining, which might be propagated through the cæcal walls to its peritoneal investment, and to the parts adjoining. There was further supposed to result an inflammation of an equally supposed retro-cæcal cellular tissue, which might proceed to suppuration. The appendix was mostly left out of account; it was not considered to have anything to do with the matter, and its condition was not usually examined in making an autopsy. If from time to time an authentic perforation of the appendix was discovered and described, it was considered as something apart from the ordinary run of the so-called typhlitis; it was called "fæcal abscess," and was thought a disease of a totally different character. The credit of rescuing the appendix from this ill-deserved obscurity undoubtedly belongs to the abdominal surgeons, notably to Sands, Weir, Bull, Fitz, and many others in America, and Treves among ourselves. With the progress of abdominal surgery intervention came to be solicited in these cases; at first in the graver, then in the less severe. These operations, performed often early in the course of the disease, showed very conclusively that in cases called typhlitis or perityphlitis, the appendix was the site of the primary lesions. The normal anatomy and the pathology of the appendix have since then received minute attention at the hands of many observers, with the result that the cæcum has been relegated to quite a subordinate place; and the pendulum has so swung over that a recent writer (Talamon) says that in order that the clinical signs of the classical typhlitis may appear, the appendix must be affected.

Ætiology.—There are several questions of interest in connection with the causation of this disease. A point of primary importance in this respect is that the human appendix is a functionless organ, and that from an evolutionary standpoint it is (as was recognised by Darwin) an example of retrograde metamorphosis. It represents all that is left in the human subject of the capacious appendices of the herbivora and rodents. Its blood supply is meagre; and while it is frequently congenitally bent or curved on itself, or assumes an abnormal position, it in any case possesses a wide range of movement, and is apt to wander from its normal site and contract adhesions to other far distant viscera. These considerations are sufficient to show that it is an organ, which, *primâ facie*, might be expected to become liable to catarrhal and inflammatory mischief. Histologically, its mucous lining is remarkable for the abundance in it of masses of lymphoid elements similar in structure to the agminate glands of the intestine. It possesses also a few Peyer's patches. Various observers—Bland Sutton and Ransohoff in particular—have remarked the striking analogy which this lymphoid material has to that of the tonsils, and the former author also points out that the inflammatory lesions of the two organs present also a close analogy. This fact, indeed, was observed and referred to nearly ten years ago by Fox, who also pointed out that inflammations of both tonsils and appendix are diseases of early life and apt to occur without obvious cause. The outer layers of the appendix simulate in an incomplete manner, the structure of the muscular coats of the intestine. They are of fibrous tissue, with a varying amount of muscular fibres, arranged circularly and longitudinally, and the organ possesses a certain degree of contractility, with but little extensibility.

Another factor of the greatest importance is the part played in its inflammatory lesions by micro-organisms. The appendix, a sort of back-water of the intestinal tube, becomes a gathering-ground for any organisms it may contain, and under certain conditions a kind of culture-tube. It appears exceedingly likely that when the appendix undergoes certain conditions of obstruction and compression, some species of these micro-organisms multiply in its mucous secretion and in its walls, and presently bring about its ulceration, gangrene, or perforation. The exact species of organisms which bring about these changes vary in different cases. The bacterium coli commune appears very frequently, but the streptococcus pyogenes and the staphylococcus aureus and others have also been observed. These facts are results of the labours of Ruffer, Fränkel, Laruel, Welch, Malvoz, and others. A point of some interest is in what manner these organisms gain access to the intestine. According to Alapi, it seems that pyogenic organisms are killed in the stomach by the normally acid gastric secretion, but that if this secretion be temporarily rendered alkaline they can readily pass into the intestine in an active state. Thus, while the bacterium coli commune seems to play a very active and preponderating part, it is not the exclusive organism found; and in view of the obvious bearing of these points on the pathology of perforations of the intestine at other situations than the appendix, the further development of this subject will be awaited with interest.

But apart from these considerations there is another factor which has received more general attention. It is the part played by foreign bodies. It seems that a celebrated teacher of anatomy used to tell his students that the only function of the appendix was to act as a receptacle for cherry stones. And, indeed, not only cherry stones, but all manner of unconsidered trifles have been found in the appendix—fish bones, tintacks, seeds and stones of fruits, biliary and intestinal calculi, lumbrici, and last, but by no means least, hardened fæcal masses in the shape of scybala. Many of the bodies formerly supposed to be stones or seeds have when more carefully examined by the microscope and chemically, turned out to be fæcal matter, often with a nucleus of extraneous nature, and often too with a coating of phosphatic salts. Such bodies frequently present a strange resemblance to fruit-seeds in shape and hardness. These bodies, of extra- or intra-intestinal origin, have frequently been found from time out of mind, either lying in the ulcerated or perforated appendix, or in the pus of a peri-appendicular abscess.

Of a total of 760 cases collected from various sources, 450 times the presence of a foreign body is expressly noted; and of foreign bodies, scybala are the most numerous. These bodies have been long suspected of playing an important part in the production of the disease, but the exact mechanism was dubious. They were thought to produce catarrhal or other changes by their mere presence, a view which is negatived by the fact that they are often present without producing any bad results. The more recent view is somewhat as follows:—The foreign body slips into the narrow cavity of the appendix, which has at its cæcal extremity a fold of mucous membrane which has received the name of the valve of Gerlach. It becomes impacted, so that the feeble contractions of the appendix are powerless to expel it. If it be a pointed body, pin or fishbone, it may, of course, actually push its pointed part through the appendicular wall. If it is a rounded body, it apparently does little or no harm so long as it does not occlude the appendicular lumen. If it does occlude it, the first result is accumulation of the products of the mucous glands of the appendix, and its consequent distension. This goes on till the feeble circulation is impeded or arrested. Then come into action the microbic tenants of the appendix, which proliferate, attack its defenceless parietes, and bring about their destruction.

The fæcal masses which thus act in so harmful a manner appear very frequently at least to have their origin in defective functional activity of the colon—a sort of chronic colitis showing itself by abnormal dryness or secretion, and more or less atony or irregular contraction, and translated clinically by vague digestive disorders, abdominal uneasiness, diarrhœa, constipation, and the like.

In addition to the obstruction of the appendix by foreign matters from without, it should be noted that a cystic dilatation has been observed, in which from obliteration of the upper part of the canal from some cause not well understood (probably ulceration and subsequent cicatricial contraction) the cavity of the appendix becomes dilated and filled with a milky fluid. This is frequently the condition met with in cases of true relapsing appendicitis.

As to occasional and subordinate causes, the disease is most common in childhood and adolescence, and far more common in the male. It appears certain that the ingestion of excessive or unsuitable diet, cold, and various traumatic causes, such as kicks, blows, and strains, have occasionally determined the outbreak in predisposed persons.

It remains to add that the appendix may be involved in the course of various specific processes, tubercle, typhoid fever, dysentery, cancer, and even, as in one or two instances recorded, actinomycosis, and; that these may thus set up a specific form of appendicitis.

◆

Selected Prescriptions and Therapeutic Notes.

103.—For the Green Diarrhœa of Infants:—

℞ Acidi lactici diluti, ♏iv;
Tinct. limonis, ♏j;
Syr. Simplicis;
Aquæ, āā ℥ij.

M. A teaspoonful thrice daily after suckling.—*The Practitioner.*

104.—A Dressing for Soft Chancres:—

℞ Pulv. camph;
Plumbi acetatis, āā ʒj;
Pulv. amyli, ad ℥j;

M. The chancre should be freely sprinkled with the powder three times a day, and immediately afterwards covered with a piece of cotton wool which has previously been dipped in castor oil.—J. Monroe.

105.—For the Gastralgia of Young Girls at the Age of Puberty:—

℞ Argenti nitratis, gr. j;
Glycerini, ʒiiiss;
Aq. destill, ad ℥vj.

M. A dessertspoonful three times a day.—
Escherich (*La Semaine Medicale*).

106.—Salicylate of Soda has been found of use in the treatment of tetanus, following suppuration of the remains of the umbilical cord in the newly-born. For a child of nine days, about one grain is the dose, administered at intervals of three hours, until relief is obtained.

107.—Useful Gargle for Chronic Pharyngitis:

℞ Salolis, gr. xxxv;
Tinct. myrrhæ, ʒijss;
Sp. vin. recti, ℥jss.

M. Gargle the throat thrice daily with a solution made up of a teaspoonful of the above added to eight ounces of water.—Schmidt.

◆

The London College of Physicians have agreed to the request of the Chelsea Hospital of Women to appoint a representative of the College to serve on a committee to investigate the charges brought against the Hospital by the Medical Officer of Health for Chelsea.

Dr. Henry Pomeroy Truell of Wicklow, has been appointed a Deputy Lieutenant for his County, a distinction which does not often fall to the lot of a medical man.

The Manchester Royal Infirmary has received £50,000 by the will of Mr. Weston, a yarn agent of that city.

Clinical Records.

CASES IN PRIVATE PRACTICE.

By Dr. J. Pearson,

Assistant Medical Officer to the Sheffield Children's Hospital.

Case of Excision of the Shoulder.

Mr. M., a fireman, presented himself at my surgery in April, 1892, complaining of pain in the left shoulder-joint and stiffness. He could only move his arm an inch or so from his side. The patient also complained of loss of flesh. He had previously weighed 11 st., and his weight then was 9 st. 2 lb. He had also a very unhealthy appearance

Previous History.—Whilst attending to his duty as a fireman in January, 1891, he fell off a wall 12 or 13 feet in height, on to his shoulder. He, however, continued at his work. A few weeks afterwards he had aching pains in the joint, and had to go off duty for ten days (that was in May, 1891). He was off duty again in July for a week or two, and his arm was partly ankylosed. He up to this time thought it was rheumatism. The pain continued increasing, and on Sept. 16th he went into the Public Hospital. He was there examined under ether, but left the hospital on October 3rd, before an operation was performed. The patient continued to do light duty until he came to see me on April 8th, 1892.

Condition at that time.—He had very slight movement in the joint, and it was attended with great pain. There was an abscess pointing on the front of arm about 2½ in. below the joint. This was opened and a probe passed in the direction of the shoulder-joint, but did not reveal any dead bone. The sinus continued to discharge unhealthy pus for a few weeks, then another abscess pointed behind about half way down the scapula; this was opened, and an operation suggested, bnt the patient did not agree to have one done until June 28th.

With the assistance of Mr. Pye Smith and Dr. Willey to give ether, I cut down upon the joint and found several loose pieces of bone and the head of humerus quite rough and spiky. The loose pieces were removed and the head well scraped with a raspatory, and the wound stitched up, leaving a drainage tube in. The sinuses were well scraped out. The patient soon began to improve and gain weight; the sinuses, however, did not heal, but the man was free from pain for nearly eight months. I then persuaded him to let me operate again. Mr. France assisted me and Dr. Porter gave ether. I found on cutting down considerable disease, both of the head of the humerus and the glenoid cavity, also the tip of the coronoid process of scapula was rough and bare. There was also a small collection of pus at the back of the head. I this time removed the whole of the head of bone and the tip of coronoid, and scraped out the glenoid cavity and put in a drainage tube back and front. The patient made a rapid recovery, and was doing light duty as a policeman in two months, and the sinuses quite healed. He has now been able to do ordinary fireman's duty for six months or more, and has gained 2 st. in weight. He can lift a very considerable weight with the arm, but cannot extend it laterally quite to a right angle with his body.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, April 4th, 1894.

The President, Dr. G. E. Herman, in the Chair.

Dr. Amand Routh brought forward three cases in which

VAGINAL CYSTS WERE CO-EXISTENT WITH THE PAR-OVARIAN CYSTS,

which appeared to the author to have an important bearing on a moot point in female anatomy and homotology. This paper will be found in another column. In the discussion that followed,

Mr. Alban Doran pointed out that, though cysts were tolerably common in the upper, horizontal portion of Gartner's duct, *i.e.*, the part enclosed in the broad ligament, they were very rare in the lower part, in fact, vaginal cysts of all kinds were excessively rare. This, however, was, he admitted, only negative evidence, and did not militate strongly against the correctness of the author's assumption in regard to the course of this duct. Fischel had succeeded in tracing the duct into the substance of the cervix, where it seemed to double back on itself. From a practical point of view, he remarked that cysts of the vagina required to be dealt with very cautiously on account of their anatomical relations. He referred to a case in which a vaginal cyst had attained very considerable dimensions, and was attributed to distension of Cowper's gland, but he did not believe this to be the case. He insisted that these cysts must be distinguished from cysts of the vulvo-vaginal glands which, though surrounded by large vessels, were nevertheless accessible enough in the event of hæmorrhage.

Mr. Bland Sutton said he was disposed to accept the author's conclusion that this cyst originated in a patent Gartner's duct, but he pointed out that it was just within the reach of possibility that the duct in question might have been an abnormally placed ureter, for it was, he said, well known that women sometimes possessed an accessory ureter which in a case under his own observation, opened into the urethra near the neck of the bladder. This subject interested him because it was one of the first regions which he explored in his search for the potential causes of cyst-formation in the female. He had at that time examined a large number, about 70, of uteri from cows and sows, and in these he found Gartner's duct running along the ventral wall of the uterine cornua usually losing itself in the vaginal wall. The difficulty in deciding the exact termination of the duct was doubtless owing to the fact that the lower part was the first to become obliterated, and it was consequently rare to get a persistent duct, the termination of which could be traced to the vagina. The early disappearance of the lower part of Gartner's duct also explained in a great measure the comparative rarity of cysts arising in this portion compared with the frequency of tumours of the parovarium. Cysts arose more frequently in the middle portion than one was apt to suppose, but when these attained a large size, they closely simulated a parovarian cyst, with which they were usually classed. It was the co-existence of the two cysts that made the author's case particularly valuable.

Dr. Leith Napier referred to a case which seemed to have some bearing on the subject under discussion. The patient, a young married woman who had had syphilis and probably gonorrhœa, presented a cyst the size of an orange in the right side of the pelvis with a good deal of thickening on the left side. On three occasions the menstrual period had been associated with an attack of peritonitis, placing her life in danger. On opening the abdomen, in the expectation of finding a tubo-ovarian cyst, he found, amidst evidences of intense peritonitis, a right broad ligament cyst, partly of inflammatory nature, and on the left, a smaller cyst about 5 cm. in diameter, inside of which they found a small purulent cyst as large as a pigeon's egg. He asked the author whether he could explain this curious formation on his hypothesis.

Dr. Herbert Spencer pointed out that the middle part of Gartner's duct had been traced to the uterus and along the cervix to the vagina which he imagined was the usual course, that is to say in the outer part of the uterine wall and not in the broad ligament. He had in his possession a preparation of a fœtus at about the seventh month in which the duct, somewhat dilated, could easily be seen with the naked eye, and growing from the wall was a little tuft of papillomatous formation. It was generally concluded that the lining membrane of Gartner's duct was very apt to give rise to a papillomatous growth. The microscopical appearances of Gartner's and Skene's ducts were quite different, the latter being composed of glandular epithelium with numerous recesses, in fact its structure was altogether peculiar.

Dr. Griffith observed that Skene himself did not describe the duct thus, and he asked how the last speaker knew for certain that he was really examining a Skene's duct. He and others had on several occasions done their best to find a structure corresponding to that described by Skene but their efforts had been in vain. He pointed out that the mucous membrane of the female urethra was remarkable for the great number of depressions and crypts which in some parts extended even beyond the muscular coat, and he asked how the last speaker could be sure that he was not examining one of these depressions. He thought it was a pity to assume, as the author had done, that these points were definitely settled, for this was far from being the case.

Dr. J. **Oliver** dissented from the view that vaginal cysts were so very rare, seeing that he had met with six of them within a few months, two of which originated in Gartner's duct, both being on the right side of the vagina, extending from its roof towards the anterior wall, to close upon the remnants of the hymen. One of them contained three ounces, and the other, six ounces of a fluid of low specific gravity resembling that met with in parovarian cysts. The vaginal cysts, however, might contain any kind of fluid, in one instance it was treacly, probably owing to hæmorrhage into the cyst. He agreed that many vaginal cysts originated in Gartner's duct.

Dr. A. **Routh**, in reply, pointed out that no communication had as yet been shown to exist between Gartner's ducts and Max Schuller's glands.

◆

LIVERPOOL MEDICAL SOCIETY.

Meeting held Thursday, March 29th.

The President, Mr. C. **Puzey**, in the Chair.

REGISTRATION OF PLUMBERS.

Dr. **Steeves** moved the following resolution, which was seconded by Dr. Carter, and carried unanimously, "That the members of the Liverpool Medical Institution, fully recognising the great importance of an efficient system of Registration for Plumbers, are of opinion that such registration should, without delay, be placed on a firm legal basis by Act of Parliament;" and that this be sent as a memorial to the President of the Local Government Board, Sir Walter Foster, M.P., and Mr. Lees Knowles, M.P.

CASES.

Operation for Intestinal Obstruction.—Mr. **Robert Jones** related a case where he operated for intestinal obstruction, the obstruction having lasted twelve days. There was considerable distension, but a median incision was made and the cæcum found collapsed. He also felt empty small intestine in the pelvis. The obstruction was placed in the shape of a band about three-quarters of an inch broad, which compressed the ileum, producing complete blockage. The band was severed, and fæcal vomiting, which had been constant up to the operation, quite ceased, and the patient rapidly convalesced.

Hydatid of the Liver.—Mr. **Robert Jones** also related a case of hydatid of the liver, which he incised and stitched by a double row of sutures to the abdominal wall. He removed 120 ounces of fluid. The patient recovered.

Idiopathic Tetanus.—Dr. **Archer** related a case of idiopathic tetanus. There was no history of wounds or injury. It was not a typical example of the disease, as the two most distinguishing features viz., trismus and opisthotonos, were entirely wanting. However, Dr. Archer submitted that the other spasmodic manifestations, together with the history were quite sufficient to justify a diagnosis of tetanus being made.

Dr. **Glynn** asked Dr. Archer if it was not possible that his patient had been inoculated through some small and unrecognised wound. He referred to certain cases of tetanus that had come under his notice where the specific poison of tetanus appeared to have been introduced through slight abrasion or wounds—one, a case of ingrowing toe-nail in a greengrocer who walked about his shop wearing worn-out slippers, and probably became inoculated with the organism of tetanus conveyed in the earth brought with potatoes and other vegetables; another, a case where the specific poison appeared to have been introduced through a slight abrasion of the knee, and another where it entered the blood through a small cut on the finger.

Dr. **Bradshaw** pointed out some features in Dr. Archer's case that were very unusual in idiopathic tetanus, namely, the early fatal issue, the difficulty in swallowing, and above all, the absence of trismus. The case related reminded him forcibly of the symptoms of hydrophobia.

Dr. **Alexander** showed a specimen "Cast of Mucous Membrane of Bladder."

Dr. **Hope** read a paper on

INSANITARY PROPERTY AND ARTISANS' DWELLINGS.

The nature of the property specifically dealt with as insanitary consists of three-roomed, back-to-back, and side-to-side, houses arranged in closely congested courts, being without open space of any kind, and having the water-closet and ash-pit accommodation and the water supply variously disposed in the court; the entrance to the court being narrow, and frequently built over, and so converted into a tunnel. Many of these courts were constructed prior to 1847, and are in a ruinous condition. The existence of this class of property is owing to the rapid development of the city in the earlier years of the century, at a time when no control was exercised over the erection of houses. The construction of back and back property was not put an end to till the year 1864. From that year, measures had been in gradual progress for dealing with the existing evil. A large insanitary area was dealt with under Cross's Act, and the Victoria Buildings were erected on the site. These were opened in 1883. Since 1884, 2,860 houses of the type described have been demolished, and various suitable dwellings erected on their site. Hitherto the "Housing of the Working Classes Act" of 1890 has not been put into force, as it is generally considered more convenient to act under the "Liverpool Sanitary Amendment Act," and its various amendments. A comparison was made between the two Acts by Dr. Hope, and their various advantages and disadvantages were closely criticised, and the mode of procedure under each was set forth. The death-rate, it was stated, in areas which had been demolished, had for a series of years ranged between 40 and 60 per 1,000, while in the new cottages or blocks the mortality during the last three years had approximated only to 22 per 1,000. Up to the end of 1893 a total sum of upwards of £265,000 had been spent by the Corporation in demolition of houses unfit for human habitation, a sum which does not include the cost of the dwellings erected on the cleared areas. The work must necessarily progress slowly, as reconstruction must accompany demolition. Dr. Hope expressed an opinion in favour of the erection of cottages rather than large blocks of four or five storey dwellings.

Dr. **Steeves** said he had once to take action under the "Artisan's Building Act" in the Toxteth Park district, where the demolition of the property had to be undertaken. In this case the ventilation and light were bad, houses back to back, dilapidated and defective walls, floors, and ceilings, and the absence of all sanitary conveniences.

Dr. **Moore**, referring to the objection that the new dwellings built upon clearer areas do not become inhabited by the same class of people as those displaced, pointed out that such consideration ought not to stay the work of sanitary progress.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Thursday, March 15th, 1894.

The President, Mr. **Richard Favell**, M.R.C.S., in the Chair.

Dr. **Hargreaves** brought forward a case of

SERO-CYST OF MAMMA.

The patient, Mrs. R., æt. 51, ceased menstruating six years ago; has a family of children, some upgrown. Fourteen months ago her son playfully took hold of her under each arm from behind, when she complained of severe pain in right breast; shortly after perceived a small lump deep in the breast, and two months after injury began to apply ung. pot. iod. I saw the patient four months ago, when I could feel a lump in the body of the breast, and applied emplas. belladon., but in the beginning of January the tumour had become superficial and fluctuating. When incised there issued dark straw-coloured serous fluid (quite thin and limpid). The breast was treated with stimulating applications and pressure, but the wound formed a fungating excrescence of soft spongy granulations from which issued serous fluid to the extent of about 2 oz. a day. The tumour with excrescence is situated two inches above and to the outer side of right nipple; no retraction of nipple, and no enlarged axillary glands. In removing tumour the elliptical incisions were extended beyond tumour to include the nipple. The tumour occupied the whole depth of the breast, to the sheath of pectoral muscle, the fibres of which were exposed in the removal. On examination after removal the cyst is found to be the size of a hen's egg, well defined with membrane and containing softened purulent sebaceous matter and no other cyst or morbid growth was found.

Mr. E. E. **Waters** introduced a case of

HYPERIDROSIS AND HEMIANÆSTHESIA.

Patient, a man, æt. 30, attributes his symptoms to a fall received three years ago, in which he injured his head. Since that date he has perspired freely on that side, and also been anæsthetic. There are no subjective sensory phenomena. There is complete anæsthesia on the left side of the body, sharply bounded by the middle line. Reaction to heat and cold is indefinite. The special senses are affected. The field of vision of the left eye is contracted, but the pupils react to light and accommodation. The patient is deaf on the affected side, and cannot taste with that half of the tongue. All the reflexes—organic, tendon, and superficial—are present on both sides. The left half of the body is constantly moist with perspiration, which becomes very marked on the least exertion.

Dr. **Pearson** gave particulars of a case in which he excised the shoulder of a man the victim of an accident. The details of this case will be found in another column under the heading of "Clinical Records."

CASE OF DENTAL REPLANTATION.

Mr. **Frank Harrison** showed a coryliser and read the notes of a case of dental replantation. A central upper incisor which had been knocked out and immediately replaced at the age of 10 was removed fifteen years later by Mr. Harrison for æsthetic reasons. The general aspect was that of a healthy tooth, and strange to say, the central cavity contained perfectly normal healthy pulp.

The President and Dr. Martin made remarks.

Dr. **Gwynne** read the notes of a case of embolism of the pulmonary artery.

The President, Mr. Atkin, Dr. Porter, Dr. Helm, Mr. West Jones, Dr. Hargreaves, and Dr. Sinclair White made remarks.

Dr. **Wearne Clarke** read a paper on "Appendicitis," which will be found in another column.

The President, Dr. Gwynne, and Dr. Sinclair White discussed the paper.

Dr. **Helm** showed a syringe that could be readily and effectively sterilised, with which he had been injecting Brown-Séquard's fluid for the palliative treatment of a case of cancer of the tongue too advanced for operative measures.

◆

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Meeting held April 6th.

Dr. **Donald Hood**, President, in the chair.

Mr. C. **Mallet Bluett** showed a foreign body, a circular disc about 1¼ inches across, and passed per rectum.

Mr. C. M. **Yearsley**.—Fibroma of ovary.

Dr. H. **Wilson**.—A case showing enlargement above the hygomas.

AMPUTATION OF THE BREAST FOR CANCER.

Mr. L. A. **Bidwell** read a paper on the above subject, which will be found in another column. In the discussion which followed,

Mr. **Jessett** agreed with the paper in its entirety, except as to incision, liking transverse incisions in all cases.

Mr. **Keetley** complimented the author, mentioning his predilection for the rectangular position in extensive operations likely to lead to much cicatricial contraction.

Mr. **Bowreman Jessett** read a paper on the

TREATMENT OF ADVANCED CASES OF CANCER OF THE UTERUS.

The cases alluded to were those too advanced for removal of the uterus. In those involving surrounding organs, the application of chromic acid, one part to four of water, was advised with iodine water douche and morphia and belladonna suppositories. In those not so far involved, but yet past extirpation, the whole interior of the organ is thoroughly scraped by the author with his own instrument devised for the purpose, and the cavity is plugged with wool permeated with zinc chloride. This is removed in a few days, and in seven to ten days the slough formed of practically the whole uterus comes away. Illustrative cases were then read.

Dr. **Schacht** inquired if Mr. Jessett knew how far the subperitoneal uterine tissue was removed?

Dr. **Rol** asked if there was any trouble in removing the plugs.

Mr. **Bidwell** remarked that the post-mortem on a patient after the separation of the slough would settle the query raised by Dr. Schacht.

Mr. **Jessett** replied briefly, stating that he had not lost a patient under this treatment.

◆

CATHOLIC UNIVERSITY MEDICAL SCHOOL MEDICAL AND SCIENTIFIC SOCIETY.

Meeting held Monday, March 12th.

The Vice-President, Dr. **Roche**, in the Chair.

Mr. **Coyle** showed amyloid liver, spleen, kidney, supra-renal and intestine.

Dr. **McWeeney** showed the viscera from a case of an elderly woman who had been a patient under Dr. Redmond, in the Mater Hospital, and in whom there was found *post-mortem* an enormous gastric ulcer, about five inches in circumference, which had destroyed the wall of the stomach, the left lobe of the liver being laid bare in front, and the pancreas behind; the ulceration had apparently become stationary, and death was immediately due to œdema of the lungs, consequent upon atrophic and fatty heart. The other conditions found at the autopsy were universally adherent pericardium, pulmonary tuberculosis, with cavities in both apices, with large white kidneys. The exhibitor made some remarks on the causation of gastric ulcer.

Dr. **Redmond** gave a short account of the clinical history of the case.

Dr. **Joyce** showed an aneurism of the abdominal aorta. The man from whom it had been removed was under treatment four years ago in the Whitworth hospital. He then complained of persistent constipation, and great pain in the abdomen. For a long time it was believed the trouble arose from scybala in the colon, but no bruit was heard, and aneurism diagnosed. The aneurism burst about the end of February. At the autopsy the heart was normal; the aneurism pressed on the colon and liver, thus accounting for the pain and constipation.

The **Vice-President** made some remarks on the great tendency of abdominal aneurisms to be latent.

Mr. **Roughan** read a paper on

SUPRAPUBIC CYSTOTOMY.

On the 3rd of February, Mr. McArdle performed this operation, removing two projecting lips of prostatic tissue and a ridge which projected into the bladder in front of a sac which had contained a large encysted stone. Hæmorrhage was successfully treated by tampooning with iodoform gauze. The bladder was drained by a tube adopted by Mr. McArdle on the suggestion of Prof. Birmingham. It consists of two limbs bent at right angles; the limb which is introduced into the bladder rests almost on a level with the internal urinary meatus. Mr. Roughan protested against the inaccuracies of the diagram of the surgical text-books which placed the internal urinary meatus deep in the pelvis, while frozen sections had shown it to be on a level with the *upper* margin of the symphysis. Petersen's bag had proved useless and cumbersome in these operations on the prostate and trigone, while digital support in the rectum had proved extremely valuable.

Dr. **McArdle** explained that the tube might be used as a permanent drain, being connected with a bottle in the pocket of the patient. The tube had proved an almost perfect drain.

Dr. BYRNE said the ordinary drainage tube is nothing but an ornament. He had found that with them it was necessary to constantly change the dressings, owing to the extravasation of urine.

Dr. MCWEENEY read a paper on a case of

LEUKÆMIA,

for permission to study which he was indebted to Dr. Boyd, in whose ward it had occurred in the Mater Misericordiæ Hospital. The patient was a middle-aged farmer, and the disease was of the spleno-medullary type. When first examined the red blood discs were 67 per cent. of the normal, and the relation between them and the white cells about 8 to 1. Under treatment the proportion improved to 1 in 20, the Eosinophyl cells were greatly increased, and enormous myelocytes with and without Ehrlich's granules were very numerous. Neutrophil granulations were abundantly present, and nucleated red blood cells were to be found in each field, but he had been unable hitherto to demonstrate satisfactorily Ehrlich's group of granulations. The significance of the various morphological changes in this disease was discussed, and allusion was made to the metachromatism displayed by the nuclei of the nucleated red blood corpuscles as compared with those of the leucocytes; certain appearances were also found in this case pointing to the extrusion of the nucleus from the nucleated red cells, and the occurrence in the circulating blood of free nuclei apparently belonging to those elements seemed to point in the same direction. In conclusion, the share taken by the bone-marrow in the production of the above changes was discussed and a brief account given of the literature of the subject.

PARIS, April 7th.

INFANTILE ECZEMA.

DR. MARFAN gave an interesting clinical lecture on infantile eczema a few days ago at the Children's Hospital, of which I give a brief summary :—

The different varieties of infantile eczema might be classed under two heads, eczema seborrhœic and dry eczema in disseminated patches.

The former commences almost always on the head, and is in general preceded by crusts, consisting of yellowish greasy squames so frequently to be met with in children. The eczema manifests itself by the apparition of inflammatory phenomena on subjacent skin; beneath and around the crusts is seen redness and a marked tension of the skin accompanied by pruritis, and later on a characteristic humidity. But the affection spreads, first over the whole scalp, then on the temples, the forehead, the eyebrows, the cheeks, and the ear, and above all in the reto-auricular furrow, where it is red, shining, and wet. Sometimes it descends to the neck, where it creates very painful fissures. But one of the chief characteristics of this kind of eczema is that it generally respects the region of the eyes, the nose, and the mouth. The children affected with this variety are generally very large and fat, and present frequently intertrigo in the folds of the skin about the legs. The malady always appears in the first year, and generally in the third or fourth month; it frequently disappears at the time of weaning, but sometimes persists into the third or fourth year. However, at that period it becomes modified, the scalp cleans off, but patches of eczema appear on other parts up to then untouched, and further on an eczematous disposition similar to that seen in the adult persists for many years.

In the second variety (the dry eczema) the scalp is respected. It developes in the form of patches, small, round, or irregular; the skin is red and slightly infl[illegible] covered with small crusts; erosions or fissures are frequently seen on the surface. The eruption is generally observed on the cheeks and on the forehead; it can be seen also behind the ear, around the nose and mouth, on the neck, wrists, hands, abdomen (in the umbilical region), on the back and legs.

The children who present this variety are not of the florid, healthy aspect as those affected with the first variety; they are often emaciated and cachectic; the abdomen always voluminous. The malady is essentially chronic and excites a predisposition to eczema as observed in the adult.

As to the etiology, four principal factors are supposed to play an important *rôle:* Defective nutrition and digestive troubles as a consequence, dentition, heredity, neuro-arthritic, parasitism.

The infants affected with seborrhœic eczema are generally nursed; more rarely they have a mixed diet. The mother in general observes no fixed rules in the feeding of the child; at any and every hour, according to the disposition, the infant was fed and over-fed.

The dry eczema is seen in children brought up on the bottle; the milk is generally of a bad quality, the bottle seldom properly cleaned, and chronic gastro-intestinal dyspepsia is the result.

Dentition has doubtless some influence in the production of both forms of eczema, but it is as yet ill-defined, while heredity has but a predisposing effect. As to parasitism, to which Unna attributed so much importance, there is every reason to believe that it has but a secondary influence.

As regards the treatment, M. Marfan recommended, if the child be nursed, that the hours of feeding be regulated, every two hours during the day, and only twice during the night. The diet of the nurse should be also attended to—no pork, salt fish, nor coffee allowed, and but a moderate quantity of wine or beer. He gives half a grain of calomel once a week, and orders the head to be washed with a three per cent. solution of boric acid and poulticed with potato flour for two or three days. At the end of that time the following ointment is applied :—

Oxide of zinc, ʒj ;
Sulphur, xx grs. ;
Lanoline, } ℥ss.
Vaseline, }

In the case of dry eczema, the gastro-intestinal trouble should be attended to by the administration of salicylate of bismuth of benzonaphthol, and a pomade as follows ordered :—

Oxide of zinc, ʒj ;
Starch, ʒj ;
Salicylic acid, ii grs. ;
Vaseline, } ℥ss.
Lanoline, }

RUPTURE OF THE KIDNEY.

M. Marchand related an interesting case of rupture of the renal organ at the meeting of the Société de Chirurgie. A man, æt. 37, was thrown out of a carriage on the sidewalk, the edge of the kerbstone striking the region of the left kidney. Extreme pain was immediately felt, and the doctor who was sent for diagnosed, from the high temperature, thready pulse and collapse, a rupture of some organ. The following day retention of urine set in, and when the catheter was passed a quantity of blood was drawn off. This hæmaturia last two days. M. Marchand was called in on the fourth day, and found the condition of the patient as follows:—The abdomen considerably distended, with great tenderness and vomiting; a large painful swelling in the lumbar region on the left side; considerable ecchymosis in the inguinal region extending to the root of the penis. In presence of these symptoms he did not hesitate to diagnose rupture of the kidney, and proposed immediate interference, which was accepted. A long lumbar incision was made, cutting through the muscles to the aponeurosis, which was found greatly injected with blood. As soon as it was perforated, a stream of blood flowed out, mingled with clots. The cavity was cleaned out, and when the kidney was exposed M. Marchand found it divided into two fragments by a very large rent. Both portions were removed by the usual method followed in nephrectomy, and the patient fully recovered in three weeks.

Germany.

[FROM OUR OWN CORRESPONDENT.]

BERLIN, April 7th.

CARCINOMA OF GALL-BLADDER.

AT the meeting of the Hufelandsche Gesellschaft, Hr. Saalfeld showed a man, æt. 43, who first came under treatment in May, 1893, with icterus and itching of the skin. The symptoms disappeared in hospital, but returned not long afterwards. At the close of last year he came under the speaker's care with jaundice and itching. There was firm resistance in the right lobe of the liver, which moved on respiration, when it was discovered also that there was a tumour in the region of the stomach and some tumours on the skin. The first thought was of echinococci of the skin, but examination of a portion of the skin, revealed typical carcinoma. Treatment had hitherto led to no result, and only some of the symptoms could be relieved. The patient was losing flesh. The jaundice probably depended on a primary carcinoma of the gall-bladder. The hydrochloric acid of the stomach was much diminished.

The speaker showed a second case, one of cancroid of the left external canthus. The character of the affection was not so markedly pronounced that there could be no doubt as to the diagnosis. One might take it to be a case of lupus, or even of syphilis, either gummatous or ulcerative. Glass pressure showed absolutely no nodules, and the colour was entirely different from that of gumma.

Hr. Liebreich then showed his apparatus for glass pressure, which he had substituted for the simple object glass first used, and which was dangerous for both examiner and examinee. By means of it, small and otherwise scarcely noticeable formations were easily recognisable to the naked eye.

In a paper on the employment of iron, Hr. Langgard gave it as his opinion that the form in which it was introduced into the stomach was indifferent; that the resorption varied, and that this variation depended on causes we were not able to explain; that as regarded its action, its property of blood-making, and also its astringent and tonic influence on the mucous membrane of the digestive tract, were to be taken into account.

The Operating Theatres.

LONDON HOSPITAL.

EXTRA-PERITONEAL TUBERCULAR GLANDS.—PROBABLE DISEASE OF THE CÆCUM.—Mr. TREVES operated on a young man, æt. 19, who had been sent into the hospital with a diagnosis of typhlitis; he had suffered for nine months from pain which was indefinite even to the patient; this pain had mostly been about the epigastric region (which, as the surgeon remarked, is the most common seat of pain in abdominal cases). After a little time this became localised on the right side, there was no peritonitis and no vomiting, but diarrhœa was present with clay-coloured motions. The patient had been in bed for six months undergoing rigid diet. On examination the belly was found to be flat with a lump on the right side which had been talked of as appendicitis; it certainly was in the region of the cæcum and there was a feeling of resistance, but Mr. Treves thought the lump was probably glandular, but as he remarked, it was very difficult to say what it really was. He cut down on to the cæcum, saying he had to be very careful, as the bowel might be adherent to the peritoneum. He cut out some extra-peritoneal tubercular glands, remarking that he did not feel inclined to follow the chain of glands which went down into the pelvis. He pointed out that it was a good specimen of tubercular peritoneum, showing trouble inside the bowel; it was evidently a case of much thickened cæcum with a mass of thickened omentum over it; probably, he remarked, if the cæcum were opened tubercular ulcers would be found on the inside. The peritoneum was first sewn up, then the skin, the peritoneum being sewn first in order to obviate any chance of ventral hernia, which would be very liable to occur in this situation, owing to the gravitation of the intestines. Mr. Treves said that the rest of the parts could not be touched after the removal of a portion of the glands, but probably the mere opening of the abdomen would put a stop to this crude form of tuberculosis.

PYONEPHROSIS—NEPHRECTOMY NOT POSSIBLE OWING TO EXTENSIVE ADHESIONS.—The same surgeon operated on a middle-aged woman, the subject of an enlarged right kidney and pus in the urine. Mr. Treves commented on the difficulty of performing nephrectomy in such a case owing to the proximity of the vena cava. He began by making an incision through a much-thickened right linea semilunaris; he enlarged the opening several times to get clear of the colon and of the liver, and came down on a mass adherent to the liver and to the gall bladder. What this was he was not at first quite certain; it dragged the liver down, and the adhesions were very dense, like leather, but after snipping through a few of the latter he found the mass to be really the kidney; in doing this he came down on the vena cava, to which the tumour was also adherent, as also to the duodenum. In such a case Mr. Treves said he thought discretion the better part of valour, and that it was almost impossible to take the kidney away, as the division of the adhesions would give rise to a lot of hæmorrhage; he considered, therefore, the best plan was to cut down in the loin, open the kidney, let out the pus and drain. This he proceeded to do: when he reached the kidney through this opening he remarked that unfortunately he had come down on the healthy part of the organ, so that he had to then cut through the whole thickness of the kidney to get at the collection of the pus; this latter on being reached by a long knife was found to be considerable. No stone was felt. A gauze drain was left in. The tumour at the abdominal incision was then, of course, found to be collapsed. This wound was sewn up as a whole, no separate stitches being put in the peritoneum, as a ventral hernia was not to be feared in this situation. Mr. Treves said he was sure he had done the right thing in this case, as it would have been bad surgery to have attempted a removal. He said the question might be asked : Why not open the kidney in the loin at once in these cases ? In answer to this he thought the proceeding was disadvantageous, as a pyonephritic kidney was a pus-producing cavity which it was much better if possible to take away by abdominal nephrectomy ; this he considered could always easily be done on the left side, but on the right he thought the surgeon should always be prepared to hold his hand.

MIDDLESEX HOSPITAL.

LAPAROTOMY FOR EXTRA-UTERINE GESTATION.—Dr. WM. DUNCAN operated on a woman, æt. 34, who had had three children, the last being born three years ago. Since then the catamenia had recurred regularly until five months ago ; she then missed one period. At the date of the next she had a sanious discharge which continued more or less up to the time of operation. Four months ago, whilst in bed, she was suddenly seized with pain in the hypogastrium and fainting, which latter lasted ten minutes. She then got up, and was again seized with fainting. She was kept in bed until her admission to the hospital, when it was found that she had an irregular swelling in the lower abdomen ; this on the right side reached half-way up to the umbilicus, whilst on the left side it was more defined, and felt like a slightly enlarged uterus. Auscultation revealed nothing. There was very slight secretion in the breasts. Per vaginam the os uteri was found to be patulous and pushed forwards and upwards behind the symphysis pubis by a rounded swelling which filled up Douglas's pouch and depressed the vaginal roof. Dr. Duncan diagnosed an extra-uterine gestation, which was probably in the first instance tubal, that when the patient had the attack of fainting the tube ruptured between the layers of the broad ligament where the fœtus was now developing. On opening the abdomen in the middle line by an incision extending from just below the umbilicus to the pubes, the placenta at once appeared in view over the whole surface of the tumour with the exception of a small space at its upper part. An opening was made in this space, when a lot of amniotic fluid gushed out. Dr. Duncan then inserted two fingers through the opening, seized the feet, and and extracted the fœtus. During the extraction of head the opening was torn, causing a free bleeding from the placenta ; this was stopped by large forceps, but on attempting to stitch the edge of the sac to the parietal peritoneum some more of the placenta became detached with furious hæmorrhage from the deeper part of the sac, so that the operator decided to at once remove the whole of the placenta ; this was done whilst the abdominal aorta was compressed by Mr. Hulke. The detachment of the placenta took only about a minute, and the amount of blood lost altogether was not more than many women lose at an ordinary confinement. The sac was now tightly packed from below upwards with iodoform gauze (in all nine yards were used) ; no further oozing took place. The edges of the sac were carefully sewn to the parietal peritoneum at the lower part of the abdominal incision ; the upper part of the wound was sutured in the usual manner and the whole dressed with iodoform gauze. The operation lasted about an hour and a half. Dr. Duncan pointed out that the fact of the placenta being all over the front of the tumour made it impossible to extract the fœtus without tearing the placenta. He remarked that the severe hæmorrhage which occurred made him adopt the method recommended by some operators of removing the placenta at the time of operation instead of leaving it to separate by disintegration as he had at first intended. The care with which the placenta was removed and the comparatively small amount of blood lost, owing in a great measure to the effective manner in which the aorta was compressed, made him feel disposed to adopt the same procedure in any future similar case.

WEDNESDAY, APRIL 11, 1894.

THE INTERNATIONAL MEDICAL CONGRESS AT ROME.

THE triennial meeting of medical men of all nations known as the International Medical Congress has on the last two or three occasions been a conspicuous success. Congresses are the fashion of the period ; and it cannot be disputed that they serve a useful purpose both in the dissemination of knowledge as well as in the promotion of international courtesies among scientific men. In this respect the *réunion* at Rome just held must be regarded as having fulfilled its mission to an eminent degree. When men of "light and learning" meet together and discuss questions of great import to the profession and the public, it must be that the world becomes richer from the diffusion of the knowledge thus brought about. It is, perhaps, too early yet to speak of the true scientific value of the Congress just concluded. To attempt to make any estimate of the scientific results achieved would at present be premature. The attention of those who took part in the meeting is probably still fully occupied in the recollection of the many wondrous sights and scenes, the hospitality of their hosts, and the enjoyment of which the visit to Rome was generally productive. Until the subsidence of all this, shall we say, not unnatural excitement, it is scarcely possible to expect those best qualified to judge to proclaim their opinion of the value of the Congress from a scientific point of view. It may, however, be taken as a fairly sound axiom that whatever is done at these international medical congresses by the readers of papers and others is something worthy of the occasion. For the most part the "contributors," as our Italian *confrères* call them, are not anxious to perform unless they have something novel—something of their best to bring forward. In this respect these international congresses markedly differ from those professional *réunions* which are not of an international character. At these latter, the effort is not so much to do something good, but rather at any price to do *something.* Self-advertisement, we fear, is the sole incentive to the performance of many readers of papers in these cases, and there is no doubt that generally the mere fact of doing "something" continually proves a very profitable undertaking—indirectly. But everyone who undertakes to perform before an international audience of his *confrères* doubtless makes up his mind beforehand that his communication must be the best that he can produce. Here the consideration of his reputation has to be given the first place; consequently, it happens that these congresses become the medium of the publication to the world of medicine of the results of much valuable original work. So far, a mere fraction only of the papers read at the Congress in Rome has reached this country: according to the general secretary, the total number of contributions equalled 2,700; it must thus appear plain that it will be a long time yet before the main features of the proceedings will be available for publication. But of the public addresses a great deal can be said. From the President's (Professor Guido Baccelli), which was delivered in Latin, much that was excellent in thought and expression could be gathered; moreover, the charm of oratory seems to have rendered its delivery doubly attractive to those who could appreciate the meaning of its flowing periods. Again, a very notable performance was that of Professor Virchow, whose address on "The Influence of Morgagni on Anatomical Thought" recalls somewhat his Croonian Lecture before the Royal Society two years ago, in which he called attention to the work of a "forgotten English anatomist," Edward Glisson. The short abstract of this address, published in the official journal of the Congress, shows how thoroughly Virchow had mastered his subject, and how much reason he had for concluding that Morgagni taught us to think anatomically, and thus became entitled to the distinction of being regarded as the founder of modern pathology.

◆

THE MEDICAL DEFENCE UNION.

It is matter of common knowledge that the conduct of affairs of the Medical Defence Union has given rise to a considerable feeling of dissatisfaction among members of that body. Matters have now been brought to a crisis by the resignation of Dr. Leslie Phillips, the provincial secretary, and by the withdrawal of the Council from the appeal in the action brought against the Union by Dr. Bloxham. Readers may be reminded that this litigation arose out of a partnership dispute between Dr. Collie and Dr. Bloxham. As already reported in our columns, both these gentlemen were members of the Defence Union, and each of them invoked the aid of the Society. One of the litigants, Dr. Bloxham, applied to the provincial secretary, and was dissuaded from further expectation of obtaining help on the ground that such cases were not within the province of the Union. The other litigant, however, sent in his application to the London secretary, by whom it was laid before the Council and accepted. This decision was naturally looked upon by Dr. Bloxham as likely to prejudice his case materially. He accordingly applied for an injunction to restrain the Union from supporting Dr. Collie in either of the cross actions then pending. His application, on appeal, has been completely successful, as the Defence Union had to retire from the case, and allow a perpetual injunction to be entered against them. Before this conclusion was arrived at the Judges of the Supreme Court strongly insisted that the action of the Council afforded that unwarrantable and judicious interference known to the English law as maintenance. The offence is a serious one, and must be considered apart from the merits of the original dispute, which, indeed, were not disclosed at the trial, and are officially known only to members of the Council of the Union. The future policy of the Society, however, must be determined on abstract principles, and not on the ultimate issues of the private quarrels of Drs. Bloxham and Collie. It is obvious that the Defence Union will have to arrive at a clear conclusion as to whether it should interfere at all in actions between medical men. As to the wisdom of such interference, the members have already expressed an emphatic opinion in a resolution passed at the crowded annual meeting of 1893. Indeed, in the absence of fuller information, which the Council has declined to afford either to members or to the Supreme Court, it is difficult to conceive how an elected Council could have ventured to act in opposition to the spirit of so definite an instruction. To a certain extent some of the complications of this unfortunate affair have arisen from the existence of a dual secretaryship. The resignation of Dr. Leslie Phillips, an old and tried official, has paved the way to a simpler administration of the secretaryship, but we are of opinion that no change will be really efficient unless it substitutes a paid and responsible officer for the present cumbersome arrangement. Upon this and other matters, however, we understand that the Society will shortly be invited to express an opinion. The days of the Union are young, and it cannot afford to be even suspected of unduly interfering in private business actions between medical men. Only a short year ago the Association found itself plunged into debt through the costs of a similar internecine conflict. The member on whose behalf that debt was contracted occupied, as our readers will remember, the position of President of the Society. It is doubly unfortunate, then, that the costs now incurred in the Bloxham case should be on behalf of a member of the Council. The Medical Defence Union is a society to which many earnest men have looked hopefully as one pregnant with future possibilities of good to the profession. It has been regarded not only in the narrow sense of a protective corporation, but also as the germ of a great movement towards the consolidation of other and wider interests. The present appears to be the critical moment which comes sooner or later in the history of all such societies. It would be a thousand pities if the mistakes of a session were allowed to wreck the results of many years of patient and painstaking effort. At the same time it cannot be too firmly insisted upon by members of the Union that the Council is an elected administrative body, and is therefore the responsible servant of the Society. It is rumoured, with what degree of truth we cannot determine, that of late a spirit of parochial narrowness and jealousy has influenced the actions of the Council. We should be slow to believe that such a state of affairs has arisen, but, in any case, the rumour is one for the Society to deal with and discuss. Whether or not the Medical Defence Union is to fulfil the promise of its vigorous youth will depend on the firmness and energy of its members in asserting their rights against any assumptions of arrogance or of bureaucracy on the part of its governing body.

◆

Notes on Current Topics.

The late Professor Brown-Sequard.

Medical science has suffered a great loss by the death last week of Prof. Brown-Séquard from pulmonary congestion. We are indebted to our French Correspondent for the following sketch of his career: Born at Port St. Louis in 1817, Brown-Séquard came to Paris in 1838 to complete his medical studies, and took his degree two years later. He immediately devoted himself to the researches of experimental physiology, on the composition of the blood, animal heat, affections of the spinal cord, and the nervous supply of the sympathetic ganglia. In 1864 he went to the United States, and was appointed Professor of Physiology and Nervous Diseases at the Harvard College. He returned to France in 1869, where he remained but four years, when he went back to New York and founded the "Archives of Scientific and Practical Medicine." On the death of Claude Berna[illegible] he returned to France, and was elected to the [illegible] chair of that illustrious physiologist. In 1886 Brown-Séquard became a member of the Académie des Sciences, and was created a Chevalier of the Legion of Honour. Such was the *curriculum vitæ* of the eminent *savant*, but it must not be inferred that all was *couleur de rose* in his life. Brown-Séquard may be truly called a self-made man. While yet a student, he was burning with zeal for the field in which he was destined to make such a brilliant name, devoting all his meagre pecuniary resources to the purchase of instruments and materials necessary in his search after knowledge. Frequently he had exhausted his straitened allowance, and numerous are the stories related by him with much humour about the plans he resorted to to acquire the "subjects." One day he succeeded, by considerable privation, in procuring a dog and a coat, this latter to pay a visit to a doctor who was to take him as an assistant, the dog was for experimental purposes. Being obliged to absent himself for some hours, he shut the dog up in his room. When he returned the dog had eaten the coat! Brown-Séquard had gained an immense popularity in late years by his method of regenerating the debilitated nervous system with injections of organic solutions, fully described in this journal. When he announced to the Académie des Sciences his method, and, above all, when he coolly stated that he had tried it on himself, and felt in consequence that he was ten years younger, his colleagues smiled ironically. The press especially tried to hold him up to derision, but the venerable physiologist stood the storm, and he had the satisfaction of seeing his novel treatment followed by very many of his medical brethren in all parts of the world. Brown-Séquard had attained to the age of 77, and was married three times. The death of his last wife preyed much on his mind, and contributed in some measure to his unexpected end.

The Dublin Students' Emeute.

The Council of the College of Surgeons, in due time and without hurry, deliberated last Thursday upon the demands of the students to which we have already referred, and delivered a conciliatory reply. As regards the question of remitting the rejected student to further studies, they intimate that it will be time enough for the students to complain when any considerable number of them are sent back to such work. As to the diploma fees, which are declared by the students to be excessive, the College has intimated its intention to confer with the College of Physicians on the subject, and has expressed, in a general way, its agreement with the complaint of the students. It also meets the student half way on the question of the re-examination fee, and assents to the proposition that an idle or ignorant student shall pay for re-examination only what he costs to re-examine. At the same time the Council of the College points out that, in the London Colleges and elsewhere the re-examination fee is three or four times as large as that of the Irish Colleges. The students held further meetings, and probably the newspapers will contain further terrifying manifestoes from them! We again venture to counsel calmness and discretion, and to deprecate hurry and heat. It is not to be supposed that Colleges are going to settle questions which involve important principles and the loss or gain of thousands of pounds in a few hours at the dictation of students. The College of Surgeons could not do so if it wished. The students have advanced their cause by bringing to the front questions which deserve to be quietly discussed, and grievances which are recognisable, and we hope they will not spoil their chances of success by talking nonense and asking that things shall be done in a moment which, if ever done, will necessarily take time.

Dr. Briggs and the War Office once more!

It is hardly credible that the Army administration should venture to continue their persecution of Surgeon-Lieutenant-Colonel Briggs in face of the resolutions in Parliament and of Mr. Stanhope's declaration that he had only done what any man was bound in honour to do. The facts of the case, however, as stated by this much-persecuted officer in a printed circular addressed to Members of Parliament, show that the military authorities have no intention of allowing Mr. Briggs to hold his commission in peace. The absolute necessity of army administrative reforms of a sweeping nature are loudly insisted upon by a certain class of journalists and politicians. The treatment of Mr. Briggs assuredly points the moral of their clamour, for that officer has been three times reinstated in the service and four times deprived of his commission. The action of the Commander-in-Chief appears to have been of the autocratic nature that one is given to understand rules the service of the Czar. He has refused again and again to have the matter referred to a public trial, and yet has not the common honesty to forget his grudges when Surgeon-Colonel Briggs is reinstated in his post. An occurrence of this kind is not calculated to increase the confidence of the public in the administration of the Army, and is bound to alienate the sympathies of medical men.

Salicylic Acid as an Ecbolic.

Salicylic acid and its salts have become of such general use that it cannot be considered out of place to draw attention to the fact that in about one-third of the cases in which it is given to pregnant women it produces abortion. The subject for the past five or six years has been attracting attention. Dr. Shaw has reported two cases in which the use of the salicylate of soda produced bleeding, and in commenting on them writes: "The treatment of acute rheumatism by salicine and its derivatives is so widely popular that it is of great importance to consider any drawbacks there may be in its adoption." Somewhat similar views were advanced in the Clinical Society's discussion on the subject. Rinz, however, from his experience with the acid, and from a study of the literature of the subject, concludes that salicylic acid acts on pregnant wombs as an ecbolic. The question will naturally arise as to the purity of the sample used, but we think when salicine has been found to produce bleeding from the gums and nostrils, we may fairly conclude that bleedings following on the use of salicylic acid or its salts are not the results of impurities in the specimen, but are due to the physiological properties of the drug.

"Immodesty in Hospitals."

Under the above prurient title the letter of a correspondent, who signs himself "An Indignant Husband," has recently appeared in a London evening paper. The communication in question is so characteristic of a certain kind of moral pathology that we reproduce it in full:—

> "Sir,—My wife, suffering from a disease peculiar to women, and wishing to avoid the expense of a long doctor's bill, attended the out-patient department of one of our great hospitals. She went prepared to submit herself to a thorough examination. Judge her surprise when she found herself surrounded by a crowd of gaping and jeering students, chiefly boys barely out of their teens. She returned home in a state of extreme nervous excitement, detailing to my private ear the nature of this degrading and disgusting exposure. Although only a working man, I immediately called in a private doctor, under whose care, and without any painful and indecent exposure, my wife is now regaining her health. Surely there must be something wrong in the management of our hospitals when our wives and daughters cannot attend them without submitting themselves to these and similar outrages.—Yours, &c.,
>
> "An Indignant Husband."

With regard to this extraordinary epistle it may be noted: First, if the husband was able to pay a doctor, why did he allow his wife to receive charity? Secondly, we challenge the writer to prove the presence of a crowd of "gaping and jeering" students on such an occasion in an hospital in London, or any other part of the United Kingdom; and, more than that, we have no hesitation in saying that his assertion is untrue in word and in fact. Thirdly, any medical man who treats uterine maladies without examination is likely to do an injustice to his patient. Fourthly, the investigation which is a necessary preliminary to thorough treatment can be neither indecent nor immodest when regarded from a pure and proper point of view. The only impurity involved is that suggested by the patient, who attributes motives of the basest kind to a necessary routine clinical proceeding. Lastly, the presence of students is, rightly enough, one of the conditions under which medical charity is granted.

Sewage Electrolysis.

Dr. Kelly, Medical Officer of Health for the Borough of Worthing, and of the combined sanitary district of West Sussex, has published his report upon M. Hermite's system of treating sewage matter with electrolysed sea-water. We briefly referred to this subject last week. His trial has been of an elaborate nature, and contains analyses, chemical and bacteriological, by Drs. Dupré and Klein. Dr. Kelly's is the first public investigation in England of M. Hermite's system, and it is somewhat disappointing to find that his report is an unfavourable one. With regard to the question of cost, Dr. Kelly points out that in addition to the annual expenditure in providing sufficient electrolysed water there would be a very great outlay in putting down the requisite plant in the shape of fresh mains, pipes and cisterns, so as to furnish a supply to every household.

Frauds on Medical Men.

The specialism of crime has long since produced the thief who devotes his skill and energies to the plunder of medical men, Coats, carriage clocks, instruments, umbrellas, books, and other portable articles lying about consulting and waiting rooms form the chief objects of attraction. From the nature of his pursuits it is as a rule particularly easy for any rogue to gain access to the interior of a doctor's household. Quite recently an old specialist of this class was sentenced at the Old Bailey for a series of offences. In the first case, although watched by the page-boy, he carried off a hat and other articles from the house of Dr. Smith, of Great Portland Street. He then visited Dr. Elam's, of Upper Montague Street, and stole a clock worth thirteen guineas from the consulting room. His next feat was to steal another carriage clock from the house of a lady doctor in Gower Street. His last fraud was of a more elaborate character, and involved the use of a forged telegram and a forged cheque, by means of which he induced Dr. Selwyn Quartley to lend him a sovereign. One is glad to find that the Recorder has put this enterprising specialist into safe keeping for the next five years. Medical men will do well to remember that London, and indeed every other large city, abounds with rogues of a similar stamp, and servants in a doctor's household should be specially warned to keep an eye on the movements of strangers.

The Royal College of Physicians of London and the Gresham University Commission.

At the Comitia of the Royal College of Physicians held on the 5th inst., the consideration of the report of the delegates on the Report of the Royal Commission on the Gresham University Charter was dealt with, and after a long discussion the following resolution was agreed to:—"That the delegates of the two Royal Colleges do cordially approve of the general provisions in the Report of the Gresham University Commission, particularly in so far as they relate to the said Colleges, regarding them as being in accordance with the principles which the Colleges have hitherto affirmed and accepted, and as constituting the most comprehensive and academic scheme hitherto proposed." Two amendments were proposed prior to the above resolution being put, but they were both lost. Although, perhaps, the scheme could be improved in certain particulars, we are nevertheless strongly of the opinion that a University founded on the lines laid down in the Report of the Commissioners should be included as quickly as possible among the London medical corporations. The longer the delay the greater will be the loss to the London medical schools. The outlook, even now, in this respect, is by no means encouraging. Indeed, before very long, if the same attractions for medical education in the provinces be maintained, the result will be that London will be a teaching centre for medicine—only in name.

Le Caron as a Medical Man.

The death of Le Caron, the notorious Fenian spy, ends the last chapter of an extraordinary career. During the last twelve months he has suffered from a painful internal complaint, which proved fatal a few days since at his residence in South Kensington. For two years he had lived a retired life in the neighbourhood mentioned, where he passed under a name that had been assumed, no less than that of Le Caron, and adopted from an aristocratic English family. Strange to say, he posed among his neighbours, and even to his landlord, as a retired medical man. So far as we know, his only claim to any such distinction lay in the fact that he once carried on a druggist's business in America, and that he retired from the American army with some honorary compound title which contained the word "surgeon." It is certain, however, that he had not studied medicine, and was not a qualified man. The medical profession will hardly appreciate the honour that has been forced upon them of affording vicarious shelter to a man whom Sir Charles Russell denounced as "a living lie, who had subsisted by the betrayal of his friends." It is not a little remarkable that Le Caron closed his dangerous career by dying peacefully in his own home.

Progress of Female Medical Education.

As evidence of the rapid strides being made by women towards the medical goal, reference need only be made to the examinations just concluded in the University of Glasgow. Thereat passed fifteen for the first professional M.B. and C.M., seven for the second, and two for the third examination. This, be it remembered, is what is taking place at one institution only. The increase, it is true, is not so marked in England, but Edinburgh and Dublin show unmistakable evidences of its onward progress, in order to prove, we may assume, that enlightenment blossomed only in the latter part of the nineteenth century, and to "show us how divine a thing a woman may be made." Hitherto man has been accused of making "medicine divine," but the *fiat* of his doom has gone forth—he has had his day, and the divinity which was wont "to shape *our* ends" is now wooed and won by woman.

Nursing in Excelsis!

When, some twenty years ago, the passing generation of our profession were, for the first time, horrified by the proposal that the nursing Gamps of that day should be superseded by lady nurses specially trained for the purpose, they could have had little idea of the popularity and importance to which the nursing sisters of to-day have attained. Not only have these ladies completely routed all other sorts and conditions of nurses out of the field, but they have succeeded in making themselves somewhat of a fashionable craze. They have their own special Bill in Parliament for the purpose of elevating them to the position of a recognised branch of the medical profession. More remarkable still, they have a pension fund amounting to nearly £170,000, with an annual income available for pensions, &c., amounting to over £30,000. Four individuals in the City of London contributed of themselves £20,000. The contrast of this capital sum of £170,000 and this yearly income of £30,000 enjoyed by the nurses with the paltry yearly income of £3,728 enjoyed by the Society for the Relief of the Widows and Orphans of Medical Men is illustrative of the substantial advantages gained by those who can make themselves the fashion, and of the sparing sympathy which the public expends upon poor people who have few friends and cannot help themselves.

The Chelsea Vestry and the Hospital for Women.

The Chelsea Vestry, at its last meeting, appointed a Committee to consider and advise the Board what further action, if any, should be taken in the matter of the Chelsea Hospital for Women. At the ordinary meeting held on the 3rd inst. this Committee reported that they had carefully considered the reports of the Medical Officer of Health on the subject, and the communication from the treasurer of the hospital, with the comments of the Medical Officer of Health thereon, and also the letter from the President of the hospital, asking whether the Vestry would nominate one of their number to serve on a committee of inquiry. The Committee recommended that the Vestry decline to be represented on the proposed committee, and they were of opinion that the professional members of the committee should be limited to members appointed by the Royal Colleges of Physicians and Surgeons of London. Strong objection was taken to the appointment of the consulting medical officers to the board of inquiry, and we must confess that we think this contention on the part of the Vestry is quite correct. The officials at the hospital should act absolutely without partiality in the matter, and display no suspicion of favouring their own side. By adopting this policy they will gain adherents to their cause whose support might be of some value to them in the future.

A Curious Position for a Coroner.

The newly-appointed Deputy Coroner for East London, Dr. E. K. Houchin, found himself in a curious dilemma at an inquest a few days ago. The inquiry was held for the purpose of ascertaining the circumstances of the death of an infant, æt. 3 months. The mother deposed that the child was suddenly taken ill on the 1st inst., and died the same evening. She sent for a doctor, but he was unable to save the child. At this stage of the proceedings the Coroner informed the jury that the doctor who was called by the mother was himself. Here, then, appeared to be a difficulty out of which it would not be easy to escape. But the Coroner was equal to the occasion: he stated that as it was impossible for him to give evidence, and at the same time act as coroner, he had related the facts of the case to another doctor, who would therefore give evidence in his place. This arrangement was duly carried out, and the jury immediately afterwards returned a verdict of death from convulsions. Such an experience as that above narrated must surely be a unique one in the records of "coroners' courts."

The Medical Battery Company.

The Medical Battery Company is again the subject of public notice. The creditors of the Company were called together last week to consider a scheme of reconstruction devised by a joint committee of debenture holders, shareholders, and those having claims against the manufacturers of the so-called electropathic belt. The meeting was a private one, the purpose of the gathering being stated to be merely to gain, informally, some opinion on the methods advocated before these were submitted for formal adoption. In time, perhaps, some entirely new electropathic appliance will be made to bid for popular favour in the place of the discarded belt.

The Carlow County Infirmary.

The position of Surgeon to this Infirmary, vacated by Mr. O'Callaghan, was filled on Tuesday, the 3rd inst., by the appointment of Mr. Broomfield, of the City of Dublin Hospital, to whose candidature we have already referred. Mr. Broomfield is well and favourably known as a surgical teacher in Dublin, and has been acting for Mr. Croly in the surgeoncy of the City of Dublin Hospital for some months past. He is also a Councillor of the Royal College of Surgeons, Ireland, and has been named as a representative of the College at the approaching Congress of Hygiene and Demography at Buda-Pesth. Mr. O'Callaghan, as we have said, leaves Carlow Infirmary, and will take up his practice in Harley Street, London. His speciality is abdominal surgery, and we believe he has learned the speciality with Mr. Lawson Tait. He was successful in raising the Carlow Infirmary to a position of popularity and efficiency which it did not always occupy.

Maternal Impressions.

The perennial subject of maternal impressions is one of great interest to the medical profession, and although we find nothing in either medical or general literature to give countenance to some of the cases put forward, especially by the uneducated classes, nevertheless many strange cases placed on record by respectable and accomplished physicians cannot be explained otherwise. The most recent and one of the most marked evidences of this influence is the case recorded by Dr. Garthright (*Virginia Medical Monthly*), which is as follows:—Mr. ——, by the explosion of a keg of powder, was severely burned about the hands, arms, face, and neck. When taken home, his wife, who had been pregnant for five months, met him calmly, and, she says, without the slightest trepidation. In September following the wife was delivered of a female child. On examination of the child the eyelashes and brows were seen to be absent, the eyelids thickened, and the conjunctiva inflamed; its left ear, like that of its father, was doubled upon itself; on its chin was a large cicatrix, and its whole face was covered with dark brown blisters; on its neck was a large abraded surface; its hands and arms were similarly blistered; its left thumb was bent over the index finger, and the other fingers over the thumb – in a word, the newly-born baby closely resembled, in its disfigurement, the father after he had been injured by the explosion. We offer no explanation of the subject, we simply report a case. So far, discussion on maternal impressions has not been productive of much good, but from time to time the subject forces itself on the notice of the medical profession, and we are brought face to face with facts that in the near future require interpretation.

The Secretaryship of the Royal College of Surgeons, Ireland.

On Thursday last Dr. Robert H. Woods was elected to be Secretary of the Council in the room of Dr. A. H. Jacob, resigned. There were six candidates, Mr. J. Barton, Mr. Goulding, Mr. Hilles, Mr. Pratt, and Mr. Glasgow Patteson, all Fellows of the College: Mr. Woods is surgeon to the throat department of the Richmond Hospital, and presents a very distinguished University record, having gained a gold medal in experimental physics. The salary has been reduced from £250, which Dr. Jacob received, to £100. Mr. Woods is young, quick, well-educated, and ready for work, and ought to make a good secretary. He will have plenty to do.

The Degrees of Fertility at Different Age-Periods in Men and Women.

Some interesting observations were communicated at the meeting of the Royal Society on January 18th in a paper by Joseph Koösi, member of the Hungarian Academy of Sciences. The subject was an inquiry into the fertility of each sex, based upon observations made with regard to statistics available at Buda-Pesth. Among husbands of 39 years of age, the probability of becoming fathers is, with a wife of 20 years, 31 per cent., and with a wife of 30 years, 20 per cent. On the other hand, for husbands of 40 years, the chances are with a wife of 35 years, 27 per cent.; with one of 40 years, 17 per cent.; and with one of 45, only 2½ per cent. Again, two degrees of fertility appear to exist for each age, namely, the physiological and the actual fertility. The former is the result of the unrestrained exercise of the sexual functions, while the latter is the outcome of such functions controlled by forethought, initiated by motives of morality. It is among newly-married couples, admits the author, that the physiological factor is nearly exclusively active. But after the birth of the first child, the degree of physiological fertility declines, and under the influence of the moral factor, it is reduced to an extent exceeding all expectation. For example, with mothers of 30—35, the reduction is to 78 per cent.; with those of 43, to 2 per cent.; that is to say, 98 per cent. of the physiological faculty is suppressed in these latter cases. With men the influence is also very great, though it is less pronounced than in women.

The Coronership for North Dublin.

The election of a Coroner for the North City in room of Dr. Davys, deceased, takes place this day (Wednesday). It is remarkable how little interest has been excited in the giving away of this valuable appointment, and the indifference shown is the more remarkable because the selection lies with the whole of the Parliamentary electors of the North Dublin district, and it is a rare phenomenon to see placidity when so large an Irish constituency has to be polled. Indeed, we should have with enthusiasm joined in the fray ourselves on behalf of the medical candidate if we had known last week of his candidature. There are two competitors, Dr. Murphy, of Skerries, an intelligent and experienced member of our profession, and Mr. Friery, a solicitor. Of course we are aware that, in all such elections the only qualities worth naming are politics, religion, and family connections, and we believe that Dr. Murphy fills all the requirements in these respects, but, in addition, is a capable man, which is more than can be said for some Irish coroners. He, at all events, will know something about a cause of death, which, probably, is more than his lawyer competitor can boast of. We wish him success.

◆

The Eleventh International Medical Congress at Rome.

[From our Special Correspondent.]

Rome, April 5th.

This is the last day of the Congress, and by the time these lines are perused by your readers this great and successful meeting of medical men will have become a matter of history. In the midst of so many and great attractions, and within easy reach of the far-famed bay, a visit to which is generally held to be necessary before a person becomes qualified to die, it is not surprising that the purely scientific objects of the *réunion* should in a measure have been overlooked by the members. Indeed, no secret has been made of the fact that a large proportion of the medical men attending the Congress with their wives came solely for the purpose of making use of the excellent facilities provided for them for seeing Rome and its vicinity under the most favourable circumstances. What wonder, then, that attendance in the Sections should have frequently been of limited degree! What more natural than that the members should have exchanged the attraction of listening to the periods of a *savant* on some abstruse professional topic for that of a well planned excursion to some place of interest either in Rome or its neighbourhood. If, however, science has been at a discount, so far as the bulk of the members are concerned, nevertheless, the enjoyment derived from the visit has, I should imagine, made ample amends in causing them to congratulate themselves upon having undertaken the expedition.

Some Interesting Statistics.

The general secretary, whose duties will by no means have come to an end when the Congress terminates, has published some interesting details regarding the attendance of the members, &c. He asserts that the attendance from Germany was upwards of 900; England and her colonies about 700; the Austrian Empire and the Hungarian Kingdom, 700; France about the same; Spain, Russia, Switzerland, and the United States of America about 200 respectively; and 500 members came from Portugal, Sweden, Norway, Holland, Belgium, Turkey, Roumania, Servia, Greece, Mexico, the different South American Republics, and Japan; while there were lastly even representatives from Borneo and Figi. Thirty-two

Governments and 425 scientific bodies sent their representatives, and "more than 1,000 ladies," he gallantly concludes, "connected with medical men have met here from every country to mitigate with the charm of their presence the severity of our work." We have it also on the authority of this official that no less than 2,700 papers had been received for reading and discussion in the sections—an amount of material almost four times in excess of that which was available for the Congress held in Florence.

Professor Baccelli, the President.

The medical profession in Italy must, or at all events should, feel proud of their *confrère* Professor Baccelli, the President of the Congress. He has attained to a position in his country which is probably unique so far as medical men throughout the world are concerned, that is to say, he occupies a seat in the Italian Cabinet as the Minister of Public Instruction. In reflecting upon this fact, it is impossible to avoid drawing comparisons between England and Italy in this regard. When will a member of our profession be offered a seat in the English Cabinet? That is a question to which most of us probably would like to have an authoritative reply. Meanwhile we are again reminded by this circumstance that the English medical profession takes a more insignificant position in connection with affairs of the State than is the case in any other European nation.

Sir Joseph Lister.

The following letter was received by the President from Sir Joseph Lister:—

12 Park Crescent, Portland Place, London.

Most Illustrious Professor,—After the great honour which your classic city has done me, on the proposal of Prof. Durante, by placing my effigy in your new Surgical Clinic, it would naturally be not only a duty, but a great pleasure for me, to be present at the Congress over which you will preside, and to return personally my best thanks and the homage which are your just due. The terrible shock, however, which I have undergone through the loss of my beloved wife has deprived me of the heart for such an enterprise.

Therefore, dear Prof. Baccelli, please accept my excuses and at the same time my best congratulations for the honour done to us by your Sovereign, who has entrusted you with the Ministry of Public Instruction.

My heart will be with you in the Congress, which has my heart-felt wishes for a brilliant success.

Your friend and admirer,

Joseph Lister.

What o'Clock is it?

Those members who have not been to Rome before have had to get themselves accustomed to a little horological detail the ignorance of which is calculated at times to cause some embarrassment. The Italians take the hours of the day just as they come, and in rotation endorse the numbers on their timepieces. The twenty-four hour clocks are the fashion; consequently an announcement that an entertainment will take place at 21 o'clock reads somewhat startling at first. Perhaps, however, this method of numbering has its advantages. Certainly it must have the effect of reminding people that if they receive an invitation for a 21 o'clock performance there is not much of the day left for the purpose.

The "Dies Non" of the Congress.

Sunday, April 1st, was, of course, an official "dies non" so far as the work of the Congress was concerned. The Mayor of Rome invited the delegates and representatives to a grand instrumental concert at the "Constanzi Theatre" at half-past one. The programme was performed by the Municipal Band, and included selections from the works of Meyerbeer, Schumann, Mendelssohn, Wagner, Saint-Saens, Mascagni, Verdi, Rossini, and others. An excursion afterwards took place to the Roman Castelli, in which the ladies of the Congress were *not* privileged to take part. By way of further amusement, a "bicycle race meeting" was carried out under the auspices of the Roman Velocipede Club.

A French Banquet.

The French members of the Congress gave on the 3rd inst. in the Sala Dante, Via Della Stamperia, a luncheon in honour of Professor Bouchard, President of the French Delegates. The French Ambassador for Italy was in the chair, and among the guests was the President of the Congress. Great enthusiasm was displayed throughout the proceedings, which in every respect passed off without a hitch.

An Anglo-American Reception.

Mention should be made of the Anglo-American entertainment, comprising a reception followed by a Cinderella, organised by Mr. S. M. Burroughs, in honour of the English and American members of the Congress. The *réunion* took place on Saturday, the 31st ult., at the Grand Hotel, and was a conspicuous success.

The Members of the "Fourth Estate" at the Congress.

The Scientific Press came in for a large mead of recognition at the Congress. In the first place a meeting was held in the Hall of the Surgical Section for the purpose of discussing the question of establishing a section for the Medical Press in future Congresses. But for the first time in the history of these meetings a special function was held in honour of the members of the Medical Press who were present. A lunch was given by the Scientific Press Committee to their foreign and Italian colleagues, and a large number accepted the invitation and took part in the proceedings. Dr. Casati, as the *Doyen* of the Italian Medical Press, welcomed the visitors; and the toast was also supported by Prof. Rubino, who spoke in French. Prof. Laborde replied on behalf of his French colleagues, and the other official representatives who were present responded for their respective countries. Prof. Lucatello summed up, as it were, "the whole situation" by making a speech in each of the four official languages of the Congress, in the course of which he said that if in the literary republic the sentiment of good fellowship bound journalists together, with medical journalists friendship must give rise to the most cordial and sincere brotherhood, because the Scientific Republic is the most democratic republic. The proceedings, which were most cordial throughout, were fittingly brought to a close by a charming young lady producing her camera and taking a photograph of the group of the medical members of the "Fourth Estate."

The Closing Scene.

The final proceedings were of a very cordial and enthusiastic character. The President, in bidding the delegates farewell, said that in attending the Congress they bore testimony to the fact that for enlightened minds the claims of Science were paramount. He proposed that the next Congress, which would be the 12th, should be held in Russia, leaving it to the Government of that country to determine the place of meeting. In conclusion, Professor Baccelli, who was frequently interrupted by cheers, expressed his warm thanks to all the delegates for their labours. M. Danileffsky, in the name of the Russian Government, accepted Signor Baccelli's proposal, the announcement being received with applause. The representatives of all the foreign Committees then spoke in turn, and referred in terms of warm recognition to the hospitality shown to them by the King and Queen of Italy and the Italian Government. Signor Baccelli, in thanking the delegates on behalf of the Government, expressed the hope that universal scientific concord might always bear the richest fruit.

The Final Lunch.

The final official act of hospitality took place to-day at 12 o'clock, when a lunch was given to the members of the Congress and the ladies. The function was held in the "Terme di Caracalla." Three or four days ago, however, an odd incident occurred in connection with this arrangement. An official announcement was made that several packets of invitation tickets for the lunch had been stolen, consequently it was found necessary to cancel all those which had already been issued to the members, and to prepare a new set. It is to be trusted that the adoption of this plan effectually frustrated the designs of the enterprising thief.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

A University Degree for Scottish Licentiates.—The University Court of St. Andrew's University have resolved by a majority of seven to three to petition Parliament and Her Majesty in Council, or to do whatever may be necessary to have substituted for some sections in the St. Andrews Ordnance No. 4 the following section or provision :—"It shall be competent for the University of St. Andrew's to confer medical degrees after a certified medical curriculum of five years at recognised medical schools, and after careful examination, conducted under the Inspectors of the General Medical Council of Medical Education and Registration of the United Kingdom, on candidates who have not studied medicine at St. Andrew's or any other of the Scottish Universities, provided that the degrees under this section shall be given only to Licentiates of the Royal College of Physicians of Edinburgh, of the Royal College of Surgeons of Edinburgh, and of the Faculty of Physicians and Surgeons of Glasgow." This is, we suppose, the first definite move which has been taken with regard to this subject, which we alluded to some months ago, as a means of counter-balancing the benefits of a University degree proposed to be offered to the London Colleges when the London University has been set up.

Glasgow University Council—Admission of Women to Bursaries.—The statutory half-yearly meeting was held on the 4th inst. Professor Heckless, in pointing out that he was unable to agree with the majority of the Business Committee in approving, even generally, of the draft ordinance relating to the admission of women to bursaries, scholarships, and fellowships, said it was beyond question that, having been admitted to the University, they ought to be so entitled in respect of all such foundations and on exactly the same conditions as other students or graduates. The position of the draft ordinance seemed to be open to some strong objections, and one was, that because the appropriation of certain bursaries to competition among women only involved in their case an easier competition from the fewness of the competitors, and a consequent loss of the academic distinction which in public esteem was connected with the gaining of a bursary. He thought the Council would agree with him that if women were fit to compete for bursaries and scholarships with men in regard to a certain number, there was no reason why they should not compete in regard to the whole of them. Professor Ramsay moved another amendment to the effect that it be left to the discretion of the University Court to admit women to bursaries under certain conditions and limitations which they may think proper. The two amendments were put to the meeting, when, by the casting vote of the Chairman, Professor Heckless' amendment was carried, which was then put against the report of the Committee, and was carried by 19 votes to 6.

The Irish Veterinary College.—The Glasgow Town Council agreed to communicate the magistrates' minutes submitted last week in reference to the proposed Government grant for the establishment of a Veterinary College in Ireland to the Government. The opinion expressed in them is to the effect that if such a grant were given the existing veterinary colleges in Scotland should also receive grants, so as to enable them to compete on equal terms with the Irish College. This opinion is being widely given expression to by various public bodies in Scotland.

In the annual golf match between the Royal College of Physicians and Surgeons of Edinburgh the Surgeons again wrested the trophy from the Physicians, who won it for the first time last year. The match was, as usual, played at Gullane between fifteen on each side.

Special Articles.

EMBALMED AND CREMATED.

The depressing and meaningless nature of the funeral ceremony as usually conducted in this country has been fully discussed and condemned in and out of the press, and it may now be fairly left to the Funeral Reform Association to effect some change for the better in its character. The people of the Eastern portion of the Empire, however, take a very different and in many respects a more cheerful and enlightened view of the disposal of their dead. A good deal might be said in favour of the method formerly adopted by the wild Hindu who launched forth the corpse on its frail raft to descend the sacred river, and watched with prayers and songs until it was lost to view. A good deal more might be said in favour of the method which still prevails throughout our Burman empire. Here, among the better classes, the disposal of the body is truly ceremonial accompanied by music and rejoicing of a most remarkable nature. It receives an elaborate preparation for the event. It is embalmed and lies in state for several weeks, during the whole of which time a continual musical festival takes place, and ultimately the body is cremated amid a great display of fireworks. Mr. Justice Jardine in his book on the Burmese Empire, furnishes us with an excellent account of these elaborate ceremonies which took place on the death of a Ponghi, or priest, whose body would probably be more highly honoured, than that of an ordinary person. In this case we learn that soon after death the body was eviscerated and the embalming conducted with scrupulous care in every particular. The body was now filled with spices herbs and resins; the limbs brought into close juxtaposition, and then swathed by bands of white linen, passed many times round, and upon which a thick coating of spirit varnish is laid. In a short time this is ready to receive a complete covering of gold leaf. It is now placed into an elaborately ornamented polished chest or coffin, which some time previously had been made ready to receive it. On this large chest much care and expense is bestowed to make it a fitting receptacle for the body of one held in much veneration. Indeed, the great Talapoins have them made several years before death, and usually excite much curiosity. This chest is also gilt throughout and adorned with sculptured flowers, and sometimes precious stones. In its superb receptacle the body is exposed to public view for many days or weeks, during which time the musical celebration goes on, and those who come to view it offer gifts of rice, flowers, and money, which are usually sufficient to defray the funeral expenses. At length the day arrives for the final part of the ceremonies, that of the cremation of the body. The chest is now placed upon a large four-wheeled car, to which are affixed a number of ropes, so that the people may drag it to the ready combustible pile. Men and women eagerly engage in this work, all contend for the honour of taking a part in the holy work. On arriving at its destination it is received by a regular *feu de joie* of rockets and other kinds of fireworks. The pile also conceals a number of inflammable materials, and after the body is placed in position these are lighted and the work of destruction soon completed. Similar funeral ceremonies are very general among all classes, who in this demonstrative way show their respect for their departed friends, and who firmly believe that they best commend his spirit to the omniscient *Nat*, the creator of the world.

WHAT CONSTITUTES UNSOUNDNESS OF MIND?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Drs. Goodall and Craig ask me to define my meaning of the term "Climacteric Mania," as used in my letter in your issue of March 28th, and add that it is pretty clear I do not mean "Insanity." They are quite right, I most emphatically do not mean "Insanity." My contention is that women passing through the climacteric are in the first instance never "Insane." That in some instances if great care and attention is not bestowed upon them insanity supervenes there is no doubt; and if it is desired to accomplish this end, I can conceive no more certain way of doing so than by placing these cases into an asylum, where their associates are confirmed lunatics and the surroundings depressing. Drs. Goodall and Craig say "that all who have experience of asylums will agree that this 'Contact Insanity' is in the highest degree uncommon, that practically it is a myth." I shall be forgiven, I trust, if I venture to question this statement, and I contend it is only by most careful and searching inquiry that such a question can be answered in a trustworthy manner.

The term "Mania" as applied to this disease is certainly misleading; a more correct meaning would be conveyed by the expression Mental Disorder connected with the Climacteric. The whole nervous system is in disorder, and most susceptible to develope unhealthy tendencies. It is then, I contend, absolutely necessary that those suffering in this way should have the utmost care and attention.

How? Certainly not by placing them into an asylum, for here, in my opinion, the mental and moral influences are exactly what should be avoided.

Take those showing a tendency to melancholia or hypochondriasis. Is it to be supposed that these are likely to derive a benefit by being placed, more or less, under lock and key, and to be associated with others suffering from different forms of insanity? Does not common sense dictate that such cannot be the most appropriate form of treatment. What then is required is that women suffering in this way should be removed from their home associations, and be placed elsewhere, where they could have bright surroundings, cheerful companions, change of air and scene, and be as much as possible supplied with bodily and mental amusements.

It is here, as I have pointed out, that the difficulty arises, for among those who are unable to pay for such a change, at present there is no home provided into which such patients can be removed, and thus the chances of their recovery are much lessened. If such homes did exist, I am strongly of opinion that a large percentage of cases would be safely guided through this critical period, and that it would be found that many more than 30—40 per cent. would recover.

The question is to my mind so large and important that I cannot help thinking much good would accrue if a committee were formed composed of equal numbers of general physicians, psychologists, and gynæcologists, to inquire into and report upon the subject.

I am, Sir, yours, &c.,

Fredk. Bowreman Jessett, F.R.C.S.

1 Buckingham Palace Mansions.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Whatever may be thought of Dr. H. Macnaughton Jones's views as to what "constitutes unsoundness of mind," he does not appear to me to suggest a very lucid exposition on the principles and spirit of law which might be supposed to govern the class of cases in question. I note he remarks: "I for one certainly feel that the interests of the public and profession, as well as the safety and liberty of numbers of afflicted women, have been best protected by the verdict of the jury in the case of the Commissioners in Lunacy *versus* Sherrard;" and he appears to offer this as a natural deduction from his previous experience, because he says, "I have had several cases of women with melancholia and delusions who have received in the houses of medical men careful supervision without certificates." Now, Sir, although I do not presume to offer any direct criticism on, nor express any opinion upon the justice of the verdict above referred to, I certainly claim to be allowed to state that this verdict is a very unhappy illustration of "the safety and liberty of numbers of afflicted women," that is to say, if it is intended to establish a precedent and encouragement for the ordinary run of medical men to go and do likewise, and so far from its operation being in the interests of the public and profession, it would appear to me to be *as a precedent* dangerous to the former and embarrassing to the latter. In order to illustrate my meaning I will suppose Dr. Jones's doctrines were to become the common practice of the day, for medical men in pursuit of patients of this class to frame advertisements conveying to the public the idea that those only were required "within the borderland of insanity." Now it is quite clear that a certain percentage of these would overstep the "borderland," and that accidents might more or less frequently occur, certainly more frequently than if these patients were placed under legally authorised restraint. It is obvious that the Commissioners, on the face of the verdict in question, would be chary in instituting legal proceedings; but let us suppose, further, that in spite of this verdict they frequently do so, the practitioners being responsible for the accidents which may from time to time occur, would naturally plead that the "borderland of insanity" had been suddenly overstepped, and it would certainly be most difficult to disprove their assertion, and they would almost certainly gain a verdict, even were it only on the practice of English law, in giving the accused the benefit of the doubt. On these grounds I fail to see how such a condition of things could conduce "to the safety and liberty of numbers of afflicted women" and the "interests of the medical profession."

I am, Sir, yours, &c.,

Clement H. Sers.

Queen's Road, Peckham,
April 6th, 1894.

THE DEATH-RATE FROM HYDROPHOBIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—As a sequel to the letter to which you kindly gave space last week, I would ask if it is not marvellous that such statistics as these published in the *Times* newspaper should be accepted by the medical profession? France furnished in 1893, 1,470 people bitten by rabid (?) dogs, whilst the world of foreigners, Spaniards, Greeks, Indians, and Belgians, combined, figure at the modest number of 178. England sent only 23 patients, in spite of all that was done to push the treatment by the lay press. You will observe there are no Germans! Did the Teutons prefer to die sooner than accept the aid of a Frenchman? Are there no rabid dogs in Germany? *Risum teneatis, amici.* What are the French people thinking of to allow rabid dogs to flourish to such an extent and to bite so many French subjects? Why not imitate those countries which send so few patients? Perhaps France prides itself on having its capital as the hostelry of rabies.

The following are the statistics to which I refer, as having appeared in the *Times* a few days ago:—

"The current issue of the *Annales de l'Institut Pasteur* gives a full return of the work done there last year. It appears that 1,648 persons were under treatment, and that six deaths occurred. But in two cases the first symptoms of hydrophobia appeared before the treatment had been completed, so that they cannot be fairly included in the rate of mortality, the decrease in which, since M. Pasteur began his treatment eight years ago, is well shown in the following table :—

Year.	Number of Persons Treated.	Number of Deaths.	Rate of Mortality.
1886	2,671	25	·94 p.c.
1887	1,770	14	·79 p.c.
1888	1,622	9	·55 p.c.
1889	1,830	7	·38 p.c.
1890	1,540	5	·32 p.c.
1891	1,559	4	·25 p.c.
1892	1,790	4	·22 p.c.
1893	1,648	4	·24 p.c.
	14,430	72	·50 p.c.

Out of this total of 14,430 persons treated since the institute opened, 1,213 were bitten in the head, the number of deaths being 16, or 1·32 per cent. ; 8,032 on the hands, the number of deaths being 45, or ·56 per cent. ; and 5,185 on other parts of the body, the number of deaths being 11, or ·21 per cent. The 1,648 persons inoculated last year were made up of 1,470 French and 178 foreigners, the latter including 43 Spaniards, 35 Greeks, 23 English, 22 Belgians, 18 Egyptians, and 14 subjects of the Queen from India."

I am, Sir, yours, &c.,
B. Dubious, M.D.

◆

TREATMENT OF RHINITIS AFTER INFLUENZA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Referring to Dr. Atkinson's communication in your issue of April 4th, allow me to remark that the use of menthol in rhinitis, and especially in relation to influenza, was fully discussed by myself in a communication you did me the honour to publish in the Medical Press on January 20th, 1890, as well as in the two last editions of my work. Formulæ for snuffs, oily sprays, and inhalers of menthol are to be found in the Pharmacopœia of the Central London Throat, Nose, and Ear Hospital, published in the same year.

I would only add that the sequel to influenza referred to by Dr. Atkinson is by no means rare.

I am, Sir, &c.,
Mansfield Street, London, Lennox Browne.
April 7th, 1894.

Obituary.

DR. SAMUEL J. MOORE, OF GLASGOW.

We regret to announce the death of this gentleman, at the age of 60, on the 2nd inst. Ten months ago symptoms of his fatal illness began to show themselves, and since August last he was confined completely to bed. Although apparent improvement took place now and again for a short time in certain of his more urgent and painful symptoms, no real improvement towards recovery was maintained, and the disease steadily made progress. A native of County Antrim, where he was born sixty years ago, he journeyed to Scotland when a young man in order to push his way in the world, being destitute alike of money and friends. He taught as a schoolmaster in Paisley, and after the lapse of some years found himself in a position to begin the study of medicine in Glasgow University, walking thereto every morning from Paisley, a distance of seven miles. In 1863, he graduated as Doctor of Medicine with highest honours, and very soon after was appointed Pathologist to the Glasgow Royal Infirmary. About 1869 he was appointed Medico-Legal Examiner on behalf of the Crown for the Lower Ward of Lanarkshire, in succession to the late Sir G. H. B. McLeod. Dr. Moore had a very extensive consulting practice, and he was the intimate friend and trusted adviser of many of the best known and most influential families in the West of Scotland. He was never attached to the staff of any hospital, but gave his professional services gratuitously to the Widows' Friend Society, and did much to forward its interests. Dr. Moore was never married, and has by his will left the residue of his estate, after providing private legacies and bequests, for the foundation and support of an institution to be called "The Dr. Samuel Johnston Moore Convalescent Home for Nurses," the institution to be used as a temporary home for nurses whose health has temporarily or permanently broken down in the exercise of their profession, a preference to be given to nurses who have been directly connected with, and under the control of, the Glasgow Training Home for Nurses, 250 Renfrew Street. It is probable that the amount of the bequest will be at least about £45,000.

MR. D. W. CROMPTON, F.R.C.S., OF BIRMINGHAM.

Mr. Dickinson Webster Crompton, F.R.C.S., F.L.S., whose death took place at his residence, Edgbaston, Birmingham, was born 88 years previously, almost on the same spot where he has now died. He studied medicine at the Birmingham General Hospital, and subsequently in London at Guy's Hospital, and underwent a further course of instruction in anatomy in Paris. He became in 1829 a member of the Royal College of Surgeons and of the Apothecaries Company, and five years later he carried off the Jacksonian Prize of the Royal College of Surgeons. In 1843 he was made an honorary Fellow, and was elected on the staff of the Birmingham General Hospital in the same year. He was also a Fellow of the Linnæan Society, and was highly esteemed by all who knew him.

MR. J. H. KIMBELL, F.R.C.S., J.P., OF KNOWLE.

This gentleman died on the 2nd inst. at his residence in Warwickshire, after a short illness. His health had not been good for some months past, but his death was somewhat unexpected, pneumonia supervening on a severe cold which he had contracted in visiting a patient whilst he himself was suffering. Deceased was a justice of the peace for Warwickshire, Honorary Consulting Surgeon of the Midland Counties Idiot Asylum, Knowle ; a Fellow of the Royal College of Surgeons, chairman of Wheelor's Trust, and medical officer under the Factory Acts. He was about 75 years of age.

DR. ARTHUR HILL HASSALL.

Intelligence of the death of this gentleman reached us as we were at press. For some time past deceased had retired from the profession, and had been resident abroad. The earlier part of his career was devoted to scientific chemistry, and forty years ago his name first became publicly known in connection with his reports on "The Adulteration of Foods, Drinks, and Drugs." He followed the profession of analyst for the greater part of his life rather than that of a physician for obvious reasons, although he took the M.D.Lond. in 1851, and became a Member of the Royal College of Physicians of London in the same year. He may be said to have been the founder of the Royal National Hospital for Consumption, Ventnor, Isle of Wight, to which he continued to hold the honorary title of Consulting Physician. At one time Dr. Hassall was a voluminous writer on analyses, microscopy, chemistry, and allied subjects, his last work being "The Autobiography of a Busy Life," written in 1893.

◆

Medical News and Pass Lists.

Society for the Study of Inebriety.

The annual meeting was held on the 5th inst., the President, Dr. Norman Kerr, in the chair. Brigade-Surgeon Pringle commented on the Lewisham lunacy case, in which the simple treatment of an alcoholic insane inmate with the withdrawal of alcohol for a few days had led to a Local Government Board inquiry at a cost of £1,000. The inquiry showed that the medical officer was justified in certifying the man. This and other alcoholic mental cases revealed the want of a special provision for the curative treatment of such cases. Dr. Stanley Haynes read a paper on the etiology, prevention, and prophylaxis of intemperance, pleading for curative seclusion for the inebriate among other remedial measures.

Death under Chloroform at Bradford.

At the Bradford Town Hall last week—before the Borough Coroner—an inquiry was held into the death of William Ambler, a platelayer in the employ of the Lancashire and Yorkshire Railway Company. On Jan. 19th, he was struck by a train he was endeavouring to avoid and sustained an injury to his foot. He was taken to the Bradford Infirmary, and on Monday last it was deemed necessary to perform an operation. In accordance with his request chloroform was administered, and it was while under its influence that death took place. Dr. Hime said the quantity administered (three drachms in ten minutes) was not excessive. The jury returned a verdict in accordance with the medical testimony.

Underground Bakehouses.

The Sanitary Authority of St. George's, Southwark, is carrying on a vigorous crusade against insanitary bakehouses. Many have been already closed under circumstances of a more or less revolting nature. In the course of a prosecution conducted last week by Dr. Waldo, the Medical Officer of Health, some disgusting details were produced in evidence. The bakehouse was in a basement approached by a long, narrow, dark passage, opening from which were two living rooms and a water closet. The only daylight that could possibly reach the bakehouse was through a window, but the glass was broken, and the window blocked and covered with a sack. The baker used this place for a laundry by day, and a mangle and pile of clothes stood on a small raised platform along with some sacks of flour. In the floor, beneath the water tap, was a sink trap, plugged with a rolling pin, with a view to preventing the constant reflux of sewage. Such disclosures must sooner or later rouse the authorities into action. Last week a reference to Dr. Waldo's recent paper on the bakery question was made in the House, and a question asked upon the subject.

An Exemplary Punishment of a Dealer in Bad Meat.

The Commissioners of Sewers last week prosecuted a cattle dealer and slaughterman, living at Chelsea, for sending to the Central Meat Market two sides of beef and other parts of a cow which were totally unfit for human food. The facts of the case were clearly proved. The defence was of that nature which can be described as nothing less than an impertinent quibble. Fortunately the Alderman of the Bench was equal to the occasion. He soon ascertained that the defendant had been warned once before for committing a similar offence. Without hesitation, therefore, he imposed a fine of £80 for the two summonses, with the alternative of two months' imprisonment.

Berlin Society of Obstetrics and Gynæcology.

The Jubilee Festival of this Society will be held in a sitting of three days in May. The British Gynæcological Society has appointed Mr. Lawson Tait, its senior past President, to represent it at the meeting.

Pharmaceutical Society of Ireland.

The President and Council of this Society have appointed Dr. Ninian Falkiner, A.B., M.B., F.R.C.P.I., &c., Professor of Botany and Materia Medica in the Society's School. Dr. Falkiner has been one of the Society's examiners for some years, and he has resigned that post—in which he has given great satisfaction—in order to be eligible for his new appointment.

University of Aberdeen.

At the graduation ceremony on Friday last, April 6th, the distribution of medals, prizes, and certificates in the Faculty of Medicine for the Winter Session, 1893-4, took place. The following is the list of successful students:—

University Gold Medals.

Fife Jamieson Memorial Gold Medal in Anatomy—William Cockburn, M.A. Keith Gold Medal for Systematic and Clinical Surgery—Andrew G. A. Thomson, M.A. Shepherd Memorial Gold Medal for Systematic and Practical Surgery—William G. Grant. Matthews Duncan Gold Medal in Obstetrics—Peter Macdonald, M.A. Edin.

The following were winners of Class Prizes for Anatomy:—

Joseph A. Thomson, J. E. Esslemont, James H. Scott, John W. Milne.

Practical Anatomy.

Joseph A. Thomson, and Wm. Ironside Moir.

Chemistry—First Year's Students.

Silver Medal—Alexander Ogg, M.A. Bronze Medals—William Law Marr, M.A., James Moir, Charles C. Slorach, James C. Philip.

Second Year Students.

Silver Medal—Peter Edward, M.A. Bronze Medal—Thomas Snowball, M.A.

Physiology—Junior Division.

Medallist—R. G. Henderson, M.A.

Senior Division.

Medallists—George A. Reid, Alexander Fenton, M.A.

Surgery—Senior Division.

Medals and Highest Honours Certificates—Charles H. Dyer, Henry E. Smith, M.A., William Cockburn, M.A., William Murray, M.A., James S. Warrack.

Junior Division.

Medal and Highest Honours Certificate—John A. Rose, M.A.: Highest Honours Certificate—William H. Clark. Shepherd Gold Medallist—William G. Grant. Keith Gold Medallist—Andrew G. A. Thomson, M.A.

Clinical Surgery—Case-taking.

Bronze Medallist—William Cockburn, M.A.

Practical Surgery.

Medal and Highest Honours Certificate—Alex. H. Mackie, M.A.

Materia Medica—Senior Division.

Medal and First Class Certificate—George Cowie. Second Class Certificates—J. A. Mearns, P. Henderson.

Junior Division.

Medals and First Class Certificates—A. H. Lister, B.A., W. G. Grant.

Midwifery.

Matthews Duncan Medallist—Peter Macdonald, M.A. Prizemen and First Class Certificates—John H. Goodliffe (Senior Division), Alex. Don, M.A. (Junior Division), Robert Cruden, M.A., George A. Gibb.

Practice of Medicine.

First Class Honours—Alexander Don, Silver Medal and Certificate; A. D. Kelly, R. Cruden, P. Macdonald, and C. E. F. Owen-Snow Bronze Medals and Certificates.

Pathology—Senior Division.

First Class Honours—J. H. Goodliffe and L. O. Crosswell.

Junior Division.

First Class Honours—J. A. Black, Alexander Don, Alexander Low, A. L. Cobban, Robert Cruden, George A. Troup, George Thomson, A. Archibald, George Bruce, W. E. G. Duthie, Peter Macdonald J. M. H. Macleod, W. C. Hossack, and Thomas Irvine Bonner.

Zoology (New Ordinances)—Junior Division.

Prize and First Class Certificate—John J. R. Macleod, W. Ironside Moir, John Wishart.

Beyond the awards of prizes and medals a very large number of students received first-class certificates.

The following candidates having passed the necessary examination, received the degree of M.D. on April 5th, 1894:—

Davidson, George, M.A., M.B., C.M.; Illingworth, Thomas W., M.B., C.M.; Keith, Arthur, M.B., C.M.; Morton, William John, M.B., C.M.

Note: The thesis of Arthur Keith was considered worthy of "Highest Honours," and that of William John Morton of "Commendation."

The following received the degrees of M.B. and C.M. on same date:—

Archibald, Alexander, M.A., Astin, Wilson, Barnes, Ernest, Barraclough, Herbert, Beaton, Frank, Black, James Alexander, M.A., Brown, George Wilson, M.A., Cobban, Alexander Lee, M.A., Collier, Joseph Henry, Cowie, Charles George, M.A., Croswell, Louis Oliver, Cruden, Robert, M.A., Don, Alexander, M.A., Fairweather, Alexander Ferrier Angus, Findlay, John Sawyers, Gibb, George Alexander, Goodliffe, John Henry, Grant, George Cowie, Henderson, Albert, M.A., Heppard, William James, Hossack William Cardiff, Justice, David Fraser, Keith, William Milne, Kelly, Andrew Davidson, Low, Alexander, M.A., Macdonald, Peter, M.A., MacHardy, Donald Chisholm, MacLeod, John MacLeod Hendrie, M.A., Marr, John Smith, Milne, John Glanville, Mitchell, Peter, Patterson, Joseph Henry, Pieris, William Christofiel, Reid, Alexander W., Reid, G., Salmon, J. L., M.A., Saunders, B., Smith, R., Thomson, G., Thomson, W., Trotter, R. M., Troup, G. A., Turner, R., M.A., Wace, R. H.

The following candidates have passed the examinations for the degrees of M.B. and C.M., but will not graduate until they have attained the necessary age:—

Edmonston, William C., Laing, James S., Macpherson, James, Owen-Snow, Charles E. F.

Graduation Honours—Honourable Distinction.

The following gentlemen graduated with Honours:—

Peter Macdonald, M.A., Alexander Don, M.A., James A. Black, M.A., William Thomson, William C. Hossack, Robt. Cruden, M.A.

The Diploma in Public Health was conferred on:—

Arthur Lodge Patch, M.B., C.M., Surgeon-Major, I.M.D.; Wilfrid W. Pearse, M.B., C.M.; Hugh Ross, M.B., C.M.

Notices to Correspondents, Short Letters, &c.

GENERAL PRACTITIONER.—It is undeniable that the effects of the opium habit can be induced in young children by means of the persistent administration of paregoric, soothing syrups, &c. Among the symptoms are diarrhœa alternating with constipation, stupor, restlessness, especially when the drug is left off, diaphoresis, scanty urine of high colour, perhaps containing albumen and emaciation.

BOSTON EDUCATION.

SCENE - Photographer's studio in Chicago.—Enter lady from Boston, with baby.

Lady—"Good morning. I wish to have my child's portrait taken."

Photographer—"Certainly, madam. This is the little man, is it? Coo-koo! Bless um, little tootsee wootsees! Too-ka-love um Kchee!"

Boston Baby—"Mother, will you kindly inform me whether the deplorable condition of this person is due to permanent dementia or spasmodic and intermittent insanity. Kindly proceed, sir, and make as creditable a likeness as lies within your apparently limited capacities."—*Exch.*

MEMBER OF THE ELEVENTH INTERNATIONAL MEDICAL CONGRESS.—We believe that Professor Zakharin, of Moscow, is the leading consultant in Russia. He attends the Czar, and has been Professor of Clinical Medicine at Moscow for thirty-five years. Our correspondent will be surprised to hear that this Russian consultant is reported to have made a fortune of £200,000 by his profession.

DR M. C.—Dr. Klein, in experimenting on the infectivity of tuberculosis, has had guinea-pigs kept in cages in the ventilating shaft at Brompton Hospital, with the result that general tuberculosis was produced in the majority of the animals.

Meetings of Societies, Lectures, &c.

WEDNESDAY, APRIL 11TH.

LARYNGOLOGICAL SOCIETY OF LONDON.—At 5 p.m., Discussion on the question of Anæsthetics in Operations for Post-nasal Adenoid Growths.

WEST LONDON HOSPITAL (Hammersmith).—At 5 p.m., Mr. MacAdam Eccles: Head Injuries. (Post-Graduate Lecture.)

HUNTERIAN SOCIETY.—At 8.30 p.m. Clinical Evening. Dr. William Ettles: Buphthalmia.—Dr. Arnold Chaplin: General Glandular Enlargement.—Dr. Arthur Davies: Leucodermia.—Dr. Fred J. Smith: (1) Charcot's Joint Disease; (2) Cerebral Tumour.—Sir Hugh R. Beevor: Myxœdema —Dr. Stowers: Unusual Syphilitic Eruption.—Mr. J. F. Woods: Cases illustrating Treatment by Suggestion. The President will also show cases.

THURSDAY, APRIL 12TH.

BRITISH GYNÆCOLOGICAL SOCIETY.—Specimens.—Dr. Routh: The Conservative Treatment of Diseases of the Uterine Appendages.

NORTH LONDON MEDICAL AND CHIRURGICAL SOCIETY.—At 9 p.m., Dr. C. E. Beevor: On a case of Cerebral Tumour, with Remarks on certain Degeneration of Nerves and Consequent Symptoms (with lantern illustrations).—Mr. C. B. Lockwood: A case of Enterectomy and Intestinal Suture after Strangulated Hernia; Recovery.

ROYAL INSTITUTION.—At 3 p.m., Mr. F. Seymour Haden: The Etching Revival.

FRIDAY, APRIL 13TH.

BRITISH LARYNGOLOGICAL AND RHINOLOGICAL ASSOCIATION.—At 2 p.m., Dr. J. Macintyre: The Use of the Phonograph in Teaching and Practice. Mr. Geo. Stoker will open a Discussion upon the Expediency of Tracheotomy as a Preliminary to Thyrotomy for the Removal of Foreign Bodies from the Larynx. Cases will be shown by Dr. W. M. Whistler, Mr. F. Marsh, Mr. J. C. Wilkin, and Mr. Mayo Collier. Pathological Specimens will be shown by Dr. J. Macintyre and Mr. Wyatt Wingrave.

CLINICAL SOCIETY OF LONDON.—At 8.30 p.m., Dr. Finlay: A case of Abscess of the Spleen.—Dr. T. J. Maclagan: Cases of Myocarditis.—Mr. Arbuthnot Lane: Cases illustrating a more Effectual and Scientific Treatment of Fracture of the Tibia and Fibula than that in common use.—Mr. G. R. Turner: A case of Pelvic Enchondroma.—Mr. R. W. Parker: A case of Strangulated Femoral Hernia complicated by Volvulus, with especial reference to the Continuation of Obstruction after Herniotomy.

Vacancies.

Bury Dispensary Hospital.—Senior House Surgeon. Salary £100 per annum, with board, residence, attendance. Applications and testimonials to the Secretary on or before April 16th.

Cancer Hospital, Fulham Road, S.W.—House Surgeon. Salary £50 per annum, with board and residence. Applications and testimonials to the Secretary on or before April 16th.

Flintshire Dispensary.—Resident House Surgeon, Salary £120 per annum, with furnished house, &c. Applications and testimonials to the Secretary on or before May 15th.

Metropolitan Asylums Board.—Assistant Medical Officer for Eastern Fever Hospital. Salary £15 per month, with board, lodging, and washing. Applications to the Clerk of the Board before the 13th inst. (See advert.)

Newcastle-on-Tyne Dispensary.—Resident Medical Officer. Salary £250 per annum, with furnished residence. Applications and testimonials to the Hon. Secretary on or before April 20th.

Nottingham.—Assistant Medical Officer (unmarried) to the Coppice Asylum for Private Patients. Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications and testimonials to Dr. Tate on or before April 14th.

West Riding Asylum, Wadsley, near Sheffield.—Fifth Assistant Medical Officer. Salary £100 per annum, rising £10 a year up to £150, with board, &c. Applications and testimonials to the Medical Superintendent on or before April 17th.

Wirral Children's Hospital, Woodchurch Road, Birkenhead.—Resident House Surgeon. Salary £50 per annum, with board, lodging on the premises, and washing. Applications and testimonials to the Hon. Secretary on or before April 24th.

Appointments

BARROW, A. S., M.R.C.S Eng, L.R.C.P.Lond, Assistant House Surgeon to the Taunton and Somerset Hospital, Taunton.

CADDY, D. J., M.B., F.R.C.S., Surgeon to H.M. Colonial Medical Service.

CAMPBELL, P, L.R.C.P., L.R.C.S.Ed, L.F.P.S.Glasg., Medical Officer of Health for the Pontypool Rural Sanitary District.

CONRAN, P. A., L.R.C.P., L.R.C.S.E., Assistant Colonial Surgeon at the Gold Coast, Colonial Medical Service.

CROCKER, J. T., M.B., Ch.B.Vict., L.R.C.P.Lond., M.R.C.S., Medical Officer of Health for the Borough of Eccles.

CROWTHER, T., M.D.Aberd., M.R.C.S., Medical Officer of Health for the Luddenden Urban Sanitary District of the Halifax Union.

CLAYTON, W. K., M.D.Brux., L.R.C.P., L.M., L.R.C.S.Edin., Medical Officer of Health for Wakefield

FULLER, E. B., M.B., C.M.Ed., F.R.C.S.E., Medical Officer of Health for the City of Cape Town, South Africa.

ISARD, O. H., M.B., C.M.Ed., Assistant House Surgeon to the District Hospital, West Bromwich.

LEWIS, E. W., M.R.C.S.Eng., L.R.C.P.Lond., House Physician to the West London Hospital.

PARKER, J. E., L.R.C.P.Irel., M.R.C.S., Medical Officer to the Ince Local Board, and also Medical Superintendent of the Board's Infectious Diseases Hospital.

STIKE, P. H., M.R.C.S., L.R.C.P., House Surgeon to the Bucks County General Infirmary, Aylesbury.

SUTTER, R. B., M.B., C.M.Aberd., M.R.C.S., L.R.C.P.Lond., House Surgeon to the West London Hospital.

TAYLOR, A., M.R.C.S.Eng, L.R.C.P.Lond., Resident House Surgeon to the Royal Infirmary, Glasgow.

TWYFORD, W., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Audlem Sanitary District, of the Nantwich Union.

WALLER, T. H., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Infirmary, Chelmsford.

Births.

DREW.—April 3rd, at 4 Broad Street, Oxford, the wife of Arthur John Drew, F.R.C.S., of a son.

HUDSON.—April 7th, at Vine House, Cobham, the wife of Arthur By. Hudson, M.R.C.S., L.R.C.P., of a son.

KELLY.—April 5th, at Highbury Grove, N., the wife of Charles E. M. Kelly, M.R.C.S., L.R.C.P., of a daughter.

LANGRAN.—April 2nd, at the Lawn, Axminster, Devon, the wife of Wm. Langran, L.R.C.P.Ed., of a son.

SMITH. April 4th, at Hillside, Henfield, Sussex, the wife of G. J. Malcolm Smith, M.D., Hurstpierpoint, of a son.

Marriages.

BLIGH—LAFONE.—April 3rd, at SS. George and Mary, Cockington, Torquay, William Bligh, M.D., B.S., M.R.C.S., L.R.C.P., to Lilian Josephine, daughter of the late William Lafone, of Monte Video.

CRAWFORD—MCHARDY.—April 4th, at the Cathedral Church of St. Mary, Edinburgh, William Thomas Crawford, M.B., C.M., of Worksop, Notts, to Dora, elder daughter of Lieut.-Colonel McHardy, Royal Engineers, Prison Commissioner for Scotland.

DEANE—PRALL.—April 3rd, at All Saints', Carshalton, Edward Deane, M.R.C.S., of Caversham, Reading, to Emma Elly, eldest daughter of the late Dr. Prall, of West Malling.

HUNTER—FIELDEN.—April 2nd, at Nutfield Church, Surrey, William Hunter, M.D., M.R.C.P., of 54 Harley Street, London, W., to Beatrice, youngest daughter of the late Joshua Fielden, Esq., M.P., of Nutfield Priory, Surrey.

VOELCKER—ENGLISH.—April 3rd, at Sutton-at-Hone Church, Kent, Arthur Francis Voelcker, M.D., M.R.C.P., son of the late Dr. Aug. Voelcker, F.R.S., to Katharine Isabel, daughter of the late J. T. English, J.P., of Bradford Manor, N. Devon.

Deaths.

BARSHAM.—March 28th, at Weybourne, Bournemouth, Barsham, M.R.C.S., L.R.C.P.Lond., late of Bagshot, Surrey, aged 32.

BROWN-SEQUARD.—April 1st, at his residence, Rue Francois, Paris, Professor Charles Edouard Brown-Séquard, aged 77.

CARTE.—April 2nd, at Allahabad, India, Surgeon Captain Lindesay Carte, Army Medical Staff, third son of Wm. Carte, J.P.

CREWE.—April 2nd, at The Priory, Milton, Portsmouth, Alfred Godley Crewe, M.D.

GRAY.—April 4th, at his residence, Millvale House, Newry, Henry Gordon Gray, M.D., J.P., aged 86.

KIMBELL.—April 2nd, at the Manor House, Knowle, Jonathan Henry Kimbell, J.P., F.R.C.S., aged 74.

MAYBURY.—March 30th, at Holly Lodge, Richmond, Surrey, Augustus Kingston Maybury, M.D., aged 79.

MOORE.—April 2nd, at 15 Blythswood Square, Glasgow, Samuel Johnston Moore, M.D.

VERTUE.—April 2nd, at Red House, Southwold, Suffolk, Francis Henry Vertue, M.R.C.S., J.P., aged 72.

WALSH.—March 28th, at his residence, Worcester, Thomas W. Walsh, F.R.C.S., aged 77.

SOME PRACTICAL OBSERVATIONS
ON THE
EXAMINATION OF AN EAR
AND THE
ÆTIOLOGY OF AURAL AFFECTIONS.

By H. MACNAUGHTON JONES, M.D., M.Ch., M.A.O. (Hon. Cau.), F.R.C.S.I. & E.

(*Continued from page* 382.)

PART II.

I WOULD here urge that in every case of deafness not due to an accumulation of wax in the outer ear passage, or in those cases in which some recent exciting cause does not point to an obvious explanation of the symptoms, the first examination of an ear should include the most careful estimation of the hearing distance, by conversation, synchronous duplex sounds, the acoumeter, watch, and tuning fork.

The result of such testing should be recorded, relatively, for both ears, and should always be conducted with the back of the patient turned towards the examiner. This examination should likewise include a thorough investigation of the membrane in its different segments, the auscultation of the tympanum, the condition of the naso-pharynx, including the appearance of the turbinate bodies, and the permeability of the nasal passages, with a general view of the oral cavity, tonsils, and pharynx.

It may be said that such an exhaustive examination is unnecessary in the case of the experienced otologist. This assertion I altogether deny, and those who, through pressure of cases or any other reason, slur over any necessary part of a first aural examination, are every now and then certain to overlook what may be the most potent factor in the production of the deafness or tinnitus.

And I will take this opportunity of insisting that there is no necromancer's art in the most thorough examination of an ear—the steps are the simplest in the extreme. Patience, gentleness, and caution are the important essentials in the process. If the steps I have just referred to be taken, the differential diagnosis of the seat of the deafness is fairly established at a first interview, for it covers the evidences of abnormality in the membrane, tympanic cavity, Eustachian tube, labyrinth, nasal passages, and pharynx.

Side by side with our knowledge of the history of the case, and those more remote constitutional or reflex sources of the mischief, it enables us also to arrive at a fairly correct prognosis. I say "fairly correct," for there is a class of case, and by no means a small one, in which it is impossible to assert that a certain degree of benefit, mayhap a considerable amount, will not follow upon an experimental line of treatment, until at least such has been tried for a short time. I refer to intra-tympanic injections, Faradisation or galvanism of the tubal muscles, paracentesis of the tympanum, "massage" of the mastoid, nasal and pharyngeal medication, with special internal therapeutical remedies. For it must be admitted that a given remedy operates with various results in cases in which it is not possible to draw any broad lines of distinction by the objective signs discoverable by examination.

Not long since, I saw a lady for the first time who previously had had advice from more than one surgeon. She was extremely deaf. The daughter of a distinguished musician and composer, she took great delight in music. Gradually being deprived of this, her great enjoyment, she became low-spirited and depressed. The result of a careful examination was not encouraging, and I came to the conclusion that there were such gross changes in the middle ear, attended by old Eustachian closure, that there was but little chance of improvement. This decision I conveyed to her, and to the medical relation by whom she had been sent to me. I offered, however, if she were willing, to try on a few occasions what effect would follow catheterisation of the tubes, warm intra-tympanic injections, and Faradisation of the tubal muscles. This I did before she left me, and the next day she returned to say that for the first time for years she had heard the birds chirping on the trees, and that the night before she had listened to and perfectly followed the score of an opera. This improvement was still further increased by subsequent treatment, and I know that, to the present day, she retains useful hearing.

I merely mention this case as one of numbers I could cite, in which, most unpromising response to aural examination and tests has been disproved by giving a trial to what, at first sight, appeared to be a very hopeless line of treatment. On the other hand, disappointing results frequently follow any effort to improve the hearing or relieve the tinnitus. Therefore, it is always well to clearly and candidly explain to patients that the proposed steps are more or less of an experimental nature.

Nor must it be overlooked that, while the degree of improvement, if any, may be very slight, there is a fair proportion of cases in which further deterioration of hearing may be prevented by establishing a better state of equilibration in the tympanum through attention to the Eustachian tube and its muscles, and by securing more perfect ventilation of the tympanic cavity. This should always be distinctly explained to a patient threatened with progressive deafness.

From what I have said, it can be inferred that such therapeutic measures as the use of Politzer's inflator, with catheterisation of the Eustachian tube, are necessary in the first examination of certain cases. I do not, of course, include here, though it must occasionally be tried in order to give a correct prognosis, the application of the artificial membrane when defective hearing is due to a perforation of the drumhead. The trial of the effect on the tympanum of suction through a tube placed in the external meatus, is likewise a step which is not to be omitted.

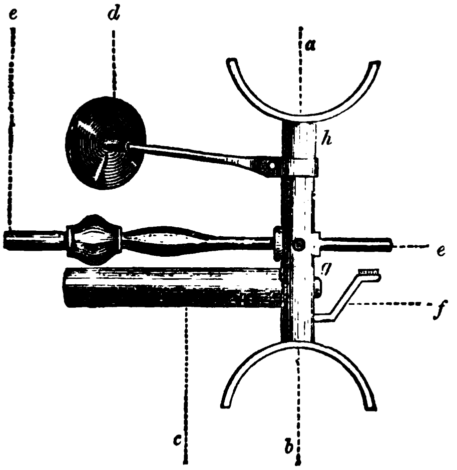
We turn now to some points in the examination of an ear, to which I would draw more special attention. Affections of the auricle are so obvious in their distinctive features that there is but little trouble in their recognition; and herpes, lupus, eczema, and malignant disease are sufficiently characteristic. I have never seen a case of primary syphilitic affection of the auricle or in the meatus, though such has been recorded, and condyloma is also extremely rare. I have seen one case of epithelioma. It finally destroyed the auricle, and ended in death.

There is one differential diagnosis which has to be carefully made. I refer to that between othæmatoma of the auricle and perichondritis. Of the latter, I have met with but one true case. This was a lad sent to me some some years since by Dr. Wm. Slimon. He had been subject to epileptic fits. The swelling, which came on gradually, involved the pinna. It was dark in colour, and very similar in appearance to that of the so-called "insane" ear. The concha was not engaged. There had been, however, in this case, from the onset, attacks of most severe pain, and other evidences of inflammation. On aspirating it, a semi-purulent and serous fluid was drawn off. This ultimately became quite purulent, and was evacuated by free incision, the cartilage being found bare. There was none of the subsequent shrivelling as is often seen in othæmatoma, and with antiseptic dressings the patient recovered. The hearing was not affected.

Now as to the examination of an ear. There are a few practical points bearing on the successive steps that have to be taken, and to which I will briefly refer. I think it well in every instance to first ascertain what the hearing power is with either ear, by conversation, the acoumeter, the watch, and the tuning fork. The two points as to the hearing of conversation in company, or when travelling, should be particularly inquired into. I habitually test the differentiating power by means of two clocks which have different ticking sounds. I find that, by many patients, only one of the two is heard, and this I always regard as an unfavourable sign.

With children we have to be extremely careful in judging of the hearing power from their replies. They must not be allowed to see either the watch or acoumeter where these are used. I find it a good plan to turn the child's face to the wall at some distance off and walk gradually towards him, at the same time striking the acoumeter and telling him to turn quickly round when he hears any sound. This plan can be tried with a repeating watch. Other little tricks of deception will sufficiently test the accuracy of the child's replies.

Politzer's acoumeter is not, I think, as frequently used as it ought to be in this country. Having tried it habitually for years, I have found it a most valuable aid in estimating the hearing distance. It also enables us to delicately test the necessity for contact in the convection of sound, and this at different points in the area around the auricle.

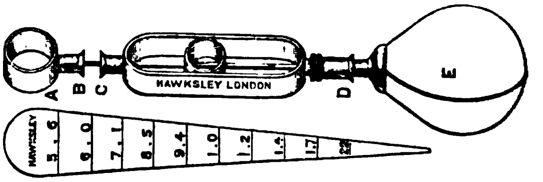


ACOUMETER.
a and *b* semicircular vulcanite ends of pillar for fore-finger and thumb; *h*, vulcanite pillar; *c*, steel cylinder; *e e*, steel lever hammer which strikes on the steel to *g*; *f*, vulcanite check; *d*, brass plate at end of the steel pin, which in the more recent instrument passes through the vulcanite pillar for 2½ inches. This plate is placed on any spot around the auricle so as to test the perception of sound by conduction. [I apologise for printing this cut, but I do so as I find so few are acquainted with the appearance or use of the acoumeter.]

The best manner of using the acoumeter is to make the patient stand with his back to the surgeon, at the same time that he closes the meatus of one ear firmly with the thumb. The examiner, standing at some distance, ascertains the point when the click of the instrument is heard with the open ear, walking gradually up to the patient for this purpose. The same plan is then pursued with the other ear. It is better in the first instance not to allow the patient to see the appliance or to know its use, and to merely ask if he hears any sound.

It would be too great a demand on space to enter here into the deductions to be drawn from a complete examination with the tuning fork. The steps of such a test, and the conclusions which may, in a certain proportion of cases be drawn from its application are fully entered into in the *Practitioners' Handbook of the Diseases of the Ear and Naso-Pharynx.* Suffice it to say that, as a means of differentiating disease of the labyrinth or auditory nerve from gross changes in the middle ear, the tuning fork is an essential help.

But long experience and constant use of it has made me doubt the accuracy of many of the earlier conclusions I arrived at with regard to its diagnostic value in middle ear abnormal conditions, and I am at present collecting evidence to bear on this point. The fork should be tried on the head, with both ears open, and with either ear closed. Also it should be held at a certain distance from the outer ear, and the comparative loudness of the note which is heard with each ear ascertained. I do not here speak of those extreme cases in which it has to be applied to the teeth, or to the area immediately surrounding the middle ear. With a Galton's whistle we may test the higher degrees of acuteness of hearing.



Galton's whistle for testing the higher degrees of hearing. The scale accompanying the whistle marks the number of vibrations. This will be shown by the length to which the piston, A, is withdrawn. The scale is inserted between B and C.

In the able paper which appeared in this journal by Dr. Ogston, in 1890, the fact was pointed out that there is around the auricle, in certain cases of deafness, an area of "touch deafness," especially where there is effusion into the labyrinth, and that there is considerable interference with the hearing. In the same paper he showed that the hearing distance varied according to the angle at which the source of sound was placed, in regard to the meatus, in the horizontal or vertical planes, the point of most distinct hearing being below the ear.

One thing has to be remembered in connection with improvement of hearing. In degree, this is often quite different as regards conversation and such tests as the watch and acoumeter. Increase in hearing the former is sometimes effected and maintained, while little, or but very slight, difference is perceived in the latter. This is specially worthy of recollection in cases of progressive deafness, in which periodical attention to the ear, when once a healthier state of the Eustachian tubes, and the tubal muscles has been secured, will at least tend to preserve this conversational power. It may be accepted as a general rule that hearing of the acoumeter, limited to contact, and a negative result with the tuning fork placed on the head, indicate disease of the auditory nerve, independent of such symptoms as vertigo, tinnitus, or sickness.

The whole question of tinnitus and the differentiation of its causes, as well as the prognosis to be given in its varying forms, is too wide a subject to enter upon. But we may briefly lay stress on these practical points which assist us in arriving at a conclusion :—

1. To seek for any collateral evidences of cerebral or auditory nerve lesion.
2. To search for any signs or symptoms of distant sources of reflex irritation. (*a*)
3. To examine the heart and great vessels.
4. To note the character of the noise. If it is unilateral or bilateral, its periodicity or persistency, the time of its greatest aggravation, as to whether it is heard loudest at night on lying down, or in the early morning ; whether it is accompanied by deafness, and if so, if the deafness was the first symptom, or *vice versâ*.
5. To ascertain if the noise be associated with vertigo, attacks of migraine, or sickness, and, in the first instance, if these symptoms occurred suddenly, or whether deafness and tinnitus preceded for some time the attacks of vertigo.

Limiting, as I do, in common with many others, true Ménière's affection to the occurrence of a sudden hæmorrhage into the labyrinth, and the consequent seizure, the reason for this latter inquiry is apparent. I take for granted that in all cases of tinnitus, these preliminary inquiries, to which I referred in my first paper, will be made. Elsewhere (*b*), I have entered more fully into the differentiation and causation of tinnitus.

◆

HOW CHRONIC SKIN DISEASES WERE AFFECTED BY THE GREAT AND CONTINUOUS HEAT OF LAST SUMMER. (*c*)

By A. SCOTT MYRTLE, M.D.,
Harrogate.

Before dealing with the subject I am down on the agenda for, I must ask you to take into consideration the fact that all the cases which come under the care of the profession in Harrogate are not only chronic but very old and obstinate ; cases which have lasted for months, oftener for years, during which they have been treated by the most celebrated dermatologists in this country, and in a large number of instances have also undergone a course of mineral waters and baths at home and abroad. Another point I must touch on —skin diseases during the past forty years have greatly increased in proportion to other ailments, and whilst the peculiar features or symptoms (this is particularly the case in eczematous conditions) have remained unchanged, their behaviour under treatment has at all events in my hands altered in a most unaccountable manner.

Forty years ago and long after, the treatment I found most satisfactory and successful is no longer possible, the local applications I entirely depended on then were highly stimulating crude preparations of wood-tar, strong mercurials, soft soap, huile de Cade, sulphur, caustic potash, and iodine, these single or combined were had recourse to not only in this country but on the Continent, and with the best results. Gradually I found them becoming less and less effective, then mischievous, and so was led to employ less active measures. About this time coal-tar came to the front, but it was impossible to make use of it as a local application to the skin on account of its insolubility, this difficulty was overcome in 1860. In the *Journal of Practical Medicine and Surgery* (Parisian) of that year I found an article entitled " Saponified Coal Tar applied to domestic and medicinal purposes." Dr. Jules Lemaire, apothecary to the hospitals in Paris, gave an account of its preparation and how he made use of it first as a deodoriser and destroyer of all offensive dead vegetable and animal matter, and as an effectual parasiticide. This led him to apply it to foul ulcers and discharges, ozæna, impetigo and anthrax. I was so struck with the wonderful results recorded that I at once made use of saponified coal-tar in every chronic case of skin disease that presented itself, and the result not only astonished me but delighted my patients, after some years I found I could not continue this treatment, skins resented it ; fortunately at the same time the introduction of phenic acid and its various products, salicylic acid, resorcin, aristol, and creolin afforded most valuable additions as therapeutic agents in dealing with the skin, still these were of a highly stimulating nature, and lately I have found in many cases great good follow the use of less potent dressings, such as boric acid, menthol, chloral hydrate, and dermatol. We thus see that apart from climatic conditions in skin affections presenting the same appearances, I, and I think most specialists have found it necessary to change our lines of treatment from one of a powerfully stimulating nature to one less active and at the present time to depend more and more on gentler measures often purely sedative.

I have always held that most of the commoner skin diseases, eczema in all its varieties, psoriasis, urticaria, prurigo, and herpes do not arise from any alteration in the blood, from diathetic conditions, or from invasion of the parts affected by any bacillus or micro-organism whatever, the most recent theory advanced, but that they are caused by certain changes which have taken place in the skin itself, and that these changes have started with irritation of nerve filaments this speedily destroys or alters that condition of cell life which is necessary for the healthy performance of those morphological functions which are constantly going on in one of the most complex structures of our bodies. With these preliminary remarks I shall very shortly tell you what I observed regarding the way in which chronic skin diseases were affected by the heat of this year.

In the month of June I was struck with the scarcity of vesicular and the abundance of papular forms of eczema ; there was hardly a single case where I could discover any active exudation, or the usual amount of subcutaneous infiltration, all were dry, scaly, and intensely irritable, even such parts as the upper and inner thighs, generally sodden, were void of moisture ; as the season advanced and the heat increased a number of cases of lichen turned up, where the whole of the trunk back and front, as well as the upper and lower extremities presented an uniform light red brick colour, there was no break on passing the hand over the surface, it felt hot, harsh, uniformly level, and was especially on the back shiny or glazed ; when you took up a fold between finger and thumb it was greatly thickened, the slight infiltration underneath was firm, elastic, and this with the thickening of the skin inter-

---

(*a*) On the 12th inst. I was consulted by a gentleman for tinnitus. There was some accompanying deafness. The noise was of a pulsating character. There was a history of gout. The cardiac sounds were feeble. He had an anæmic appearance. There were no objective signs of aural affection. On examination of the urine it was found to contain about one-fourth of albumen. He had no suspicion that there was renal disease.

(*b*) " Noises in the Head and Ears," 1891.

(*c*) Read before the Yorkshire Branch, British Medical Association, held at Harrogate, November, 1893.

fered with the free movements of the joints; the itching was described as maddening, especially during the night, with all this there was no constitutional disturbance, no fever, appetite good, and although sleep was greatly interrupted, the strength remained undiminished; if they went out for a walk during the day they had to return quickly on account of the fearful itching, divest themselves of every article of clothing, and walk or sit perfectly naked. Ordinary remedies were of no use, and even the most soothing applications such as boric acid, chloral, camphor, and menthol, all in form of solution, relieved only for a time.

Cases of lichen, such as I have described, are very rare, before this year I have met with very few, one, or at most two in twelve months, and the only way in which I can account for their frequent occurence last season is by reason of its great and continued heat, this in persons predisposed to eczema produced first great activity of the sweat glands, in time these got exhausted, the ducts inflamed, became occluded, hyperæmia of the whole skin was established, and speedily gave rise to the symptoms I have described; I found men and women equally affected, the youngest was 46 and the oldest a vigorous lady of 78, and oddly enough she made steadier progress than any of my other patients, and except for a little itching now and again when she got tired, in six weeks went home perfectly well. Cases of prurigo were also of much greater frequency here, the skin on superficial examination presented nothing very remarkable, it looked a little dingy, on passing the hand over the surface the sub-epidermic papules felt slightly enlarged, perfectly separate from each other, and gave you the characteristic rasp; patches on arms and legs were torn and bleeding from the severe scratching they had undergone, especially during sleep, the itching was intolerable, and the general expression of the face was one of far greater anxiety and suffering than that of those affected with lichen, the starved condition which invariably exists in the pruriginous, whether young or old, may in part account for their utterly miserable look.

I fully expected that I should have met with some cases of lichen tropicus, prickly heat, but in this I was disappointed.

Cases of psoriasis were as common as ever, but the heat agreed with them, there was less hyperæmia, the scales smaller, less adherent, and improvement under the usual treatment was more rapid. The pustular forms of acne went through their stages with greater rapidity than I had ever witnessed, and the blocked sweat ducts in acne punctata were very easily emptied by direct pressure. I did not observe any change in the different forms of urticaria, but simple erythema of the face and neck was greatly aggravated. Syphilitic eruptions did exceedingly well during the exceptionally hot weather. I was surprised at the improvement manifested in almost every case after a very short course of treatment. One of rupia very severe, where the incrustations were large and numerous, arms, legs, chest, and even the forehead were studded with the limpet shell formation. On removing these the ulcers were deep phagedænic, and intensely painful, the mucous membrane of nose, throat, mouth, and tongue was studded with small ulcers, so that for weeks he had been unable to eat, but he evidently had been able to drink, as he was bordering on delirium tremens. If ever there was an unpromising case here it was, but in two months with the exception of two painful ulcers on the back, he was as well as he ever will be. Whilst he was under treatment the thermometer never was below 74° during the night, and ranged from 80° to 84° during the day, and this to my mind proved of great therapeutic value.

At the meeting in Newcastle I heard for the first time of the employment of thyroid extract in psoriasis and the astonishing results brought about in a few days. I confess I had my doubts on the subject, but determined to put this new remedy to the test. I thought that the cases of lichen where the whole skin had something in common with the pachydermatous condition of myxœdema afforded a fair subject for the experiment. To every patient I prescribed one of Allen & Hanburys' thyroid tabloids containing 5 grs. of the extract morning and evening. I gave the same to every patient suffering from prurigo and psoriasis, I watched the result most anxiously, days passed, a week, two weeks, without the slightest benefit which could be attributed to the extract, so I gave it up, and for this reason Dr. Byrom Bramwell stated that improvement was visible in one case after a single dose, and that in two or three days inflammation and swelling had greatly diminished, and in five there was a shedding of scales, the redness and itching had subsided, and at the end of a three weeks course the eruption had in great part disappeared. Since then I have tried thyroid in chronic eczema but failed to observe any benefit from its employment. That it has a direct power in restoring health to the thickened skin in myxœdema I am fully convinced, but the conditions here are very different to those occurring in psoriasis, eczema, or lichen.

◆

FURTHER NOTES
ON THE
THERAPEUTIC ACTION OF ORGANIC EXTRACTS.

By CHARLES FORBES, M.D., C.M., D.P.H.Cantab.,
Late Surgeon, Wassa Gold Mines.

It is here sought to prove that most of the "organic extracts" (shall we call them "albumoses") before producing their therapeutic results on different portions of the body (*cf.* M. Marie, Société Médicale des Hôpitaux, Feb. 23rd, 1994), if only in the case of the thyroid gland tissue, act on the nervous system, on its various parts, and in different ways and through nervous system on *nutrition*, in the case of the thyroid gland extract acting chiefly on the neuro-vascular economy strengthening and regulating it (*Medical Times*, March 3rd, 1894). And at the same time I hinted that the pituitary extract:—

(1) To a certain extent undoubtedly supplies or replaces the functions or functional secretion, &c., of the pituitary body whose unimpaired activity is seen to be co-existent with mental well-being as well as even life itself. (Dr. Andriezen states that destruction or disease of pituitary body causes depression of temperature, &c., and death in a short space of time (*British Medical Journal*, vol. 1, 1894). And

(2) Further, that although this extract may be used in some of the morbid states where thyroid extract sometimes benefits, sometimes fails, acts more exclusively on the tissues of the central nervous system, diminishing or aborting various pathological processes tending to, or having already produced, certain forms of mental disease. At the same time pointing out that in acromegaly these extracts may be used interchangedly. Dr. Byrom Bramwell's reports on cases of acromegaly, &c., somewhat confirm the above statement (*British Medical Journal*).

However, our clinical data at present are too meagre to work out further a strict differentiation as to when one extract should be used and when the other. Is it, however, a fact that thyroid juice will cure myxœdematous symptoms whether associated with mental disease or not, but the treatment must be kept up long after an apparent cure or a relapse will often take place, however, when symptoms have subsided the dose can be much diminished. Their learned discoverer, the late Dr. Brown-Séquard does not seem to have produced differentiating evidence clear enough for our purpose and his method, though his statements have led us up to an important point, is open to some objections which will prevent its gaining ground in England. To say nothing of its comparative failure when tried on patients with various nervous diseases by Drs. Ferrier and Buzzard (*Lancet*, Feb. 3rd, 1894, p. 263). However, Alombert-Goget, *Lyons Médicale*, Nov. 12th, 1893, says that Brown-Séquard's fluid when given in sufficient doses has seemed to give some result in two classes of cases: (1) locomotor ataxia, (2) delirious epilepsy.

Not only was general nutrition improved, but mental condition wore a more favourable aspect.

(1) In ataxic patients there was disappearance of lightning pains, delirium subdued, and temperature regulated, and increase of vitality in every respect.

(2) In epileptics fits were modified in form, and though they were perhaps slightly increased in number, patients' general condition was improved.

The nature of these objections to this method is foreign to the object of my present paper which is simply to disperse or partly so the obscurity surrounding not only these preparations themselves but their uses. We have, however, to thank Dr. Brown-Séquard and his school for leading many eminent physicians and therapeuticians to apply scientific means of investigating the practical medical and surgical uses of these extracts, We appear thus in old-fashioned proverbial phraseology to be "putting the cart before the horse," but as their discoverer has not laid down the exact scientific action of these remedies or the changes (if any) they undergo in the body before giving rise to their physiological action. Up to the present time we have had to be content with the fact that these extracts have in certain cases caused the abatement of certain symptoms. An original paper dealing with part of this subject was read by Dr. R. W. Felkin, Feb. 17th, 1894, before the Obstetrical Society of Edinburgh and reported on in *Edinburgh Medical Journal*, Feb. number. Although he does not attempt any explanation as to the exact therapeutic action of the extracts he deals with, namely, *orchitic* and *cerebral* extracts, he owns his preference to the tabloid form as being well borne and taken without difficult or unpleasant results by all his patients. *Note.*—In this I agree with him, and give such reasons as appear most valid why they should be used in preference to hypodermic injections and administration by the mouth of the ordinary organic liquid extracts:—

(1) That the extract in a dried form and compressed is more permanent and reliable, and can be kept a length of time which the liquid extracts cannot, as such organic solutions are prone to undergo fermentative changes.

(2) That they are portable and their dose is easily regulated.

(3) That the glands, tissues, &c., used in their composition have, I believe, been first examined by pathological experts.

(4) These substances are, I believe, also prepared *en masse* with antiseptic precautions, thereby insuring uniformity of drug and safety of patient.

(5) That patients do not object to taking them.

(6) That these tabloids do not cause nausea and diarrhœa to anything like the extent the liquid organic extracts have been proved to occasion.

Dr. Felkin premises that he was led to employ the two above extracts by either seing or hearing of certain cannibal practices which occur among natives of Central and West Africa, and also the practice of semen drinking. He brings forward notes of cases which he has treated: (1) with cerebral, (2) with orchitic extract, with undoubted success, and hints further that both these extracts might be useful in treating some cases of complaints little susceptible hitherto of cure connected with generative system. *Note.*—The only other reliable form except the tabloid is by taking the fresh glands, &c., which although advised by Dr. Marie, of Lyons (quoted *Lancet*, 1894), is regarded as positively disgusting by most patients.

Dr. Felkin says the dose should be small and increased afterwards. I here tabulate briefly some of his results:—

(1) *With cerebral extract (cerebrinin)*:—

(1) Pseudo-hypertrophic paralysis benefited, (2) epilepsy three cases much improved, (3) acute alcoholism cured in a week, (4) irritability, nervous exhaustion, anæmia, increase of weight, marked improvement, (5) two cases of inveterate insomnia, cure, (6) general debility improvement, (7) neurasthenia benefited, (8) nymphomania and anæmia at commencement of menstruation, cure.

(2) *With orchitic extract*:—

(1) Melancholia, &c., after ovariotomy, remission of mental symptoms. In these cases he states cerebral extract is also useful; (2) epilepsy, (3) in all nervous diseases connected with generative troubles.

In my opinion, going further than this physician, orchitic extract would be useful in all the morbid processes following masturbation, which evil is fearfully wide-spread. I consider the paper interesting, but I must take exception to his indifferent uses of these extracts in the same cases which only seems to add to the obscurity already preventing a comprehensive differentiation of these extracts, and somewhat misleads us as to their several therapeutic values and uses, which points can only at present be proved clinically and by deductions carefully drawn from reported facts. Dr. Church, *loc. cit.* suprâ, complains that he has not paid sufficient attention to the "ferments" as the active principles of gland tissues, and instances extractum pancreatis (Fairchild ?), which he says is valuable in cases of glycosuria associated with pancreatic disease. An impure form of this extract was used by Dr. Harley in a case of gall-stones with some benefit. How? Most probably by preventing the retention of cholesterine in the gall bladder and interfering with chemical action necessary to the production of these stones, which actions are notably under the governance of the central nervous system (sympathetic ?). Of the nervous system cholesterine is either a chemical product or a constituent. Here again would appeared to be another proof of my (now more than) theory:—*That all the albumoses indicated as therapeutically and physiologically active are so directly through the agency of one part or another of the nervous system (central).* These I class under A:—

Examples.—Thyroid, pituitary, thymus, cerebrinin, orchitic, testicular, ovarian, and pancreatic extracts. B. Under this I class all those extracts which seem to act simply as foods to repair general metabolic waste; these are extracts of bone, red marrow (Dr. Dixon Mann), and muscle. The action of thyroid tabloids I have discussed elsewhere (*Medical Times*, March 3rd, 1894).

I will now pass on to those of *thymus gland*. These are useful in the wasting diseases of early infancy, especially in those where there is either disease or derangement of the lymphatic glands. This gland would seem during its period of activity, limited to early life, to enrich the plasma of the blood by a large production of lymph-cells and their active constituents, *cf.* Herr Kossel's lecture on "Lymph Cells" reported in the MEDICAL PRESS AND CIRCULAR, Feb. 28th, 1894, p. 229, who derives the lymph cells used in his valuable experiments chiefly from thymus glands. Its intimate connection with the lymphatic glands is thus clearly made out. It is also closely related to the nervous system (trophic centre), but the exact working of this relation there is not much clinical evidence to support or to assist us in formulating the functions of the gland with any degree of certainty. Another extract which appears to resemble cerebrinin in action is *nerve* extract used as a hypodermic injection in neurasthenia

(*British Medical Journal*, 1893, p. 1,321) before passing on from Class A. I must mention *suprarenal* extract, which was by a sort of homœopathetic evolution set up as a cure for Addison's disease, &c., suffice it to say we have no clinical proof of this result.

Class B.—The food-like extracts I may dismiss without further remark. Now I will conclude in trusting that these few notes may lead some of my professional brethren to work in the same direction; in which, however imperfect the results at present must necessarily be, sufficient evidence is now forthcoming to rescue these agents (organic extracts) from the stigma of being empirical, which they have been deemed simply through some ignorance as to their practical utility, forgetting the while that our British Pharmacopœia contains many drugs such as the purgatives and cardiac tonics whose reputation rests on no more scientific basis than clinical observations of their effects.

◆

MODERN PROJECTILES

FROM A

HUMANITARIAN POINT OF VIEW. (a)

By Professor KOCHER,

Berne.

The reason why ancient Rome, whose hospitality we are now enjoying, acquired the immortal glory, which it maintained through the classical ages till our own times, is to be found in the warlike character of its first inhabitants, in the *Virtus Civis Romani*. Notwithstanding the great progress which has taken place in the field of intellectual activity, it is still the case, that those nations become arbiters of the world, that are always ready to sacrifice their life and all they possess for liberty, truth, and justice.

Military service is a duty, which extends to all citizens, and, therefore, all take an interest in the necessary and inevitable consequences of war. Women and sanitary associations vie with each other to diminish the sufferings of the victims, as also the Red Cross, whose representatives showed us two years ago, in this same city the splendid results obtained by them.

But all this is of no use (I speak simply from a surgical point of view) if modern firearms bring such devastation in the contending armies, while they should only put *hors de combat*, if they mutilate instead of simply wounding. Twenty-five years have not passed since it was universally recognised that modern firearms cause enormous damage in the human body. This general opinion is confirmed by the recent communications of Démosthène, Chauvel, Nimier, Bogdanik Sklissowsky, Morosow, and Trauber, by the observations of Kabars, and finally by the interesting experiments executed by order of the Prussian Minister of War by Dr. Schjerming, all of which show the terrible effects of modern bullets. After this must we wait further improvements or must we resignedly accept the conclusions of Surgeon-General Dr. Von Koler and of Dr. Schyenning, namely that with the new rifle life must absolutely be lost?

The object of war between civil nations is not, as amongst savage people, to kill the greatest number of combatants, but to disable the enemy and to oblige him to abandon the field. Nevertheless, there are many unexpected deaths caused by injuries to vital organs. But the modern guns greatly surpass this scope, because they tear or destroy the tissues of the body, exposing the victim to the risk of losing his life even from the effects of injuries primarily not of necessity vital, and which the re-establishment of the normal function. Guns have become real explosive fire-arms.

The degree of intensity of the explosion gradually augments with the increase of velocity, while we can only talk of hydraulic pressure in the case of maximum velocity and on parts like the cranium.

The effect is seen in its full intensity only if the distance is great enough, but also in open tin boxes, where the water is not hermetically closed, as in a hydraulic pump, a laceration takes place. It is, therefore, better to abandon the name of hydraulic or hydrostatic pressure, and to use that of hydrodynamic laceration.

I here will demonstrate the effect of explosions on flexible substances, such as soap or glass, in which we may with certainty establish, by means of comparative measures of weight and volume, whether we have to deal with a simple shock or with a missile that produces at its maximum velocity the maximum degree of dilatation.

In such cases, we find an augmentation in the explosive effect, even though there be no rotate or deformation, and we must recognise that the intensity of the explosion does not depend upon these factors.

The real nature of an explosion can only be understood if its effects are studied on a solid body. To this end, we can fire a bullet at a slab of stone, and we will ascertain that the shock transmits itself with great violence. The difference between a simple crack and a real laceration may very well be distinguished in a glass slab, if the velocity of the missile is not at its maximum, in which case a number of cracks are produced instead of a neat small hole. The best manner of observing the perfect analogy of the effect of dry explosion with those of dydrodynamic pressure on a tin box is to fill this box with small shot or pieces of stone.

The lecturer gave numerous illustrations demonstrating the analogy of explosion in dry and fresh bones. What is then the essence of the explosion? Kocher has been able to demonstrate by determining the velocity of the bullet fired at different objects, and also on the human body, that for maximum velocities a greater amount of active energy is lost than for the small ones. This augmentation in the loss of active energy is caused by the velocity being too great to penetrate the target, and by remaining longer imbedded in it produces an unequal shock. By means of experiment, it is possible to ascertain that the loss of velocity and active energy is greater in bullets of heavy calibre, and consequently the lacerations will be greater.

In order to understand the results produced by these arms, it is necessary to know the effect of the explosive projectiles, but unfortunately on this matter the opinions of most authors are very diverse.

I will here briefly describe the results of my twenty-five years of experience. The action of the bullets varies as the object which it strikes varies. We shall therefore distinguish three separate categories in the human body; elastic tissues, tissues rich in liquid substances, and rigid tissues.

In elastic tissues the bullet does not explode, at least not immediately, even if fired out of the most modern rifle. Large lacerations of the skin are due to deeper explosions, such as those which take place in the vicinity of the bone, and without these external lacerations are not to be found. In some elastic tissues we can only observe the point of entrance and exit of a bullet whose initial velocity is of 600 to 750 metres; we cannot trace any aperture at all as the tissues after having been forced aside, resume their former position.

The effect of any explosion may be observed with far greater facility in tissues which contain an abundance of liquid substances, and is naturally more terrible in those tissues whose composition is of that nature. Brisch was the first who had recourse to hydrostatic pressure in order to demonstrate the effect of an explosion in the cranium; Grafeuil, Heppner, and Küster applied the same principle to epilepsy, and I have been able to show by means of numerous experiments the general importance of liquids in the tissues. The action of hydrostatic pressure may be demonstrated on tin boxes containing substances more or less rich in water. The effects of the explosion differs greatly if the box contains fresh horse-flesh instead of dry, and the same is true of damp or dry cotton or saw-dust.

(a) An Address delivered before the International Medical Congress at Rome, April 4th, 1894.

Here are some elastic laminæ that present a very small hole when the velocity of the bullet is small, while enormous rents are made by it when the velocity is at its maximum.

These violent effects are caused both by leaden and by steel bullets; it is therefore impossible that they should be produced by the breaking up of the bullet, as it is proved that steel does not undergo any alteration of shape.

The following conclusions were added by the lecturer from a humanitarian point of view:—

1st. The cause of the laceration cannot be avoided because it depends upon the augmentation of velocity.

2nd. It is necessary then to reduce the extent of the laceration which occurs.

3rd. By diminishing the area struck:—

(*a*) reducing the calibre of the projectile to 5·6 cms.;

(*b*) preventing the fracture of the projectile by giving it more compactness especially in the point;

(*c*) by making the anterior extremely sharper so as to increase its strength of penetration;

(*d*) by augmenting the rotation so as to prevent the oblique penetration.

Further experimentation will demonstrate if from a humanitarian point of view it will be necessary to use again very small copper projectiles or projectiles with steel coating and point. *The results already obtained* by the introduction of the steel coating shows:—1. Even after the worse results there are no more muscle and lung lacerations. 2. The fracture of bones, is totally limited in extent and intensity, again the aperture of exit is, according to the experience of Coller and Schjerming, reduced for 200 metres distance from 2 to 3 centimetres while before it varied from 7 to 14. One of the greatest improvements from a medical point of view is the reduction of the size of the aperture, as the healing of the wound is then materially facilitated and dangerous complication are rendered more difficult. But the extraction of large fragments of bone, and injuries to vital organs such as the heart, the brain and the lungs will always make numerous victims, and consequently in the next war hundreds of soldiers will lose their lives on the field of battle.

But the great mass of our youth that courageously marchs into the grim jaws of war will be protected by a new Pallas armed with the shield on which shines the Red Cross.

Selected Prescriptions and Therapeutic Notes.

108.—Local Dressings for Burns:—

(I)

℞ Cocainæ hydrochlor., pars j;
Acid. carbolici, partes ij;
Acid. borici, „ x;
Glycerini, „ xvij;
Aq. destill., „ lxx.
M.

(II)

℞ Acid. borici, partes iv;
Iodoformi, „ ij;
M.

(III)

℞ Acid. borici, partes iij;
Iodoformi, „ ij;
Aristol, pars j.
M. Dr. Robinson.

109.—For Laryngismus Stridulus:—

℞ Chloral. hydratis, ʒss;
Pot. bromidi, ʒij;
Syr. tolulani, ℥ss;
Aq. menth. pip., ℥iss.
M. A teaspoonful every half hour.

110.—Useful in General Infantile Eczema:

℞ Hydrarg. ammoniati, gr. x;
Acid. carbolici, gr· viij;
Ol. olivæ, ʒss;
Ung. petrolei,
Ung. zinci oxidi, āā ℥ss.
M. Apply two or three times daily.—Stelwagon.

111.-For Cancer of the Cervix Uteri:—

℞ Iodoformi, gr. xv;
Extracti opii, gr. viij;
Essentiæ bergamottæ, ♏x;
Ol. theobrom., ʒijss.

M. To make twelve suppositories; one to be introduced into the vagina when necessary.—Sinety.

112.—For Alopecia:—

℞ Quininæ sulphatis, gr. xl;
Tinct. cantharidis, ʒj;
Sp. ammon. aromatici, ℥j;
Ol. ricini, ℥jss;
Ol. rosmarini, ♏vij;
Sp. vini rect., ℥v.
M. Shake well before applying once a day.—Wilson.

113.—Chlorosis from Menorrhagia:—

℞ Sulphate of iron,
Ext. hydrastis canadensis,
Ext. of hyoscyamus.

F. s. a. Divide into 100 pills. Two to be taken at each meal. *From our French Correspondent.*

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, April 13th, 1894.

The Vice-President, Dr. Duffin, in the Chair.

A CASE OF PELVIC ENCHONDROMA.

Mr. G. R. Turner read notes of the case of a man, æt. 50, who was admitted into St. George's Hospital, March, 1890, with a tumour of eight years' growth. It was a large globular swelling on the inner aspect of the left thigh, extending into the perineum and groin. The circumference of the left thigh over the tumour was 29½ inches, as compared with 19 inches on the right side. The hip-joint and thigh moved freely, and were not implicated in the growth, which was attached to the rami of the pubes and ischium by a broad hard base. The patient was shown at the Clinical Society on March 14th, 1890, and the general opinion was that it would be very inadvisable to attempt to remove the tumour. In 1892 the tumour had steadily grown, and had extended into the perineum and ischio-rectal fossa, so as to press on the urethra and rectum, interfering very materially with micturition and defæcation. On these grounds, it was decided at all hazards to try to remove it. This was eventually done by cutting through the mass of the growth and removing it in halves after an ineffectual attempt to get at the base. The enchondromatous mass removed weighed upwards of seven pounds. The man made a good recovery, although a small portion of the thinned stretched integument sloughed.

Mr. R. W. Parker read notes of a case of

STRANGULATED FEMORAL HERNIA COMPLICATED WITH VOLVULUS,

his object being chiefly to draw attention to the subject of continued obstruction of the bowels after operation, and to elicit from members of the society the treatment most appropriate to this condition. His patient was a woman, æt. 44, who came under treatment on the 6th day of strangulation. She was very ill. Herniotomy was performed, and as the gut was gangrenous, an artificial anus was made, but no fæces escaped. Sixteen hours later, the abdomen being more distended, laparotomy was done. A volvulus was discovered and adjusted, immediately after which fæces began to flow from the artificial anus. The woman, however died in about twelve hours.

Mr. A. Barker said the paper illustrated one of the numerous difficulties that surrounded these cases of intestinal obstruction. Whether by observation on the living or post-mortem one was often struck by the small amount of twist that would suffice to effect complete obstruction of the intestinal canal. This fact suggested that it ought to be easy to remedy the condition surgically. Under these circumstances he thought they ought not to have the slightest hesitation in opening the bowel in order to afford the necessary relief. He admitted that a doubt must often remain as to the precise nature of the obstruction, but under any conditions he urged that whatever its nature it might be dealt with by abdominal section, preferably by a median incision through which one had access to volvulus, *reduction en masse*, &c. The real difficulty was to make up one's mind early in the case to have recourse to surgical measures. He had never heard of a surgeon who had had occasion to regret having intervened too early, whereas it was but too frequent an experience to hear men regret having postponed their intervention. He questioned the necessity for allowing the bowel to escape from the abdomen, and asked the author what was his reasons for so doing.

Mr. R. W. Parker, in reply, explained that he was unable to arrive at a diagnosis of the nature of the obstruction without allowing the bowels to escape. He too had been struck by the slight amount of twist necessary to bring about complete obstruction and by the ease with which the displacement could be remedied. The operation had been performed within an hour of the patient's admission so that they could not be accused of losing valuable time.

Dr. T. J. Maclagan on

THREE CASES OF MYOCARDITIS.

A record of three cases in which inflammation of the muscular substance of the heart occurred in the course of acute rheumatism, without accompanying endo- or pericarditis, and in which the disease was diagnosed. In one which proved fatal the cardiac muscles were found to be dark, soft, and easily broken down by pressure between the finger and thumb. The points insisted on were the absence of any special physical signs by which myocarditis could be diagnosed; and the presence of delirium of a a low muttering type, and of muscular tumours which give the appearance of one suffering from delirium tremens. The gravity of the delirium as a symptom occurring in the course of acute rheumatism was pointed out. The complications to which it is generally due are hyperpyrexia, myocarditis, pericarditis, and pneumonia. In hyperpyrexia there is the high temperature to decide the diagnosis; in pericarditis and in pneumonia there are the physical signs. It may be stated generally that delirium occurring in the course of acute rheumatism which is not due to one of these complications, is symptomatic of myocarditis. Attention has been called by various writers to the occasional occurrence of sudden death in acute rheumatism. It is probable that latent myocarditis was the cause of such deaths. In one of the cases given death was sudden.

The President agreed that in view of certain symptoms attention ought to be directed to the possibility of a primary myocarditis more frequently than was at present the case. The administration of diffusible stimulants lay at the basis of the treatment of this condition, but he doubted the advisability of giving the salicylates. On the whole he would prefer the combination of alkalies and quinine suggested by Garrod.

Dr. Hale White pointed out that myocarditis had been recognised as a possible complication of rheumatism for a long time. Myocarditis might and often was associated with either peri- or endocarditis. The author was fortunate in that his cases were free from complication, and were therefore the more interesting. He agreed that in well-marked myocarditis one ought to be cautious in giving the salicylates, and he referred to a case in which moderate doses thereof marked the onset of the downward course.

Dr. David W. Finlay on a case of

SPLENIC ABSCESS WITH SECONDARY ABSCESSES IN THE LIVER —DEATH FROM PYÆMIA.

The patient was a domestic servant, æt. 20, admitted into the Aberdeen Royal Infirmary, under his care, on 7th October, 1893. The family history was unimportant. As to personal history, she had been delivered of a child in the previous April, since which her health had not been good. Three months ago she had an attack of "pleurisy" with which she was laid up for about a week. The attack for which she sought admission began on September 28th, and consisted of pain in the left side with shivering and sickness. On admission she complained of pain and difficulty in breathing with a short dry cough. The symptoms and physical signs generally were suggestive of pleurisy with effusion, but the maximum cardiac impulse was found in the third interspace well within the nipple line, the sounds being loud and slightly roughened but otherwise normal. Two days after admission it was noted that the pain in the right side had been severe and the temperature had reached 103° on one occasion, and 105° on another. Further fluctuation in the temperature and occasional sweatings led to the belief that the supposed effusions was purulent, and on October 13th the exploring syringe was used being introduced in the eighth interspace below the inferior angle of the scapula. Only a few drops of blood were withdrawn. Subsequently, four other exploratory punctures were made in various situations with negative results. She gradually lost strength and became anæmic and emaciated. Ultimately she had attacks of delirium, the abdomen was distended and tympanitic, and she complained of pain in the head extending down the neck. She gradually sank and died on November 21st. At the post-mortem examination the spleen was firmly bound to the diaphragm and surrounding parts of adhesions, and at its anterior end encapsuled with adhesions there was a collection of thick greenish pus about the size of an orange. On section, the lower end of the spleen was found to be the seat of several abscesses containing curdy pus communicating with the purulent collection just described, the remaining two-thirds of the organ being healthy. The uterus and other pelvic organs were healthy, as was also the heart; but the right lobe of the liver was riddled with recent abscesses varying in size from a pea to a walnut, and the left pleura contained about ʒij of blood-stained serum, the base of the left lung being adherent to the diaphragm. The brain was not examined. The case at its commencement so strongly suggested purulent effusion that it was a matter of surprise that so many exploratory punctures failed to reveal any, the only alternatives which suggested themselves being malignant disease of the lung and subphrenic abscess. The presence of certain points as regards the former, and the absence of others as regards the latter, rendered either of these alternatives improbable, and beyond the diagnosis of suppuration from the rigors, rise of temperature and sweating no conclusion was arrived at. As to the etiology of the splenic abscess this was altogether obscure. Possibly an injury, or some septic condition connected with the pregnancy the evidence of which had disappeared, might have accounted for the beginning of the disease in the spleen; the abscesses in the liver were obviously secondary.

The President referred to a case of acute abscess of the spleen which had recently come under his observation. The patient was a young woman about eighteen years of age, who came in with pleurisy at the base of the left lung. There was also dulness at the apex of that lung, which was thought to be tubercular. In the course of a day or two the patient was attacked by an agonising pain along the eighth rib, which obliged her to remain absolutely motionless. She lay on her back with the left lower limb drawn up, and when the abdomen below the ribs was palpated she visibly winced, and the sensation was followed by nausea. She died ten days later, and post-mortem had found ulcerative endocarditis and a spleen one and a half times as large as normal and tied down to the diaphragm by adhesions. There were two small abscesses in the upper part of the organ and extensive pleuritic adhesions above.

Mr. **Arbuthnot Lane** read a paper on the

OPERATIVE TREATMENT OF OBLIQUE SIMPLE FRACTURES OF THE TIBIA AND FIBULA IN CERTAIN CLASSES OF LABOURERS.

He asserted that the receipt of such an injury too often entailed on the skeletal machinery of the individual an enormous financial depreciation of its value, and in not a few absolute ruin, since a considerable portion were incapacitated from pursuing their usual occupation and were obliged to follow other and usually less remunerative pursuits, while others were so unfitted for work as to be thrown on the rates or rendered dependent on charity. He believed that the average financial depreciation of the labourer as a machine amounted in such injuries to nearly as much as 70 per cent. of his original value, which, if true, is simply disastrous. This he described as being due to an alteration in the lines of pressure through the several joints of tho lower extremity, resulting from the somewhat complicated deflection of the lower fragments from their original relationship to the upper. In consequence of this alteration in the manner in which pressure is transmitted, insecurity and pain are experienced in the several joints, this being most marked in the articulations of the ankle and foot, and increasing with the age of the individual. Pathologically this is represented by a progressive mechanical arthritis in the several joints. Other conditions, as œdema, eczema, and ulceration may exist in consequence of the limited action of the muscles and joints. Such being the case, Mr. Lane argued that to pursue the present mode of treatment was highly improper, since by operative measures entailing a minimum of risk to the life or limb of the patient, the fragments could be brought into apposition and so retained with perfect accuracy with the result that the skeletal mechanics of the individual remain as perfect after the injury as they were before. This result is brought about by cutting down on the fracture of the tibia and exposing the broken ends freely, removing any soft parts or fragments of bone intervening between the sectional surfaces, bringing these surfaces into accurate apposition, partly by traction on the foot, partly by means of elevators, and partly by means of lion forceps, by which last instrument apposition is continued till holes have been drilled and the bony surfaces brought together immovably and most forcibly by the introduction of steel screws. Such operative measures at once relieve the patient from the pain which may result from the movement of the fragments on one another and from the tension and discomfort due to the extensive extravasation ef blood between and into the tissues; they shorten the duration of the period during which the man is incapacitated from earning a living, since bony union is rapid and perfect, and, what is of most importance, they leave his skeletal mechanics in the condition in which they were before the accident. Mr. Lane read the notes of three cases which he had operated on in the same week. In them the results obtained by operative interference were extremely satisfactory, since the fragments had been retained in accurate apposition and had united perfectly, the outline of the bones being normal. He pointed out that even when the fracture is thoroughly exposed the surgeon may experience the greatest difficulty in obtaining accurate apposition of the fragments, but he believed that with the judicious application of traction to the foot, combined with the use of elevators, lion forceps, and steel screws, in but a very small proportion ef cases would the surgeon fail to obtain perfectly accurate apposition, and in that small number the displacement would be very trifling indeed. In the face of these facts he considered that a surgeon was not treating such fractures properly if he confined himself to making use of manipulation and splinting without first informing the patient fully of the imperfect mechanical condition which would very likely result and did not urge strongly on him the immense advantages he would derive from operative interference, the risks connected with which are very small.

Mr. Lane's paper was supplemented by a brief account of forty cases collected by Mr. F. J. Steward, which fully bore out the truth of the statements made.

Mr. **Horatio Symonds** said that he too had been struck by the unsatisfactory nature of the results obtained after the ordinary treatment of oblique fractures of the tibia and fibula, and he had tried the effects of driving in pegs and wiring the fragments. He used Thomas's knee splint fixed with three-cornered bandages instead of the ordinary back splint. He thought that the use of the usual vertical foot-piece was productive of great harm. He had adopted this course in several instances of fracture some months previously with satisfactory results.

Mr. **Gould** said that until the author had spoken to him on the subject he was certainly ignorant of the fact that the ordinary treatment of simple fracture of the tibia and fibula was attended by such terrible results, and he suggested that probably many other surgeons were similarly placed. If the results of the ordinary treatment were really so disastrous he agreed that it was incumbent on surgeons to devise some more efficacious plan of dealing with them, but at the same time he could not shut his eyes to the very great risks associated with converting a simple into a compound fracture, especially as most of these cases fell into the hands of general practitioners.

Mr. **Lane**, in reply, agreed that as to the actuality of these risks, and added that Mr. Hulke on being asked what was his estimate of the diminution of the financial value of men who had had this accident had voluntarily given an estimate which tallied with his own, viz., from 70 to 80 per cent.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Pathology.

Meeting held Friday, March 16th.

The President, **Prof. Alfred Scott**, in the Chair.

RENAL TUBERCULOSIS.

Mr. **Myles** showed the kidneys and intestines of a boy who had been under his care at the Richmond Hospital. His history was very vague, as the lad was dull and reticent, but he complained of pain over the pubes and incontinence of urine. His urine was normal in quantity, sp. gr. 1012, and contained pus. He was suspected to be suffering from stone in the bladder, but examination by the sound was postponed owing to his debility. He died suddenly four days after admission. On post-mortem examination his right kidney was greatly enlarged, and the cortex subdivided into cavities of about an inch in diameter filled with putty-like *débris*. The right ureter exhibited small tubercular ulcers along its entire length. The left kidney was only slightly enlarged, but was in a more advanced stage of tubercular degeneration, being converted into a mass of caseous material calcifying in parts. The left ureter was occluded, apparently from cicatricial contraction. The mucous membrane of the bladder showed acute tubercular infection, being studded with millet-seed tubercles. The small intestine similarly was acutely infected, most marked in the upper parts. The lungs were quite free from tubercles, and Mr. Myles pointed out the extreme rarity of this condition in the lungs under such circumstances, and the unusual manner in which a chronic process in the kidneys was succeeded by an acute process in bladder and intestines.

Dr. **Bennett** asked had the urine been examined for tubercle bacilli?

Dr. **Myles** replied that it had not, but that after death he had taken some of the *débris* from one of the cavities in the kidney and examined it. He found, however, only a few bacilli in it.

TUBERCULAR PERICARDITIS.

Dr. **Little** showed a specimen of pericarditis which had occurred in a woman who had, four months previously, suffered from typhoid fever, and who showed several caseating masses in the lungs, but who did not suffer either from rheumatic fever or renal disease.

Dr. **Bewley** described a section which he had made through one of the small nodules growing on the peritoneal surface of the intestine, at a place corresponding to the Peyer's patch. The floor of the Peyer's patch, which was devoid of mucous membrane, was formed of rather dense granulation tissue, and the little nodule attached to it was composed of fibrous tissue with a small mass of caseous material and in addition some giant cells. On account of these he thought the nodule was probably tubercular. He regarded the case as one of double infection, both typhoid and tuberculosis.

Dr. **SMITH**, who had seen the patient some three months previous to her death, described the illness from which she then suffered. She had an enlarged spleen and a well-marked crop of rose-coloured spots. She had also some pyrexia. Before admission to hospital she stated that she had a pain in her right side, and on admission a friction sound was discovered, and there was a localised patch of dulness corresponding to the caseous mass shown in the specimen. She passed through a course of typhoid fever, but she continued to have some pyrexia. She left hospital and came up several times afterwards complaining of cough and loss of flesh and appetite. He thought that it was exceedingly interesting to see a typhoid ulcer in process of regeneration. The mucous membrane had not yet had time to be spread over it, and it was very seldom one got an opportunity of seeing one in this stage.

Dr. **BENNETT** asked had any microscopic examination been made of the thickened pericardium?

Dr. **BOYD** said he thought the case looked like one of general tuberculosis. He was glad that Dr. Little had not described it as a case of idiopathic pericarditis. We cannot believe that inflammation starts without a cause.

Dr. J. W. **MOORE** advanced the theory that the case might have been one of pyæmia following typhoid fever. He said the mass in the lung might possibly be due to an embolus of a septic nature.

Dr. **JAMES LITTLE**, in replying, stated that as yet no microscopic examination had been made of the pericardium, but he hoped to have it done. He also said the mass in the lungs resembled in all respects to the naked eye a caseous mass, and not a portion of lung affected with embolus. There was also a caseous gland in the mediastinum.

SPLENO-MEDULLARY LEUKÆMIA.

Dr. **M'WEENEY** read a paper on this case, which was that of a man, æt. 50, admitted for obscure symptoms into the Mater Misericordiæ Hospital, under the care of Dr. Boyd. After detailing the results of modern research into the various cells commonly included in the class leucocyte, and the various granulations described by Ehrlich and his pupils, the speaker gave the results of his own examination of the blood of the case under observation. On admission the red discs were 67 per cent. of normal, and were to the leucocytes in the proportion of 8·8 to 1. During the patient's stay in hospital the red sank to 44 per cent., whilst the white corpuscles also showed a marked diminution, the proportion being now 1 to 35. Large myelocytes, often with eosinophil granulations, were very frequent, and the number of eosinophil cells of all kinds was much above normal. The mast-cells were numerous, but he could not with certainty confirm Ehrlich's description of the distribution of neutrophil granules. Nucleated red blood corpuscles, both normoblasts and megaloblasts were very numerous, especially the former, and the nuclei of the former were frequently found lying free, with circumstances that seemed to point to their extrusion from the cell. Their recognition was greatly facilitated by the marked metachromatism (with Ehrlich's acid hæmatoxylin and eosin) which they showed when compared with the nuclei of the leucocytes. The importance of this observation, as regards the development of the red discs, was discussed. Many of the nuclei of the nucleated red corpuscles presented so regularly lobulated an appearanae as to strongly suggest a somewhat obscured mitotic process in the rosette stage.

Dr. **BOYD** gave a short account of the clinical symptoms of the case on whom Dr. M'Weeney's observations had been made. The patient complained of breathlessness on exertion and feverishness, and of being unable to do his work. There was nothing abnormal about the heart or lungs or the alimentary canal. The patient had an enlarged spleen, a slightly enlarged liver, and was slightly anæmic. He lived in a marshy district, but never had any sort of malarial fever. The pains in his bones were very transient indeed. He considered the case might be one of leukæmia, and was greatly interested when it was found to be of the spleno-medullary variety. The patient was treated with arsenic and improved under it.

Dr. M'**ARDLE** asked Dr. M'Weeney had he ever examined the blood in cases of sarcomata? In some of these cases the patients complained of pains in their bones; spontaneous fractures took place sometimes in the red medullary portions of them, and the blood was abnormally pale. He thought there might be a connection between leukæmia and sarcomata.

Dr. M'**WEENEY** stated that he had not examined the blood of patients with sarcomata, but that the next time he got an opportunity of doing so he would.

PERFORATING WOUND OF PHARYNX.

Dr. M'**ARDLE** reported a case of perforating wound of pharynx, causing mediastinitis.

Dr. **MYLES** drew attention to the great tolerance the pharynx has of foreign bodies. He remembered a somewhat similar case in which the fatal symptoms likewise took some days to develop. A man came to hospital stating that he had swallowed a fish bone. He was able to swallow fluids but not solids. No probang was passed. Five or six days afterwards he became feverish and shortly died. A small fish bone was found to have perforated the pharynx and also the trachea. A mediastinal abscess had formed, and the patient had, in addition, purulent pneumonia.

The Section then adjourned.

◆

HARVEIAN SOCIETY OF LONDON.

MEETING HELD THURSDAY, APRIL 5TH.

The President, Mr. **GEORGE EASTES**, in the Chair.

CLINICAL EVENING.

DR. **LEONARD GUTHRIE** showed two infants, aged three and six months, who were suffering from

CONGENITAL RESPIRATORY SPASM.

It was a continuation of laryngeal inspiratory stridor and pharyngeal stertor which accompanied both inspiration and expiration. The condition had been almost constant since birth, but varied in severity. In the older child it was increased during sleep, stertor, however, being more apparent than stridor. In the younger the breathing became natural during deep sleep, but laryngeal stridor was present during light slumber. In both cases the breathing was rendered worse by sudden movements, draughts of air, bathing, or by any emotional excitement. In both there was marked recession of the episternal notch during inspiration; in the younger child there was also deep epigastric recession, and it was rapidly acquiring a pigeon breast. The dyspnœa caused no apparent distress, cyanosis was absent, cry and cough were natural. The pharynx as far as could be seen was healthy, and there was no nasal obstruction. The larynx had not been satisfactorily examined. There were no signs of atelectasis, but slight bronchial catarrh in both cases. Their general health was fairly good, the younger child, however, had had frequent convulsions. There was no family history of similar respiratory affection. In the absence of satisfactory laryngoscopic examination he was inclined to agree with Dr. Thomson in regarding the condition as a "developmental neurosis," or congenital inco-ordination of the thoracic, laryngeal, and pharyngeal respiratory muscles, perhaps dependent upon immaturity of the respiratory centres.

Dr. C. W. **CHAPMAN** had some years ago a case with symptoms similar to those in the condition present. Dyspnœa became urgent and tracheotomy was performed. A post-mortem three weeks later revealed numerous papillomatous growths scattered over the interior of the larynx.

In reply, Dr. **GUTHRIE** said that one infant had been treated with small doses of strychnine, and the other with bromide of potash in combination with cod-liver oil. Both had considerably improved, but the tendency in such cases was towards recovery. The malformation of the epiglottis described by Dr. Tees and mentioned by Dr. Phillips, had not been found in all cases, and, therefore, could not be regarded as the constant cause of the symptoms.

Dr. G. A. **SUTHERLAND** showed two cases of

GUMMATA OF THE LIVER IN CHILDREN.

The first patient, a girl, æt. 10, had been healthy as an infant, but when four years old had suffered from keratoiritis and disease of the bones of the nose and mouth, the evidences of which were still well-marked. The liver was much enlarged, and its surface was rendered uneven by hard round masses irregularly distributed. A soft fluctuating swelling was present over the left parieto-occipital region under the pericranium. The second case, a girl, æt. 15, also showed well-marked signs of hereditary syphilis in the eyes, nose, and ears. Two years previously she had a recurrence of acute specific disease as manifested by a gumma on the ninth rib, a swelling of the lower end of the left femur, and gummatous growths in the liver. She had been under mercurial and iodide treatment for two years, and her health was now good, while very slight traces of the gummatous formations remained. These cases illustrated some of the later developments of hereditary syphilis in children. They occurred frequently at or about the age of puberty, and seemed to delay the normal physiological changes of that period of life. Inunction had given better results than the internal administration of mercury, but the treatment in all cases must be prolonged.

Dr. Illingworth submitted that the reason why Dr. Sutherland secured better results by treatment with mercurial inunction with iodide of potash internally, than by solution of the perchloride alone internally, was that the iodide of potassium acted as a solvent upon the mercury absorbed, forming the solution of the biniodide. This solution being penetrant and easily eliminated was non-poisonous, and hence superior to the bichloride, which, as was well known, had been denounced by Tarnier for obstetric practice for that reason. That this was a valid contention (over and above his own experience of the biniodide since 1886 as a germicide and disinfectant) was shown by the prevention of mercurialism amongst mercurial plate-workers by the administration of small doses of potassic iodide at meal times.

PERSISTENCE OF BRANCHIAL CLEFTS.

Mr. F. J. Poynton showed a case of persistence of the third branchial arch on either side in an infant of fifteen days old. There were no other evidences of arrest of development in the child, nor was anything of the kind present in the mother or in her other child, aged three years. The remnant was most marked on the left side, and resembled an auricle. It was covered with some downy hairs and appeared to contain cartilage; on the other side there was only a slight prominence. No aperture could be detected on either side.

Dr. W. Hill made some remarks on the difficulty of finding an aperture in these cases of persistent branchial clefts and arches, and said that if a solution of salicylic acid were painted over the site of the supposed aperture, and perchloride of iron administered internally a purple colour would be produced where the aperture was.

Mr. Juler showed a child suffering from some

OBSCURE INTRACRANIAL LESION FOLLOWING MIDDLE EAR DISEASE.

Three years ago the patient had suffered from suppurative otitis media on the right side, followed by complete right facial palsy, and later by paresis of the right external rectus. Periodic attacks of vomiting preceded at first by occipital and afterwards by frontal headache accompanied these nervous lesions. Hearing is completely lost on the right side and sight in both eyes considerably impaired owing in all probability to the intense double papillitis that exists. The child has a staggering gait, keeping her legs separated and rolling from side to side as she walks. No anæsthesia is to be found anywhere, the sense of taste on the right side of the tongue, however, is quite lost. The motor power on the right half of the body is somewhat weaker than that on the left side. Muscle sense is impaired and the knee-jerks absent. With regard to the nature and the seat of the lesion Mr. Juler is inclined to believe that the trouble is a chronic abscess dependent on the ear trouble rather than a glioma, and that it is localised either in the pons or more probably in the cerebellum.

Dr. James Taylor said that the case was without doubt one of abscess or tumour in the cerebellum, the symptoms being so remarkably in accordance with that condition.

Dr. William Hill was inclined to think that the case might be one of subdural suppuration, and urged that the treatment was an exploratory incision.

Dr. Guthrie said that he had seen a case in which the symptoms were identical and in which death ensued. At the post-mortem no evidence of disease or tumour was found in the cerebellum but the lesion was in the region of the optic commissure.

Dr. Illingworth agreed with Mr. Juler and Dr. Taylor in their diagnosis; but considered that the differential diagnosis between abscess and cerebellar tumour would be facilitated by free incision of the tympanum, which had evidently become firmly cicatrised before the complete evacuation of the original abscess. He suggested that the incision be kept open so as to allow of the regular use of penetrant antiseptic injections, so that the "phagocytic efforts" of nature might be supported. At any rate the germs of putrefaction would thus be easily destroyed, whether Metchnikoff's high-flown theory were true or not.

Dr. Sydney Phillips showed a female, æt. 24, who had suffered from "paroxysms of pyrexia" each day since September, 1893, with a short interval. The chart for the last eight days showed a daily rise of temperature to nearly 103° with subsequent fall each day to the normal. There was a gumma on the right arm, a much enlarged spleen, and periosteal nodes on tibia and on olecranon process. The pyrexia had not yielded to treatment by quinine or by salicylates, and Dr. Phillips regarded the case as one of syphilitic fever resembling ague similar to that he had recorded in the Medical Society's Transactions, vol. xii, and in the *Lancet* for 1889.

Dr. James Taylor showed two cases of "Friedreich's Ataxy." Both patients were males, æt. 16, not in any way related. The first showed very well the characteristic deformity of the feet. There was no family history of any similar condition, but his mother was epileptic and he himself had had fits. The knee-jerks were still present. In the second case there was marked lateral curvature, the symptoms otherwise were usual, knee-jerks absent. A half brother of the patient, æt. 9, a son of the same mother but different father, had marked nystagmus without any other symptoms of ataxy. There was a clear family history of similar condition.

◆

THE HUNTERIAN SOCIETY.

Meeting held Wednesday, April 11th.

The President, Mr. C. J. Symonds, F.R.C.S., in the Chair.

Clinical Evening.

Dr. Ettles showed a case of Buphthalmos in a boy of 4 years, blind from birth, and read a summary of the condition.

Dr. Arthur Davies showed a case of Leucodermia in a boy of 11 years; the patches were roughly symmetrical, and chiefly affected the back.

The Presidnet showed a case of Lymphadenoma, with peculiar patches on the hands and feet, thought to be due to the use of arsenic.

Dr. Stowers showed (1) a case of Acne Varioliformis, and (2) a case of extensive Tertiary Syphilitic Patches resembling eczema.

Dr. Fred. J. Smith showed (1) a case of Cerebral Tumour with paralysis of both sixth nerves as the only localising symptom; (2) a case of General Paralysis of the Insane, closely resembling Disseminated Sclerosis; (3) a case of Charcot's Disease of the right knee-joint in a tabetic man.

Sir Hugh Beevor showed a case of doubtful Myxœdema with pitting of the hands; the symptoms had improved under thyroid treatment.

Dr. J. F. Woods showed several patients whom he had treated successfully by suggestion, including cases of toothache, melancholia, and severe neuralgia.

◆

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Tuesday, April 3rd, 1894.

Mr. Thomas Wilmot, M.R.C.S., in the Chair.

Mr. Horrocks read a paper on

ANAL TAGS.

The formation of the anus is sometimes incomplete, the proctodeum not reaching mesenteron, the septum remaining, such is a case of imperforate anus; generally the septum is completely removed, but frequently fragments remain at the junction where the squamous and columnar epithelia meet such fragments constitute the anal tags, the upper surface generally pouched formed by the mesenteron, the lower rounded formed by ingrowing proctodeum. Not uncommonly these tags become abraded by hard motion catching the upper surface, and a shallow ulcer results, which may or may not be painful according to its relation to superficial nerve filaments, it is generally painful on the passage of fæces, and secretes a thin discharge. These ulcers are usually situated above tags which are painful on pressure by irritation, they may go on to form a callous painful ulcer or fissure of the anus, the tag constituting the "sentinel" or "guard" pile. Internal *fistula in ano* has been noted as rising from these ulcers, probably due to septic infection from the fæces, this also explaining the frequency of fistula in the phthisical. In other cases tags may hypertrophy and be grasped by the sphincter, leading to varicosity of the hæmorrhoidal veins and external piles. The treatment is thorough stretching of sphincter, scraping of ulcers after search for fistula, and removal of the tags.

Dr. **Hermann Bronner** read a paper on

TREATMENT OF SIMPLE FRACTURE BY MOBILISATION AND MASSAGE.

He contended that in suitable cases one ought not to wait for osseous union before using the joint affected or proximal joints, but commence passive and active movements and apply energetic massage as soon as the eighth day after fracture, in order to prevent atrophy and stiffness. Such suitable cases were fracture in the proximity of the wrist and ankle-joints, and knee and elbow-joints, where the dangers of stiffness were great and where there was sufficient support rendered by other bones or little leverage exerted by movements. He quoted statistics by Landerer (Volkman's Series) and some cases of his own in support of this method, by which Landerer, for instance, claimed to restore a fractured radius to practical use for all except heavy work within a fortnight.

Mr. **Emerson** read notes of some

UNUSUAL CASES OF TYPHOID FEVER.

In one case a middle-aged man had a relapse which was followed by venous thrombus in legs and an extremely rapid pulse, the tachycardia persisting for three months, but the patient ultimately recovering. Another case, a girl of eighteen, after a relapse presented symptoms ascribed to peripheral neuritis and also a persistently rapid pulse.

France.

[FROM OUR OWN CORRESPONDENT.]

PARIS, April 14th.

GUAIACOL.

Dr. **Desplats**, Professor at the Medical Faculty of Lille, was the first to remark the antithermic effects of guaiacol when painted on the skin, but it appears that as a sedative, it also constitutes a valuable resource in the treatment of certain painful affections. Thus, guaiacol not only suppresses rapidly certain neuralgic pains so frequently met with in tuberculous patients, but also sciatica and rheumatism, where salicylate of soda and antipyrine had failed. However, the application of guaiacol in its pure state is painful in itself, and irritates considerably a delicate skin. For this reason M. Moissy mixes it with equal parts of glycerine, by which no inconvenience is felt. The dose to be employed is half a drachm, but the painting can be renewed as the sedative effect has passed away, that is to say, in about five hours. At the meeting of the Société Médicale des Hôpitaux, M. Balzer said that he had tried guaiacol in the treatment of orchitis with good result, in ointment (guaiacol vaseline). A burning sensation is felt for about ten minutes, after which the patient experiences a certain *bien être* which permits rest and sleep. Guaiacol has no resolutive effect on the swelling.

BERLIN, April 13th.

TESTICULINE.

At the meeting for Internal Medicine Goldscheider continued the discussion on Prof. Leyden's paper, which criticised Brown-Séquard's new remedy. Goldscheider thought this was a scientific novelty of some value. He referred to Furbringer's opinions that certain organs had a considerable influence over the whole organism. The removal of the testes produced undeniable disturbances, just as myxœdema induced cachexia strumipriva. He was of opinion that the secretion in both conditions had some powerful influence on the assimilation and nutrition of the body. In many cases we know that the secretion will produce toxic effects as bile and urea, and may not unlikely affect the system when other secretions are retained. He related a case treated with the gland which improved, but not being sure about the diagnosis would not press the recovery as entirely due to gland treatment. Another cure was treated with the same for six months without any beneficial effect. There was no doubting of the preparation. Carrying this glandular treatment a little further, pancreatic juice was applied in cases of diabetes without realising the object desired, although it was faithfully carried out by mouth and clysma for eight weeks. Any accidents that might occur were due to the dose where the incorporation of the drug was too rapid.

STRONGILUS GIGAS.

Lilien showed a case of pallisade worm, or strongilus gigas. The worm was one metre in length, and from its size was at first assumed to be a small serpent. Its principal abode was the kidney, more particularly the pelvis. It appears to have obtained admission as usual by the blood current, and having reached the kidneys, completed its growth in the pelvic portion of the kidney, destroying the pyramidal and internal portion of the organ.

AMYOTROPHIC LATERAL SCLEROSIS.

Senetor brought forward a case for the criticism of the Society who retained all the symptoms that are claimed by Leyden and Charcot for the explanation of this morbid disease. Charcot, 30 years ago, gave the name amyotrophic lateral sclerosis to a morbid condition characterised by paralysis and great weakness in the upper and lower extremeties, atrophy of the muscles, stiffness and contraction with increased tendon reflex. At the same time sensibility was retained as well as the normal function of sphincter and bladder. The affection tended to death by producing bulbar paralysis. Leyden, however, challenged this opinion, and still remains opposed. The primary change, according to Charcot, is a sclerosis of the lateral pyramidal column, and to this is added, at a later stage, atrophy of the ganglia in the anterior horn of the column. Leyden, on the other hand, maintains that this is erroneous, and that the diseases arise from progressive muscular atrophy, and that no primary lateral sclerosis exists. In the case showed by Senetor, a domestic, æt. 57, had been received into ward last May with all the symptoms of atrophic lateral sclerosis, viz., paralysis, great feebleness in upper and lower extremities, contractions, stiffness, increased tendon reflex, spinal muscular atrophy, with left stronger than right, and later having all the bulbar phenomena, unable to open mouth, while the eyes remained movable, no power to put out the tongue, and speech disturbed. For seven years past sensation in the arms and legs was abnormal, later giddiness and cramp commenced, and gradually increased till paralysis agitans ensued. After this the symptoms become more complex, with the amyotrophic lateral sclerosis. The patient retained perfect sensibility, electric tests showed no degeneration nor fibrillary contraction. Patient died after three months' confinement to bed with pleuro-pneumonia, atrophy of the kidney, and in the cord atrophy of a large number of the ganglia in the anterior horn of the cervical enlargement as well as the upper part of the dorsal. The blood vessels of the spinal column were congested, and in many places hæmorrhage of the blood vessels could be observed. No appearance of preceding inflammation, and therefore pure degenerative atrophy of the ganglionic cells was suggested as erimary. With this view the hæmorrhagic diathesis was suggested, but during life the patient had no tendency in this direction. There was no trace of sclerosis in the lateral or pyramidal columns which are required by Charcot's view, nor were there to be observed any cerebral change. In cases where there is no stiffening Charcot and his school explain that the atrophy of the ganglia is first the cause and the lateral sclerosis follows which are not so in this case.

◆

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, April 13th.

Syphilis and Lichen.

Prof. Neumann showed several cases of syphilis and lichen to the Gesellschaft to confirm several remarks made on the localisation of the syphilitic virus. He pointed out that the skin and mucous membrane was the frequent site of gummata, papules and rashes, as for instance the tongue, periosteum, &c., and such gummata, are not excluded from the site of the primary affection. Here he produced a patient five or six years syphilitic, with post infection three and a half years ago, and a gumma on the last place of infection. Again, when no clinical symptoms are evident the histological examination will reveal undoubted changes with the presence of round cells on the walls of the blood vessels, at the exit from glands, and in the upper layer of the cutical tissue. He next showed the photos of cases from moist papules on the body which had been taken from patients attending hospital three years ago, and had also returned within the last few weeks with a repetition. Small parts had been excised from the skin at the efflorescent point and a similar condition observed in the upper layer. He also showed a patient, æt. 31, who, three years ago, had a sclerosis on the under lip; after twenty-five inunctions it disappeared; later a repetition on the left side of the thorax with rupial efflorescence brought him back to hospital. The sclerotic under lip again repeated itself, becoming elevated, hard, and sharply defined, centre white and margin brownish red. In a similar demonstration by excising a part four years after inception, the round cells can be found under the epithelium and cutis. He next brought forward a patient, æt. 38, with diffuse lichen ruber acuminatis and lichen planus. The rash was thicker on the trunk, light red in colour, covered with a hirsutous scurf, and about the size of hemp seed. Another lichen ruber acuminatis had it on the back of the hands and around the joints about the size of corn seed depressed in the centre. Another of lichen planus was shown on the surface of the tongue, the lips, and angles of the mouth, having intense bluish spots and streaks between which the epithelium was absent and speckled resembling syphilitic papules. This case was of considerable interest to the society as it demonstrated in the same individual both of the classic lichen, viz., lichen ruber exudativus of Hebra (Kaposi's ruber acuminatus) lichen ruber planus (Urlson).

The cases gave rise to a discussion on the diagnosis of pityriasis ruber pilaris, which Neumann said could be distinguished by the efflorescence, size, hardness, and scurf.

Hypertrophy and Regeneration of Liver.

Kretz read a paper on his investigations in this direction and said that the hypertrophy of the tissue was either local or general.

Macroscopically the augmentation might be divided into two great categories, while microscopically these divisions could be well defined. Macroscopically the cells were found either in large assemblages or pressed into the form of small islands.

Microscopically the increase is found either in the cell element or the cell itself, the hypertrophy proceeding in proportion with the hyperplasia. He classed the changes: (1) Where the elements increased regularly; (2) Where the volume of an individual part increased usually peripheral; (3) Where the hypertrophy assumes the form of cell vegetation producing new growth. A number of examples shown illustrated the paper, one where the acini alone caused the increase, typical of a wide class, arising from injurious causes as echinococcus, gumma, inflammation, &c., which destroy a part of the healthy organ, leaving the unaffected to increase by compensation that often surpasses the original size in volume.

Other preparations of biliary cirrhosis had irregular atrophy; some might be classed as acinous in origin, and finally healed by regeneration. This compensating function was an active factor. Clinical proof cannot be adduced to prove how far this can be followed in cirrhoses, but presumably it is not absent in this direction. He considered that this power continues till a very old age.

Pontfick here related a case of echinococcus, æt. 73, where regeneratioon took place.

◆

The Operating Theatres.

LONDON HOSPITAL.

Pelvic Pritonitis—Encysted Peritoneal Abscess.—**Mr. Treves** cut down on a swelling, said to be an ovarian tumour, in a woman, æt. 30. Mr. Treves remarked that the tumour did not strike him as ovarian: it was very tender, the patient's temperature was high, she had been ill for six weeks with great pain, but said she had only noticed the tumour during the last fortnight. No proper examination of the abdomen had been possible owing to the excessive pain, even when the patient was made to hold her breath. Mr. Treves said in all probability it was pelvic peritonitis, he drew attention to the malaise of fever experienced by the patient, also to the absence of any indications of inflamed ovarian tumour or of dermoid ovary. On examination under the anæsthetic he found an ill-defined lump mass with a sort of ill-defined fluctuation, curiously median, though leaning slightly to the left. He cut down carefully in the median line; on cutting through the peritoneum he came down on an encysted abcess cut off from the general peritoneal cavity, and containing a large amount of pus, which though stinking had not, he remarked, the characteristic smell of that containing the bacterium coli commune. This cavity he washed out with a large quantity of fluid, finding in the process a few smaller pockets of pus (a very ingenious tray being used under the patient's loins, being an ordinary metal tray traversed in its centre by several pieces of wood with smooth rounded edges, these were a little higher than the edges of the tray, on which latter the patient's pelvis rested; this tray was easily placed in position in the place of the middle cushion of the operating table, showing the advantages of the cushion portion of the table being divided into three parts). Into the small cavity left, the viscera having resumed their proper places after evacuation of the pus, some iodoform emulsion was injected.

ST. MARY'S HOSPITAL.

Excision of Tongue and of Submaxillary Glands.—Ligature of both Lingual Arteries.—Mr. G. Silcock operated on a man, æt. about 35, who had been in the hospital six months ago with a small patch on the tongue; this had been freely excised, a wide sweep being taken all round; at the time it was by no means certain what the growth was. However, at the present time the patient had come back with a recurrence, and it was decided to remove the whole tongue. As the growth was very far back, quite at the root, it was thought better to ligature both linguals. This was done in the usual way in a comparatively short time. Next a thread was passed through the centre of the tongue and the organ drawn well forward and rapidly snipped away with the scissors, the operator beginning at the frænum and taking away the whole tongue and the anterior pillars of the fauces. The bleeding was necessarily very slight, but a deep vessel which was thought to be the left ascending pharyngeal or one of its branches gave a little trouble; however, a pair of forcipressure forceps eventually secured the bleeding vessel, and these were left on at the end of the operation for safety; controlling the hæmorrhage was much facilitated by the floor of the mouth being pushed up on the left side through the wound made by tying the lingual artery on that side. The next proceeding was the removal of the submaxilliary glands; the one on the left side was hardened, and as a measure of prudence the one on the right side was also taken away. The removal of these glands gave rise to a lot of troublesome hæmorrhage, and materially prolonged the operation, as the arresting of the bleeding took some time and care. The wounds made for the ligature of the linguals served also for the excision of the glands. The opening on the left side extended through into the mouth during the operation, owing to the extensive removal of the base of the tongue on that side. Both wounds were lightly sewn up.

ST. THOMAS'S HOSPITAL.

Removal of Urethra and Portion of Bladder for Carcinoma.—Closure of Bladder Wound.—Establishment of Permanent Supra-pubic Opening.—Mr. Battle operated on a woman, æt. 46, who was the subject of extensive malignant disease of the urethra extending backwards to the bladder. The patient, who was a fairly well nourished woman, but who stated she was losing flesh, came to the hospital complaining of retention of urine; she said she had been unable to pass her urine without a catheter for the last fortnight, and that her doctor who had been passing the instrument for her had said that the retention was due to a growth. For three or four months before the retention she had suffered from incontinence, with pain on micturition, and said she had experienced more distress since the retention came on, that she prayed that something, no matter how severe, might be done to afford relief. She was in much mental distress and very excitable. Examination of the urethra showed the presence of a hard solid growth, extending from the orifice backwards to the bladder; the urethra was completely surrounded by this growth, which was fixed to the pubic arch. On passing a catheter no great pain was caused, there was no unusual roughness, nor was its use followed by bleeding; the only evidence of the breaking down of the tumour was at a point in the anterior wall of the vagina, a little to the right of the middle line, where the mucous membrane was adherent; no enlarged glands could be felt anywhere; the urine contained some albumen and muco-pus, and was slightly alkaline. The operation was performed under ether. Mr. Battle first performed supra-pubic cystotomy, and explored the vesical surface of the growth, closing the wound in the usual way excepting along a track occupied by a large rubber tube. Dressing was placed over this wound, and held in position by bandage. The patient was then placed in the lithotomy position, the labia were well retracted by assistants and the growth removed by means of knife, scissors, and raspatory. An incision was first made along the arch of the pubes from side to side beyond the limits of the growth, all the tissues under the pubes being separated from the bone as far as the neck of the bladder, the mucous membrane of the vagina being divided as required; the tumour was then cut off by scissors from behind forwards. It was found that anteriorly the disease extended further into the bladder, and this portion was removed from behind the pubes by means of scissors. The hæmorrhage was not great, and was easily controlled by means of artery forceps. The bladder was washed out with boracic solution, and the sub-pubic opening then closed by strong wire sutures; these were passed through the vaginal portion of the wound, which was then united to the soft parts in front of the pubes. The wires were left long. Iodoform was dusted into the vagina, and an iodoform plug inserted so as to bring the deeper portions of the wound into contact. Mr. Battle drew attention to the unusual character of the growth, which resembled scirrhus more than any other form of malignant disease. He stated that a long time ago he had suggested this method of operation for similar cases where the whole urethra had to be removed, because the condition of the patient with complete absence of control over the functions of the bladder was most miserable; the urine trickling away down the patient's thighs caused great discomfort to herself, whilst the constant offensive odour was not only hard for her to bear, but made her presence in a household almost intolerable. The question that he had considered seriously was whether it was advisable to make the supra-pubic opening at the time of the removal of the disease, or whether it was better to do it at a later stage when the wound had commenced to granulate; there was no doubt that it was easier to act as he had done, for the bladder could be well distended, the urethra being intact. The presence or absence of cystitis must, he thought, be taken into consideration, as the risk of spreading inflammation in the cellular tissue round the bladder had to be considered.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 18, 1894.

THE DENTAL FUNCTIONS OF THE GENERAL MEDICAL COUNCIL.

When we assert the proposition that the business of the Council should not be worked on trade-union principles, nor influenced by any body of interested persons, we expect that the statement will meet with general agreement. We feel it necessary to say that it appears to us that the General Medical Council has made and is making itself the servant of the British Dental Association by making and altering regulations to suit the views of that organisation. We found this statement upon the fact that the Council, acting upon the advice of the Education Committee, has recently revoked the recognition granted to foreign dental degrees which it had previously accorded, and has done so, on its own showing, for reasons outside and beyond the considerations of educational and examinational efficiency, which alone it is bound to regard. Under the Dentists' Act of 1878 (41 and 42 Vict., cap. 33) a colonial dentist (under section 8), or a foreign dentist (under sec. 7), is entitled to registration in a separate column in the Dentists' Register if he possesses—

> "Such certificate, diploma.................... &c., as may be recognised, for the time being, by the General Medical Council as entitling the holder thereof to practise dentistry or dental surgery in such possession or country, and as furnishing sufficient guarantees for the possession of the requisite knowledge and skill for the efficient practice of dentistry or dental surgery."

By virtue of this authority the General Medical Council registered from time to time a considerable number of persons holding the foreign diplomas of Doctor of Dental Medicine of Harvard University, and Doctor of Dental Surgery of Michigan University, thereby implying that the Council was satisfied that the possession of such diplomas was satisfactory proof of "the requisite knowledge and skill for the efficient practice of dentistry" (*see* "Minutes of Med. Council," vol. 16, pp. 148-198). The grounds upon which this recognition was granted by the Gen. Med. Council are stated in the Report of the Education Committee ("Minutes," vol. 30, Appendix 6, page 10), as follows :—

> "In each of these institutions the candidate is required to have devoted three years to professional study, and to have attended lectures and courses of instruction in a Dental College during two years. The examinations, which are written and practical, including operations actual and the preparation of specimens of mechanical dentistry, appear to furnish sufficient guarantees of the possession of the requisite knowledge and skill for the efficient practice of dentistry."

At this date no preliminary examination was required by Harvard, and the course of study there covered only three years, while that demanded for the British diplomas extended over four. Nevertheless, the General Medical Council deemed that the Harvard and Michigan dental degrees furnished "sufficient guarantees of the possession of the requisite knowledge and skill for the efficient practice of dentistry," and those degrees were accordingly admitted to registration in the column of the Dentists' Register set apart for colonial and foreign registration. By virtue of this recognition a considerable number of Harvard and Michigan dentists were admitted to the Register, but, after a while it was discovered that certain of them had been illegally so admitted, because, according to the Act, a British subject cannot be registered in respect of a foreign degree unless he has resided in the degree-granting country for at least ten years, though a foreign degree-holder of any other nationality may do so. For this reason, the names of foreign dentists who did not come under this proviso were struck out, and at the present date twenty-seven graduates of Harvard and Michigan appear in the Foreign Section of the Dental Register. Up to this point the question is clear. The General Medical Council put its official brand on these degrees as "furnishing sufficient guarantees of the possession of the requisite knowledge and skill." But the situation is now altered, inasmuch as the General Medical Council, at its meeting of May, 1894, suspended the registration of these degrees, and, in fact, closed the Foreign Section of the Dental Register against all comers, and practically abrogated its function of registering foreign dentists. The reasons for this extraordinary procceding will be found in the Report of the Education Committee (Appendix 7, p. 10, vol. 20 of Council Minutes for 1893). It appears that when the Baltimore College and others found that the Harvard and Michigan had been admitted to registration, they at once proceeded to level up their educational standard to that of the latter bodies, and, having done so, applied for similar registration. The Education Committee in its Report admits that these Colleges had "brought themselves up to the standard of Harvard and Michigan, and that their teaching appliances are satisfactory, and from personal observation the Committee have been assured of the excellence of the teaching arrangements in such centres as Baltimore and Philadelphia." What, under these circumstances, has the General Medical Council done? Not only did it refuse to accept the degrees of the bodies which had altered their curricula and examinations to meet the requirements of the Medical Council, but it surmounted the dilemma by actually withdrawing the recognition and registration which it had granted to Harvard and Michigan on the express ground that these degrees furnish "sufficient guarantees of the possession of the requisite knowledge and skill." The reason for this change of front is to be found in a Memorial of the British Dental Association printed at page 4, Appendix 7, of the Minutes of vol. 30. This Memorial is signed by seventeen members of the Association, and it asks the Medical Council to withdraw the right of registration from foreign dentists not on the ground of insufficient educational standard of the foreign colleges or in respect of professional education or examination, but because the preliminary examinations of these colleges are alleged to be insufficient, a statement which is disproved by the comparison set out in page 5 of the Minutes. However, it is manifest that any deficiency in this respect was fully condoned by the General Medical Council when it recognised the American degrees at a time when the preliminary standard was admittedly much lower. The real reason, however, for disfranchising the American Colleges is to be found at p. 11 (paragraph 3 of the Education Committee's Report, Appendix 7, p. 11), where the Committee express the opinion that "a greater injustice is done to the licentiates of the British bodies by placing them on the same level as the diplomates of the two American Colleges." In other words, the British Dental Association has found the professional competition of the American registered dentists to be inconvenient, and it has put pressure upon the General Medical Council of sufficient force to secure the disfranchisement of all foreign dentists and the abrogation of the powers of the Council in respect of foreign registration. We are very strongly of opinion that a very dangerous precedent for action by the Council is thus created, which, if we permitted it to remain unchallenged, might be used in other directions at a future time. We submit that if the British dentists did not like the prospect of professional competition with foreigners they should have opposed (or rather should have abstained from promoting) the sections of the Act which imposed upon the Medical Council the duty of registering all such foreign qualifications as might be found to be up to British standard. Since, however, the Medical Council *was* invested with such function, and exercised it deliberately in favour of Universities of the highest character, it seems to us to be an outrageous proceeding to turn back upon the Universities and expunge them from existence without any allegation that their educational standard had fallen off to such extent as to justify ostracism.

◆

HYPNOTISM.

Hypnotism, in spite of the untiring efforts of its friends and upholders, has hitherto failed to attain any real foothold in practical medicine. Nor can the scientific inquirers of to-day lose sight of the fact that it is the lineal descendant of such superstitions as magic, witchcraft, and astrology. Towards the end of the eighteenth century it assumed the guise of mesmerism, the system introduced into Paris so successfully by the Viennese quack Mesmer. In our own days mesmerism has been revived under the form of hypnotism, of which the latest and most pseudo-scientific application is hypnotic suggestion. The application of the latter method, indeed, is claimed by a certain limited number of professional enthusiasts to have a distinct therapeutic value in the relief of pain and of other morbid conditions. But notwithstanding the energy and the persistence with which these claims have been advanced, hypnotism has not thus far, as already stated, obtained any hold upon the medical profession, and we have yet to learn that it has materially lessened the demand for the services of orthodox physicians or anæsthetists. If, again, we turn to the testimony of the hypnotists, we find it of a vague and unsatisfactory nature. Take, for example, the extremely guarded evidence of Dr. Kingsbury, who is one of the most enthusiastic advocates of hypnotism. In a paper on the subject first read before a medical society and lately re-published in a lay journal, and presumably meant to carry conviction to all and sundry, he writes: "Personally, I have no hesitation in saying that, though I have induced hypnosis hundreds of times, I have never seen any injurious consequences—moral, intellectual, or physical—follow; on the contrary, I can conscientiously say that in most cases I have observed signs of improvement, even if only temporary. I do not mean that every case was successful in being followed by relief of the malady for which the aid of hypnotism was invoked—far from it; but in the very least successful cases, where no amelioration of the ailment ensued, there has been a feeling of composure and comfort. In other instances, equally unsatisfactory as far as the primary object of the hypnosis was concerned, there has followed a general improvement in health. In many cases hypnosis has been followed by a complete cessation of the pain or other affection for which help was desired." If ever a mission was "damn'd with faint praise" it has surely been done in the foregoing passage. Dr. Kingsbury introduces the subject of hypnotism in a formal treatise. First there is a flourish of historical trumpets and then a fierce attack, in which sarcasm, ridicule, and *petitio principii* struggle for the lead, upon all who have ventured to call the obscure dogmas of the "hypnotic process" into question. But when he arrives at the pith of the matter, namely, as to the curative powers of the system he advocates, all that he can "conscientiously" say is that in most cases he has observed "signs of improvement, even if only temporary." This, we venture to assert, is hardly the language of strong conviction, neither is it suggestive of the scientific doctrine that has resulted from many years of patient and candid investigation. It rather reminds us of the reasoning one associates with tracts of a religious nature intended for the young. "It seems to me," he writes, "a powerful incentive to the study of hypnotism that it is so old. Surely an agency which has been resorted to since the early days of Rome and Greece, and has never wholly disappeared, may have something useful in it. If we allowed this objection was valid, what would become of nearly every remedial drug or measure we now adopt? Massage, electricity, hydropathy, and antiseptics were probably all in vogue before the time of the Cæsars." Let us remind Dr Kingsbury that many agencies, such as thieving, midnight assassination and parricide, have never wholly disappeared since the early days of Rome and Greece, and may therefore be defended, according to his theory, on the mere ground of age. Again, does Dr. Kingsbury mean to assert that massage, electricity, hydropathy, and antiseptics, existed as we know them in the early days of Rome and Greece? If he means that the empirical use of some of the principles of these measures was known in the times he mentions, that is another and totally different thing. Electricity and antiseptics have undergone an enormous scientific developement and application, while massage and hydropathy have become more exact in their methods. The mere lapse of ages, however, does not appear to have yet raised the mystic science, of which hypnotism is the modern outcome, to any such scientific standard of realised ideals. The therapeutic claims of the system have been before the medical profession, according to Dr. Kingsbury, for a very long period, and it is certain they have not been hitherto adopted. It is surely fair to assume that this attitude is the result of a failure in hypnotism to establish its claims and not to prejudice on the part of the medical profession. Science, at any rate, has winnowed out the grain from the chaff in astrology, electricity, and alchemy; why then has it failed in the mystic and mysterious branch of psychology that has been so variously named at different stages of its existence? One great objection to hypnotism and its allies has always lain in the facility with which it lends itself to aid those who fasten on the weaknesses of mankind. No doubt the feeling of medical men generally is that hypnotism had better be left alone until some definite laws of action can be formally proved by its advocates, to whom, it must be remembered, the burden of proof must necessarily be left.

Notes on Current Topics.

Is the Association of Fellows of the Royal College of Surgeons of England a Radical Body?

AMATEUR politicians are always a consequential, if not an assertive, body of persons, especially when it appears to them that their own interests are involved. The truth of this observation was very aptly illustrated in a remark which fell from a speaker at a meeting last week, in which he described the members of the Association of Fellows as "Radicals"—radical, that is to say, as far as their policy in promoting reforms at the College of Surgeons, England, was concerned. But what did he mean by the term "Radical" used in this connection? That is a problem which we cannot pretend to make any attempt to solve. Nevertheless, as attention has thus been drawn to the subject, it may not be unprofitable to make some observations respecting it. In the first place, regarding the "Radicalism" of the Association of Fellows purely from the point of view of a Conservative in a political sense, the question might fairly be raised: Where is the evidence of that "radicalism" in the reforms which the Association has been instrumental in promoting? Has the Association advocated any wholesale "democratical" programme by which the well-being both of the College as well as of the corporate body would be endangered? Has it lent itself to the furthering of any object by which anything less than good could result from the Fellows and Members on the one hand, and the College itself on the other? If "Radicalism" in this connection means obtaining from the Council of the College concessions from which the whole body corporate, inclusive of the members of the Council, benefit, then the interpretation of the term must be regarded in a much more favourable light than that which is usually attributed to it in a political sense by those who are not Radicals. But in respect to College politics the terms "Conservative" and "Radical" are quite inapplicable. This arena of difference of opinion cannot be described by the use of such terms. If those representing the Council party are to be classed as "Conservatives," it is by no means the case that those who represent the forward movement can be regarded as "Radicals." As we have observed before, all that the Association has claimed and agitated for has been not only in the interests of the Fellows, but also in those of the Council itself. Was it a very radical measure to ask for a common room at the College, or to agitate for the issue of voting papers, both of which, in the first instance, came as suggestions from the Association? And yet each of these may be regarded as a very fair type of the so-called "Radicalism" which the Association has promoted. Obviously, therefore, those who apply the term "Radicals" to members of the Association display a gross ignorance of the subject, which stamps at once the amateurishness of their convictions.

Advertising Extraordinary.

IT has on various occasions been our privilege to congratulate our powerful contemporary the *Times* on the judicious supervision displayed in respect of the advertisements admitted to its columns. Even the *Times'* Argus, however, seems subject to fits of somnolence, witness the extraordinary advertisement which graced (?) that journal on one occasion, at least, in the course of last week. "Homocea"—whatever that may be—"touches the spot"! So begins the column. This vague assertion is particularised forthwith by the assertion that Homocea "touches the spot in piles," a very indelicate allusion, and one singularly ill-fitted to the columns of what the French call sarcastically *le journal le mieux informé du monde*. Various other spots are mentioned, some dermatological, others gynæcological, but a number of really startling certificates are subjoined emanating, *inter alia*, from the Earl of Carrick, H. M. Stanley, and others, whose motive for thus rushing into print must for ever remain a matter of conjecture. The noble Earl expresses his gratitude that in his case Homocea touched the piles, a naïve admission of an infirmity which most people with an ordinary dose of delicacy would hesitate to confide to an awe-stricken public. The enthusiastic Earl also certifies to the beneficent effect of the panacea in curing a boil and a scurvy leg. Mr. Stanley, not to be beaten in this game of brag by the noble Earl, certifies that the ointment proved sovereign in a fractured limb of his own, but he omits to mention whether or not it enabled him to dispense with the use of a splint. In any event, it looks as if Stanley had discarded the services of the late Dr. Parke, of whose professional ability, however, he on various occasions speaks with great fervour. Further on, a Lady Keane "has much pleasure" in recommending the unguent in the treatment of rheumatism, and—*horresco referens*—piles. Piles are evidently not the sole heritage of plebeians, since here are an earl and a "lady" who admit being subject thereto. A "lady" may perhaps publicly own to relief from neuralgia without impropriety, but it is new to see them rush into print with such admissions, and we positively tremble lest they, or some of them, should wander off into details of an even more unsavoury description. *Absit omen!*

Doctors in the Law Courts.

A number of cases disposed of in the various law courts during the past week have illustrated more than one of the pitfalls which beset the path of medical men. In one of them Dr. Griffiths, of Swansea, appeared as co-respondent in a divorce case. However, the charges against him broke down completely, and the case was stopped by the jury. In the course of the trial the unpleasant fact was disclosed that a Dr. Lewis, although he was made aware of the respondent's charges, nevertheless did nothing to sift the matter. Dr. Griffiths may be congratulated upon the complete vindication of his character, although at the same time it must be admitted he used somewhat incautious expressions in writing to the respondent. From documents produced in evidence the latter appears to have been a worthless and designing woman. A second case was an action brought by Dr. Logie against Dr. Maxwell, both of Woolwich. The plaintiff had formerly been under a bond not to practise in the district, but on the death of the principal considered himself free to settle in the neighbourhood, which he accordingly did. Later on he became a candidate for the Medical Officership to the Poor-law Board, whereupon Dr. Maxwell wrote to one of the Guardians stating that Dr. Logie had returned to Woolwich in spite of his promise to the contrary, and that he had tried to undersell the candidates in another local contest. These accusations constituted the alleged slanders, and were assessed by the jury at a farthing damages. Another case of an extraordinary nature was that of Dr. Cullingworth, one of the physicians to St. Thomas's Hospital, London. An action was brought against him by a nurse, on whom he had gratuitously performed an abdominal operation. The nurse's grievance was that she agreed to the removal of one ovary, whereas Dr. Cullingworth had actually removed both, and thereby deprived her of the power of procreation, she being at the time engaged to be married. She went to the doctor's house, which she refused to leave until removed by a policeman. The plaintiff, on the advice of her solicitors, had previously abandoned a suit brought on the ground of damages sustained from an unauthorised operation. The present action arose out of her visit to the doctor's house, and the subsequent intervention of the police. The jury threw out her suit, which claimed damages for assault and malicious prosecution, and expressed their opinion that Dr. Cullingworth was completely justified in all that he had done.

When are Inquests Unnecessary?

The coroner at Exeter has been taken to task for wasting the money of the ratepayers by holding inquests which appeared to be unnecessary. At an inquiry held by him respecting a case of sudden death the jury took upon themselves to express their opinions on this subject pretty freely. But the coroner at once placed the closure upon the discussion by informing them that upon such a matter he was the sole judge. We learn, however, from the *Western Morning News* that there is a strong feeling in Exeter that a very large percentage of inquests which the coroner holds might be dispensed with, and the fees saved to the ratepayers. "There is not a town," our contemporary adds, "in the kingdom in which inquests are so frequent, and yet the death-rate on the average is below that of the principal centres of population. If a child dies from convulsions—an almost everyday occurrence—a jury is summoned to consider the cause of death, although the medical man has had no difficulty nor hesitation in giving a certificate; and should an octogenian expire suddenly from old age an inquest would almost of a certainty be held. The question is naturally asked, why should this be necessary in the city when it is not required in the county?" This question of the holding of inquests is one which we are glad to see brought forward for discussion. The answer to the query raised by our contemporary is that the holding of inquests in country places is often a duty which is largely shirked. It frequently happens that upon the merest pretext a country coroner decides against holding a public inquiry into a case of sudden death, and it is not unusual, even when such inquiries are held, for no medical evidence to be submitted. This policy, whatever be the motive for its adoption, is an abuse of the coroner's prerogative, and is calculated in the end to be far more harmful to the ratepayers and the country generally than anything which might be held to be the result of over-zealousness on the part of a coroner.

The Birmingham Statistics of Small-Pox.

At a meeting of the West Bromwich Board of Guardians held last week a curious discussion arose in respect to the payment of an item charged in the accounts presented by the Finance Committee. A bill was handed in for £7 5s., which liability had been incurred for posting bills relating to small-pox. It appeared that the Board had previously agreed to issue "posters" with the view of stamping out the serious epidemic of small-pox in the union, and had given the clerk instructions to carry out this decision. Accordingly, the clerk applied to the Birmingham authorities for some figures, which showed that from January 1st, 1893, to January 31st, 1894, 1,203 cases of small-pox were admitted into their hospital. Of these ninty-six had died, and there was not a single case among them of a re-vaccinated person. Four per cent. of deaths were of patients vaccinated, while thirty-two per cent. were unvaccinated. These figures formed the basis of the "posters," "because," as the clerk said, "he thought the Board was serious in the matter and wanted its order carried out in the most effective way possible." The clerk was perfectly right; of what use could such an order be unless it was properly carried out? But certain members of the Board at the meeting last week described the "bill-posting" method as a scandalous thing, even if it was not illegal. One member further observed that the bills had been posted in such a manner at Wednesbury that they had "frightened the people into fits"! Again, a strong protest was made against such a large expenditure of money for the purpose, and it was pointed out that on two walls in a particular locality no less than seventeen "posters" had been placed. Despite, however, all this expression of displeasure expressed by some of the members of the Board, the report was adopted; the clerk's explanation was held to be satisfactory, and we consider that he did nothing more than his duty in the matter.

The Apostle of Anti-Adulteration.

WE briefly announced in our last the death, at the ripe age of 77, of Dr. Arthur Hill Hassall, the well-known analytical chemist. In him a very notable man has passed away; he may be said to have been the father of the anti-adulteration law of Great Britain, and the progenitor of all public analysts and other officers whose function it is to protect the public against adulteration frauds. When he had achieved distinction as an analyst he was taken in hand by the *Lancet*, and employed to conduct a special analytical commission into the purity of samples of commercial food and drugs. Both our contemporary and its representative, Dr. Hassall, covered themselves with glory by the honesty and determination with which they exposed the abominable system of fraud which was being perpetrated by the sophistication of almost every article of consumption. Hassall was pelted with abuse, and the *Lancet* overwhelmed with threats of actions by those who were making huge fortunes by this method of swindling, but, with remorseless determination, they kept "hammering away" until they succeeded in making the iron red hot and forcing the public to listen, and the Legislature to interfere for the protection of the consumer. It is no hyperbole for us to say that there is not a man, woman, or child in Great Britain who has not deep occasion to bless the name of Arthur Hill Hassall, and to honour the *Lancet*, which so nobly and unflinchingly supported him. It is not generally known that Hassall served his apprenticeship to Sir James Murray, of Dublin, the inventor of "Fluid Magnesia."

THE Pharmaceutical Conference will be held at Oxford on the 30th of July and following days.

The Report of the Sanitary Convention.

THE Report of the International Sanitary Convention, which was signed in Paris on the 2nd instant has just been issued, and consists of four parts. The first comprises the text of the police regulations for the transport of pilgrims, and the second section deals with the sanitary inspection of the pilgrimages of the Red Sea. After determining the sanitary regulations applicable to vessels conveying pilgrims coming from the south, the Convention requires that such ships shall proceed in the first instance to the Hedjaz, and put in at Samaran, where a sanitary station will be established. The third section points out the sanitary measures required in the Persian Gulf. The fourth and concluding division of the Convention consists of a certain number of suggestions as to the best means of ensuring the carrying out of the new regulations. Before separating the Sanitary Convention adopted three resolutions. The first was in regard to the effective supervision of the caravans of pilgrims going to Mecca and Medina overland. The second referred to the sanitary protection of the southern frontier of Persia. Finally, the representatives of the signatory Powers to the Dresden Sanitary Convention express the hope that in the imperative interests of the public health the Powers which have not signed the Convention of Venice and Dresden will adhere without delay to these international arrangements.

Doctors as Sandwich-Men.

A SPECIAL correspondent of a morning contemporary has lately published an interesting paper on London sandwich-men. He says that the ranks of this "last resort of despairing poverty" are recruited from all classes of society, including the medical profession. The manager of a yard is represented as saying:—"One of my two medical men has trudged off, but the other is somewhere about the place. Oh, yes, a well-qualified man—double qualification I think they call it. What brought him down? The usual thing—drink, and drink still keeps him down. I have induced doctors in the neighbourhood here to give him an assistantship; but, bless you, there is no depending on him. He goes off on the drink and forfeits every chance. If it weren't for the drink I'm afraid we'd sometimes go short of men to carry our boards. We've got to thank the publicans for an unlimited supply of this kind of labour." Of course the foregoing must be accepted *cum grano salis*, yet it is to be feared that the picture is far from impossible. In every profession a certain number of men are bound to give way and sink into the depths under the pressure of competition and of misfortune.

THE death is announced of Miss Jessie Flewith-Hatch, one of the resident medical officers at the North-Eastern Fever Hospital at Tottenham. She was only in her twenty-seventh year, and had graduated as recently as last year at the University of London, taking high honours in medicine, and the gold medal in obstetrics.

The Water Supply at Gibraltar.

The British authorities at Gibraltar have for some time been in negotiation with the Spanish Government for the concession of a supply of drinkable water from Spanish territory. But the "Superior Council of War" at Madrid has unanimously resolved to advise the Spanish Government to refuse the request of the British, on the grounds that any such concession would be contrary to the provisions of the Treaty of Utrecht, and would, in the event of war with England, constitute an advantage to the enemies of Spain. We do not happen to be particularly intimate with the various clauses of the Treaty of Utrecht, and we are therefore not competent to offer a judgment in respect to this objection. On the other hand, it is difficult to believe that any person of ordinary common sense could see the reasonableness, even on grounds of international expediency, of the difficulty raised against the request on account of the contingency of the outbreak of war between this nation and Spain. As the water supply would take its origin in Spanish territory, surely the Spanish War Office could take measures to destroy the works whenever they felt so disposed. But however this may be, the decree has gone forth that residents at the "Rock" will have to look elsewhere than to the Spanish territory for their supply of drinking water. Clearly, in the dilemna in which they are placed, they want somebody to fill the office of the Hebrew prophet of old, who on one occasion merely struck a rock with his stick, "when the water flowed." There is plenty of "rock" at Gibraltar, but there does not appear to be much water, consequently some difficulty might be experienced in securing a person to undertake the duties in question.

A New Phase in the Prosecutions under the Pharmacy Act.

The "worm" has turned at last, and has now commenced a process of retaliation. In other words, the salutary prosecutions organised by the Pharmaceutical Society against the vendors of patent medicines containing scheduled poisons have excited the spirit of revenge among the producers of the nostrums. A Patent Medicine Defence Association has sprung into existence, which does not mean to allow chemists to have it all their own way. Last week this new organisation prosecuted several well-known chemists in Leeds for technical infringements of the 17th Section of the Pharmacy Act, and similar prosecutions have taken place elsewhere. Fines have been inflicted as the result of the actions, so that it may be conceded that the patent medicine defenders have been successful. Upon the whole the situation is somewhat a funny one. We have on the one hand the unauthorised sellers of poisons being prosecuted for infringing the Pharmacy Act, and on the other we have the prosecuted persons turning the tables by taking action against the legal dispensers of poisons for failing to carry out the details of the Act. Competition is always useful; the public will gain much from its presence in this particular instance.

Good Enough for Doctors!

The sad death of Surgeon-Captain Lindesay Carte, at Allahabad, on the 2nd instant, has deprived the Army Medical Service of a most popular, promising, and efficient officer, and it is only true to say that his untimely decease was largely due to the cruel adherence to departmental regulations which in his case might easily have been relaxed. Under existing regulations the term of service in India for Army Medical Officers is six years; of this period Dr. Carte had served five, and in consequence of ill health was invalided home for six months. At the end of that time he was compelled to return to India, only half convalescent, inasmuch as he would not be entitled to an extension of leave because he had not yet served six years by a few months. As was feared by himself and his friends, his half-regained health broke down when he reached India, and he speedily succumbed to fever. This is the sort of treatment which the War Secretary and "my military advisers" consider quite "good enough for doctors." It may be added that the deceased officer served in Egypt in 1886-7, and, when returning home, very nearly lost his life, and actually lost his health by the wreck of the *Tasmanian* in the Straits of Ajaccio. The captain and many of the crew died of exposure but he escaped with rheumatic fever. Before he had time to make a proper recovery he had to return to India, where—and in Burmah—he served until 1892. By way of variety he was called upon to combat the cholera epidemic at Rawul Pindee, where many of his Army medical brethren died. Medical officers in India are too frequently called upon to perform excessive tasks, and it is contrary to the interests of the Army Medical Service that these should be imposed upon hard and fast departmental lines. Surgeon-Captain Lindesay Carte was the third son of Dr. Carte, J.P., Medical Officer to the Royal Hospital, Kilmainham, and Headquarters' Staff in Ireland—an officer who has forty years' Army service, and the deceased's brother is Surgeon-Major of the 2nd Battalion Grenadier Guards. Dr. Carte was beloved by all who knew him, and to his many friends it will be a matter of profound and lasting regret that so promising and noble a career has been so suddenly and sadly brought to an end.

Red Tape in the Midlands.

A glaring case of official inhumanity was revealed last week at an inquest in Coventry. A child suffering from measles got severely burnt by accident. Her mother, acting on medical advice, took the little one to a hospital, where she was refused on the ground that "infectious" cases were not admitted. She then drove off to the Infectious Hospital, but the matron would not admit the child without an order from the medical officer. The latter official was telephoned to, but was not to be found. The distracted mother next vainly endeavoured to find her own medical man, and finally took the child home, where, one is not surprised to hear, the unfortunate little patient died next day. This case reminds us of several almost identical instances that have occurred elsewhere, and which have been commented upon in these columns. Surely it is time that the Local Government Board interfered to relax the stringency of the rules of admission to infectious hospitals. After all, the sanction of the medical officer is nothing more than formal, that is to say, if the patient be suffering from infectious sickness and be unable to pay for proper treatment. The driving about of dying patients from pillar to post is not likely to advance the cause of sanitary progress in the popular estimation.

A Centenary Festival of a Provincial Medical Society.

IT is just one hundred years ago since the Plymouth Medical Society was founded, and fittingly enough the members celebrated its centenary by meeting on the 11th inst. for the purpose of taking part in a festival dinner. Since its foundation the Society has flourished and maintained its position in a manner highly creditable to those of its members who have borne the burden of office. Among the early, or we believe original, office-bearers, were Drs. Remmett, Fuge, and Cookworthy, and the present President is Dr. Russell Rendle, who occupied the chair at the dinner in question. In the course of a speech in which the toast of "The Society" was proposed, the Treasurer, Dr. J. Elliot-Square, gave an interesting history of the Society, which added not a little to the attractiveness of the proceedings. About fifty members and guests were present.

Post-Graduate Course by the Staff of the Metropolitan Hospital.

A COURSE of twelve lectures with demonstrations, a notice of which appears in our advertisement columns, has been arranged by the staff of the Metropolitan Hospital, Kingsland Road, N.E. The lectures will be given on Wednesday afternoons during May, June, and July, at 5 o'clock, at the hospital. The course will be especially convenient for those medical men in the neighbourhood desirous of keeping abreast with the latest advances in the science and art of their profession. Moreover, as each lecture will be illustrated, as fully as possible, with cases, specimens and lantern demonstrations, it may thus be concluded that every effort will be made to add to the attractiveness of the course. Mr. Stephen Paget, 57 Wimpole Street, Cavendish Square, W., is the Honorary Secretary, to whom all inquiries should be addressed.

Retirement of Surgeon-General Collis, P.M.O. for Ireland.

ON Saturday evening the officers of the Army Medical Staff serving in Ireland signalised the departure from amongst them of their chief by a valedictory banquet, which was numerously attended, not only by the members of the staff, but by the chiefs of the Head-Quarter Department. Civilian guests were also invited to do honour to the occasion, and amongst those present were: Sir George Porter, Mr. Thornley Stoker, Vice-President of the College of Surgeons; Dr. Walter Smith, President of the Royal College of Physicians; Dr. Kidd, President of the Royal Academy of Medicine; Dr. Jacob, Dr. Heuston, Dr. S. Mason, and Dr. A. V. Macan. In response to the toast of his health, Surgeon-Maj.-Gen. Collis delivered a very interesting address, in which was embodied the result of his mature experience, and his observations were received with much cordiality. The incoming P.M.O., Surgeon-General Colohan, brother of Dr. Colohan, of Galway, was unable to be present, as he had not yet arrived in Ireland.

THE lectures which have been announced to be delivered on Electricity and its Therapeutic Applications, at the Richmond Hospital, Dublin, by Mr. Woods, throat surgeon to the hospital, will take place on Mondays and Fridays, not Wednesdays and Saturdays as previously arranged. The first lecture will be on Friday next, the 20th, at 4.30 p.m.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

SMALL-POX IN EDINBURGH.

THE small-pox epidemic which has existed in Leith for several months appears at length to have invaded Edinburgh in earnest, eighteen cases of the disease having been notified within the last fortnight. A very awkward case occurred in the Royal Infirmary last week, principally worthy of notice because of the Lord Provost's (Dr. Russell) remarks about notification. A patient from Leith applied at the skin clinique for advice. On it being discovered that he was suffering from small-pox the doctor in charge gave him a line to go straight to the small-pox hospital in Leith. This the man failed to do, but wandered about the streets for some hours, ultimately sleeping in a common lodging-house in Leith. It is very extraordinary, but it appears that there is no room in the Infirmary in which a case like this can be kept until the fever hospital conveyance is sent for him, though why he should not have been placed in the observation ward for a few hours is not clear. In the discussson which took place about this case at the Managers' Board the Lord Provost did not seem to see the harm of turning such a patient away, and was disposed to lay all the blame on Leith for not adopting the Notification Act, as if in this case, in which a doctor had not been consulted before, that would have been of the slightest use!

STUDENTS' HALLS IN EDINBURGH.—Of late years efforts have been made in Edinburgh as elsewhere, to introduce in some degree the college system for boarding students as it exists in Oxford or Cambridge, and no one has taken a greater interest or gone about the work with more successful or more optimistic energy than Professor Patrick Geddes. From time to time rooms have been opened in the old town in which colonies of students live together, at a cost certainly a little above that of the ordinary lodgings, but free from the uncertainties of landladies or the wiles of the landladies' daughters. In some of these colonies the arrangements for food, &c., are in the hands of the members themselves, one of their number being appointed caterer and treasurer for the time being. The latest development, though probably not the last, of this system is a large ornate building more in the warmer English style than the usual cold grey of the Scottish metropolis, which has been erected on the Castle Hill on the site of and incorporated with Allan Ramsay's old house. Ramsay Lodge, as it is called, will accommodate two classes of residents. In one half there will be accommodation for thirty students, while the other part is arranged for eighteen family residences to be filled up by University men or others interested in the scheme, and who will be expected, we suppose, to live together in brotherly love and felicity. The ceremonials in connection with the opening of the Ramsay Lodge branch of the

University Hall scheme took place last Friday, and were taken part in by the Lord Provost and a number of influential citizens. As the students in Edinburgh number somewhere about 4,000, many extensions of the scheme will be required to be of much service.

The Spring Graduation Ceremony of the Edinburgh University was held last week, but except for the honorary degrees already mentioned in this column, only one or two medicals were capped.

Glasgow University.—The Graduation Ceremony marking the close of the winter session at Glasgow University took place on the 13th inst. Among the recipients of honorary degrees was Professor Edward Caird. The new Master of Balliol was afterwards presented in the name of the students with an illuminated address, and in reply said, if the words of the address were too strong, he thought he might venture to say they expressed the ideal at which he had aimed. The medals and prizes were thereafter distributed by the Principal. A unique incident occurred in the presentation of a gold medal for an essay on "The Relations between Poetry and Philosophy" to Miss Catherine V. Bannatyne, Queen Margaret College (the competition was open to all the students of the University). Miss Bannatyne was gallantly and loudly cheered by the students. The Principal, after expressing regret at the absence through sudden indisposition of Lord Stair, the Chancellor, detailed the bequests which had been made during the year to the University, and referred to the death of Professor Leishman, and the departure from the University of Professor Edward Caird. Remarking that "intimate relationship was sometimes, at least, a hindrance to biographical impartiality," he spoke of the latter as possessing something of that nameless indefinable, yet invaluable power which pertains to the personality of a good teacher, and in having managed to secure for himself that which was more and better even than intellectual deference, a place in the affections and moral influence over the lives of successive generations of students. The Principal then delivered an address on "The Personal Elements in Teaching and the Advantages of a University Education," concluding with words of advice to the students who were entering on a new life.

Legacy of £10,000 to Paisley Infirmary.—By the death of Mr. John Clark, thread manufacturer, the Paisley Infirmary has benefited in the handsome bequest of £10,000.

Queen Margaret College, Glasgow.—In addition to various other handsome gifts to the University of Glasgow, the Bellahouston Trustees have intimated the following; a capital grant of £5,000 towards the erection and equipment of buildings at Queen Margaret College for the medical and scientific instruction of the students attending there, provided the University Court is willing to undertake the pecuniary responsibility of erecting the buildings in question.

◆

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (April 16th) was the last clinical evening of the session. Mr. Keetley showed two lads to illustrate his method of fixing the retained testis to the thigh by making a skin wound in the scrotum and neighbouring thigh, to which the testis after being drawn down, was sutured, by sutures passing through the fibrous tissue attached to the testis and piercing the tunica vaginalis. In one case the testis was left fixed to the thigh for five months, and then separated.

Mr. Swinford Edwards pointed out that the testicle in the older patient was atrophied, and asked whether this was likely to be recovered from. If not, he asked whether it would not have been an advantage to remove it.

Sir William Dalby (President) remarked that according to the lad the testicle had grown since the operation, and he suggested that in order to settle the question the lads should be shown again after a year or two.

Mr. Keetley declared his disinclination to inflict unnecessary mutilation, urging that even if useless, most persons would prefer to preserve the testicle. Moreover, there was positive evidence to show that atrophied retained testicles were not necessarily functionless.

Mr. Goodsall showed a woman, æt. 27, on whom, after performing colotomy for intestinal obstruction, he had made three ineffectual attempts to close the col[illegible] wound. He then opened the abdomen to asce[illegible] cause of the obstruction, and found an om[illegible] band loosely pressing upon the lower part of the sigmoid flexure. On removing this the vomiting following the anæsthetic, which had previously prevented the closure of the wound, did not occur, and a fourth attempt was crowned by success.

Mr. Hurry Fenwick showed a man on whom he had performed a modification of the Thiersch-Gould operation, removing the testicles, scrotum and penis right down to the perinæum on account of extensive epithelioma.

Mr. Fenwick also showed an instrument of the nature of a straight cystoscope, but which combined a sound and a cannula through which the bladder could be explored or drained *vid* a suprapubic puncture, in patients in whom the presence of an enlarged prostate prevented recourse to the ordinary cystoscope.

Dr. Lewis Jones showed a young married woman, æt. 19, with paralysis of the sterno-mastoid and trapezius muscles on the right side together with facial paralysis on the same side. He was unable to give any definite history of its origin or onset, but pointed out that it was unusual to see paralysis of the 7th cranial nerve associated with paralysis of the spinal accessory.

Dr. Beevor thought the symptoms were probably due to pressure on the facial and auditory nerves, and, lower down, on the spinal accessory. He commented on the fact that, though the spinal accessory was affected the accessory to the vagus had escaped, as shown by the fact that the soft palate was not affected. It was also, he said, somewhat remarkable that the hypoglossal should have escaped.

Dr Guthrie showed a woman, æt. 62, suffering from osteitis deformans, which she dated from an injury to the thigh twelve years previously.

WHAT CONSTITUTES UNSOUNDNESS OF MIND?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—We are sure Mr. Jessett need not apprehend any disagreement with his contention "that women passing through the climacteric are, in the first instance, never insane." We observe that he admits that the term "climacteric mania" is certainly misleading, and it is now clear that he does not by it connote alienation, but merely the prodromata of insanity. This being so, it is perhaps a little unfortunate that he takes for the text of his discourse a case in which the patient committed suicide. Now, in his first letter, Mr. Jessett stated that "many women thus suffering" (*i.e.*, from climacteric mania) "are certified as insane and placed in asylums." Therefore we elicit from him the somewhat startling opinion that there are in asylums many persons not insane.

Assuming the case of a person whose whole nervous system is in disorder, and most susceptible to develope unhealthy tendencies, a case that is fraught with potentialities of insanity: the question is as to the best treatment to adopt. We emphatically protest against any plan which tends to favour dilettantism in the treatment of such cases. If the patient can be kept under frequent *skilled* supervision outside an institution, by all means let this be tried; but if there is not *speedy* amelioration, the patient's chance of recovery should not be jeopardised through the false shame and ignorant fears still—despite our latter-day enlightenment—engendered by the very thought of that pretentious bugbear the asylum. Those acquainted with the modern asylum know well the pains taken to provide patients with the "bright surroundings, cheerful companions, and bodily and mental amusements so justly esteemed by Mr. Jessett.

We would here state our opinion that the system of "single care" is open to great abuse, and should be carefully safeguarded. We believe that *certifiable* cases are frequently placed with medical men whose acquaintance with insanity is extremely limited, and whose sense of responsibility must of necessity be less than that of the asylum physician, since in the former instance there is no official supervision. We have no direct cognisance of cases in point, and if, as we believe, the practice in question is widespread, the risk to recovery—and to life itself—is obvious.

Mr. Jessett clings to his view that asylums are manufactories for the production of lunacy. In opposition to it we would point to the case of voluntary boarders in asylums, of those patients admitted in alcoholic delirium, who shortly recover, of others (*e.g.* certain patients with epilepsy, or with recurrent mania) who, between bouts of excitement, are sane. All these present "aberration of mind," and yet do not "become insane from contact with insane people." How is it, we ask, if there is real danger of "contact insanity," that it is not pointed out by teachers, by text-books, and by the current organs of psychiatry?

We are, Sir, yours, &c.,

E. GOODALL and M. CRAIG.

West Riding Asylum,
Wakefield.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—Mr. Jessett, in his letter, replying to Drs. Goodall and Craig, asking him to define "climacteric mania," suggests that "mania, as applied to this disease, is certainly misleading, a more correct meaning would be conveyed by the expression mental disorder connected with the climacteric." To my mind, it is perfectly obvious that any given indefinite mental condition remains essentially the same, whether it be called "climacteric mania," or "mental disorder connected with the climacteric," but let us suppose, to suit Mr. Jessett's argument, the former be changed into the latter, I venture to assert that a person committing any illegal offence would be held irresponsible for such act, it being proved in evidence that the person was suffering from "mental disorder, connected with the climacteric." There could, therefore, be no good effected by this change of nomenclature.

On the other hand, the change might be productive of inestimable mischief, because it is evident that if a person was placed under legal restraint, under the term climacteric mania, and having gained liberty, thought proper to bring an action against the medical men certifying, all those holding Mr. Jessett's views, would prejudice any jury by giving evidence to the effect, which they must consistently give, that after all said, "climacteric mania" was a misapplied term; that it only implied "mental disorder connected with the climacteric." The counsel for the plaintiff would, of course, attempt to show that every female mind was more or less in a state of "mental disorder," and if the patient had happened to have made a complete and fairly rapid recovery, the medical man certifying would very probably be fleeced in heavy damages.

Yours very truly,

ONE MUCH INTERESTED.

◆

LIBEL ON A PHYSICIAN.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

SIR,—In December, 1885, the wife of Mr. Christie Murray, the novelist, placed *herself*—as all my patients do—voluntarily under my treatment, and for seven months resided in my family circle. The general cheerfulness of her companions seemed uncongenial to her mood, so after about seven months' residence she left "Dunmurry." From my house she went to Antwerp to live with a family of whom I knew naught beyond the fact that one member of it, a young artist, had been kindly treated, when ill in London, by the Murrays.

I heard nothing more about my patient from that time till last Wednesday, when I saw in the *Standard* that Mrs. Christie Murray had summoned her husband for maintenance, and that he, in justification apparently for his treatment of his wife, had sworn that "Dr. Stewart advised him to keep her 'at the end of a piece of string,' and send her to a place where she would have the opportunity of drinking."

There was not the slightest foundation for either statement. If either had been true, I would have deserved the condemnation of all right-thinking men.

To-day, therefore, I appeared before Mr. Vaughan, and obtained the permission of that magistrate to give an unqualified denial in the witness-box to the calumnious falsehood.

Mr. Murray thereupon made the *amende honorable* in open court.

My medical brethren know that since I commenced the special work to which I have devoted myself for 17 years I have maintained the doctrine that inebriety is a *physical* disease, and that its victims are objects of sympathy, to be treated medically and kept from risks while new brain tissue is being formed.

I ask you to allow me through your columns to assure my professional friends that I have never, by word or deed, departed from this position.

I am, Sir, yours, &c.,

JAMES STEWART, B.A., F.R.C.P.ED., L.R.C.S.I.,
formerly Surgeon R.N.

"Dunmurry," near Clifton, Gloucester.
April 10th, 1894.

Medical News.

The Middlesex Hospital.

THE authorities of this hospital were fortunate in securing the services of H.R.H. the Prince of Wales as Chairman at the festival dinner last week. In making an earnest appeal for funds he read a telegram from the Queen, in which her Majesty expressed a hope that the hospital might continue to be prosperous. His Royal Highness remarked that the occasion was special because of the necessity there was to erect other buildings for cancer patients. These would cost £12,000, and he might mention there were only twenty-six female cancer beds, and there were over 200 applications. Before the close of the evening it was stated that H.R.H. would contribute a hundred guineas to the fund, and that over £5,000 had been already collected.

Dr. Mueller's Snake-Poison Antidote.

A CORRESPONDENT sends us the following information taken from the *Evening Standard* of Melbourne, dated Feb. 15th last, which will be read with interest: "A case of snake-bite is reported from the Murrumbidgee. A rabbit-trapper placed his hand in a burrow, when he was bitten by a tiger snake 4 ft. 6 in. long. The reptile hung on his finger, tearing away the flesh before withdrawing his fangs. One of the man's mates tied a ligature round the wound, and sucked and cauterised it. The sufferer was taken to the neighbouring police barracks, where he was treated with Dr Mueller's snake-poison antidote. Though the case was unquestionably a bad one, and the snake was particularly venomous, the sufferer quickly recovered under the treatment."

Lanolin in Court.

SOME few weeks since the proprietors of "Lanolin," Messrs. Bruno, Jaffé, & Darmstaedter, sued Messrs. John Richardson & Co., drug manufacturers, of Leicester, for an infringement of their article, which the latter put on the market as "Anaspaline." In this action the German manufacturers were successful, whereupon Messrs. Richardson lodged an appeal in the Supreme Court of Judicature, and this came on for hearing last week before Lords Justices Lindley, Lopes, and Kay, who upheld the previous decision and dismissed the appeal with costs.

The Mortality of Foreign Cities.

THE annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta 30, Bombay 32, Madras —, Paris 25, Brussels 20, Amsterdam 15, Rotterdam 26, The Hague 13, Copenhagen 19, Stockholm 20, Christiania 26, St. Petersburg —, Moscow 32, Berlin 17, Hamburg 18, Dresden 21, Breslau 19, Munich 26, Vienna 26, Prague 29, Buda-Pesth 25, Trieste 32, Rome —, Turin —, Venice 21, Cairo 50, Alexandria 45, New York 21, Brooklyn 18, Philadelphia 19, New Orleans —.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Reading Cases.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of The Medical Press and Circular, may now be had at either office of this Journal, price, 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

Original Articles or **Letters** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

Mr. Timothy Holmes' letter on "The New Society of Fellows" is unavoidably crowded out at press.

THE INTERNATIONAL MEDICAL CONGRESS AT ROME.

To the Editor of The Medical Press and Circular.

Sir,—I have been kindly but erroneously given the credit for success of the Anglo-American Reception to English and American members of the Congress. The credit is due to the arrangements of a committee, of which Mr. and Mrs. R. Fowler MacKenzie, of Rome, well-known in medical circles, were the chiefs.

I am, Sir, yours, &c.,
S. M. Burroughs.

Royal Hotel, Naples, April 11th.

M.R.C.P.—The matter is more one for the Council of the Pharmaceutical Society than for the General Medical Council. Our correspondent had best communicate direct with the former authority.

THE MEDICAL DEFENCE UNION.

To the Editor of The Medical Press and Circular.

Sir,—Will you allow me through your columns to request members or would-be members of the Medical Defence Union to direct any communications relating to the Union to me at 64 Longridge Road, S.W., for the present.

I am, Sir, yours, &c.,
Alf. Bateman, Hon. Sec.

Mrs. Cust.—Our correspondent will see that we have discussed the matter in another column.

WHERE THE DEAD HORSES GO.

At a meeting of the Glasgow Town Council last week a question was asked by one of the bailies if the statement in the Sanitary Inspector's report that 48 horses were slaughtered for human food during the fortnight at the knackery at Glenpark was correct. Another bailie replied, quite correct. First bailie: for human food? Second bailie: yes. First bailie: they are not sold in the city? Second bailie: they are not sold in the kingdom. Another member of the Council expressed the opinion that it would be better that as a guarantee it should be always reported to be "for foreign consumption."

THE NUDE IN ART.

The Glasgow magistrates have held two meetings at which the picture of the "Slave Market in Cairo" was under discussion for the second time. At a previous meeting it was decided by three votes to two that the picture was of an indecent character and should not be allowed to be exhibited. The Chief Constable reported the facts of the magistrates having refused a licence, and of the exhibition having notwithstanding been opened. After a heated discussion the Chief Constable was instructed to report the case to the Procurator-Fiscal with the view of having a prosecution instituted against the manager of the exhibition.

Meetings of Societies, Lectures, &c.

Wednesday, April 18th.

Epidemiological Society of London (11 Chandos Street, Cavendish Square).—At 8 p.m., Dr. Caiger: On the Associated Incidence of Different Infectious Diseases in the Same Subject.

Royal Meteorological Society (25 Great George Street, Westminster).—At 8 p.m., The President (Mr Richard Inwards): Some Phenomena of the Upper Air (illustrated by lantern slides).

Royal Microscopical Society (20 Hanover Sq., W.).—At 8 p.m., Dr. A. M. Edwards: On an Eocene Deposit of Diatomacea—Origin of a Fossil Lake in New Jersey, and the Identification of it by the Diatoms found in the Deposits.

Thursday, April 19th.

Harveian Society.—At 8.30 p.m., Dr. James Taylor: Lantern Demonstration on Points of Clinical Interest in Nervous Diseases.

Neurological Society of London (National Hospital for the Paralysed and Epileptic, Queen Sq., W.C.).—At 8.30 p.m., Dr. Sharkey: A case of Cerebral Tumour.—Dr. Colman: (1) Dry Museum Specimens of Brain, by Whitwell's Carbolic Method; (2) Three Specimens of Tumours involving the Floor of the Fourth Ventricle.—Dr. Risien Russell: Defective Development of the Central Nervous System in a Cat (with lantern demonstration).—Dr. Turner: Tumour of Corpora Quadrigemina.—Dr. Tooth: The Peripheral Nerves in Alcoholic Neuritis.

Saturday, April 21st.

Royal Institution.—At 3 p.m., Mr. H. D. Traill: Literature and Journalism.

Vacancies.

Balrothery Union—Swords Dispensary District.—Medical Officer Salary £125 per annum, and £20 16s. 8d. per annum as Medical Officer of Health, with fees. Election 1st May.

Galway Union.—Medical Officer for the Turloughmore Dispensary District. Salary £130 as Medical, and £15 as Health Officer, with the usual extra fees. Applications to the Hon. Sec. before 30th inst. (See advert.)

Manchester Royal Infirmary.—Monsall Fever Hospital.—Assistant Medical Officer (unmarried).—Salary £100 per annum, with board and residence. Applications and testimonials to the Chairman of the Board by 21st April.

Newcastle-on-Tyne Dispensary.—Resident Medical Officer. Salary £250 per annum, with furnished residence. Applications and testimonials to the Hon. Secretary on or before April 20th.

North-West London Hospital, Kentish Town Road.—Resident Medical Officer and Assistant Resident Medical Officer. A salary of £50 attaches to the senior post. Candidates should attend a meeting of the Medical Committee on 1st May, at 5 p.m.

Royal College of Surgeons, England.—Examinership. Applicants must be Fellows of the College. Full particulars of the Secretary. (See advert.)

Wirral Children's Hospital, Woodchurch Road, Birkenhead.—Resident House Surgeon. Salary £50 per annum, with board, lodging on the premises, and washing. Applications and testimonials to the Hon. Secretary on or before April 24th.

Appointments

Hall, W. T., M.B., M.S.Edin., a Resident Physician to the Edinburgh Royal Infirmary.

Inkster, R. W., M.D., C.M.Edin., a Resident Physician to the Edinburgh Royal Infirmary.

Jackman, T. S. H., L.R.C.P.Lond., M.R.C.S., Medical Officer, *pro tem.*, for the Parish of St. Mary, Stoke Newington.

Leatham, R. R., M.B., B.Ch.Irel., Junior House Surgeon to the Bolton Infirmary.

Leigh, A., L.R.C.P.Lond., M.R.C.S.Eng., House Surgeon to the Bootle Borough Hospital.

Paget, C. E., L.R.C.P.Lond., M.R.C.S., D.P.H., Lecturer in Practical Hygiene to the Owens College, Manchester.

Ransome, A., M.D.Cantab., M.R.C.S., Professor of Public Health to the Owens College, Manchester.

Rutherford, A., M.B., M.S.Edin., Dispensary Surgeon to the Bradford Infirmary.

Sandeman, M., M.B., C.M.Edin., a Resident Physician to the Edinburgh Royal Infirmary.

Shiach, S. A., M.B., C.M.Edin., a Junior House Surgeon to the Bradford Infirmary.

Terry, J., M.R.C.S.Eng., L.R.C.P.Lond., Resident House Surgeon to the Royal Surrey County Hospital, Guildford.

Trevelyan, E. F., B.Sc.Lond., M.D., M.R.C.P., M.R.C.S., Assistant Physician to the Leeds General Infirmary.

Walker, A., M.B., C.M.Edin., a Resident Physician to the Edinburgh Royal Infirmary.

Way, W., M.R.C.S.Eng., L.R.C.P.Lond., Junior House Surgeon to the Clayton Hospital, Wakefield.

Whitehouse, E. St. J., L.R.C.P.Lond., M.R.C.S., Resident Medical Officer to the Children's Hospital, Birmingham.

Births.

Chawner.—April 12th, at Clay Cross, the wife of Alfred Chawner. L.R.C.P., M.R.C.S., of a son.

Macnamara.—April 10th, at Sarsfield's House, Kilmallock, the wife of P. J. Macnamara, M.D., F.R.C.S.I., of a son.

Marriages.

Roe—Peacock.—April 10th, at the Parish Church, Nunney, Montagu Walter Roe, M.R.C.S., L.R.C.P., of Constantine, Cornwall, to Lucy Williams Peacock, daughter of the Rev. Edward Peacock, of Rockfield House, Somerset, and of Martin, Wilts.

Shanley—Perry.—April 11th, at St. Austen's Church, Stafford, Michael Shanley, M.D., of Athlone, to Gertrude Agnes, daughter of Mr. John Perry, of Stafford.

Yeoman—Buckley.—April 11th, at Prestwich Parish Church, Stanley Yeoman, M.B., of Osmotherley, Yorkshire, to Florence, eldest daughter of James Buckley, of Prestwich Clough.

Deaths.

Clarke.—April 8th, at 18 Great Mersey Street, Liverpool, after a long and painful illness, John S. Clarke, M.R.C.S., L.R.C.P., Senior Surgeon to the North Division of the Liverpool Police, aged 48.

Hazard.—April 5th, at Sheffield, Joseph Hazard, M.R.C.S., aged 70.

Kelly.—March 27th, at Mazenod Avenue, Kilburn, George Patrick Kelly, M.D., F.R.C.S.I., aged 51.

Mumford.—April 11th, at Eyston Hall, Sudbury, Suffolk, W. L. Mumford, M.D., of Suffolk Street, Pall Mall, London, aged 53.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

The Medical Press and Circular.

Original Communications.

ON THE
USE OF THE COMMON RAGWORT
IN THE TREATMENT OF
DISORDERS OF MENSTRUATION.

By WILLIAM MURRELL, M.D., F.R.C.P.Lond.,
Physician to, and Lecturer on Pharmacology and Therapeutics at, the Westminster Hospital.

SOME years ago whilst staying in the country I learnt that the common ragwort was extensively collected by the old women of the place. I was anxious to learn for what purpose it was employed but could obtain no definite information. I was told, however, that it was made into tea and used as a medicinal agent. On inquiry I found that the use of the ragwort by women was common in many districts in England, and that herbalists in towns found a ready sale for it. I looked up the literature of *Senecio Jacobœa* and found that it and other closely allied species, especially the *Senecio Aureus* were used by the eclectics in America and elsewhere, under the name of 'Life Root." They were said to be emmenagogues and to be useful in dysmenorrhœa and "other derangements of the female genito-urinary organs." In an old herbal I found it stated that the drug was of such value in menstrual disorders that it was popularly known as the "Female Regulator." In another old medical work it was said to "act mildly" and without producing any excitement to restore the catamenial flow in a manner so natural that the patient was scarcely aware of being under the influence of any medicine. Acting on this hint I had several pounds of the plant collected and made into a one in ten tincture. My first endeavour was to ascertain the dose of this preparation and the amount which could be administered with safety. On May 14th, I took half a drachm in water three times during the day, gradually increasing the dose, until on May 29th I was taking half an ounce four times a day. Finding at the expiration of another week that it produced no effect, I ceased taking it, but one of my students who was enthusiastic on the subject took half an ounce four times a day for a month without in any way incapacitating him from performing his duties in the cricket-field. I concluded that it had no toxic effect and that it might be administered in the ordinary doses in which tinctures are given with perfect safety.

At first, my observations were made entirely with this tincture but after a time I substituted a one in one liquid extract of senecio. Some specimens of this fluid extract were made from the *Senecio Aureus* and not from the ragwort. I also made a limited number of observations with senecin, an active principle obtained from the senecios. It is a dark brown resinous-looking substance and is probably not an alkaloid. It is best administered in the form of pills, and two or three grains may be given three or four times a day. The tincture, fluid extract and active principle are apparently identical in action, and I could detect no difference in the action of the two species employed.

My first observations were in cases of functional amenorrhœa. I found that it succeeded admirably in those cases in which the menstrual function having been established and performed regularly for some months or even years was delayed or suspended, as the result of exposure to cold or some similar cause. It is to this class that the majority of my cases belong, and it is in these cases that the treatment affords the most satisfactory results. In the majority of women the period was not established until the drug had been taken for ten days or a fortnight, but in one case the patient after having missed for two months came on unwell after taking six two drachm doses. In cases in which the amenorrhœa was associated with or dependant on anæmia senecio uniformly failed to do any good until the anæmic condition had been removed by iron. In cases of amenorrhœa following parturition and suckling, senecio always answered admirably provided always that the patient was not markedly anæmic. In cases in which the menstrual flow has never been established senecio is frequently most useful, and in four cases of vicarious menstruation—the blood coming from the mouth or gums—nothing could have been more satisfactory.

I am satisfied that senecio not only anticipates the period, but that it also increases the quantity. In many cases of dysmenorrhœa it promptly relieves the pain, and not unfrequently the headache, from which many women suffer at those times. In several cases the administration of the drug was coincident with the disappearance of leucorrhœa of long standing.

Senecio is apparently not an ecbolic, in fact it is very doubtful if any drug has the property of expelling the contents of the non-parturient uterus. The following case which occurred in the practice of a medical friend in the country, is suggestive. V. R—, æt. 23, menstruated for the last time on January 12th, the period lasting five days. She was anæmic, and from Feb. 4th to March 25th took perchloride of iron in full doses. She did not come on unwell in February, and on March 5th was ordered two grains of senecio in a pill three times a day. On March 11th the dose was increased to three grains three times a day, and this was continued without intermission until March 25th. On the latter date the fluid extract of senecio in 20 ♏. doses three times a day was substituted, the dose being gradually increased on April 8th to half a drachm three times a day, on April 15th to the same dose four times a day, on April 29th to a drachm three times a day, and on May 6th to two drachms four times a day. There was no appearance of the menstrual function, and my friend for the first time entertained a suspicion as to her condition. There was, however, nothing characteristic in her appearance, there was no alteration in her usual good spirits, she was apparently not in any way depressed, and there was no history of morning vomiting or disturbance of appetite. Under the circumstances, and especially having regard to her social position, the suggestion of an examination seemed out of the question. The senecio howevever, was discontinued, and gentian and soda was given for a fortnight, constipation being relieved by a mild aperient. On June 17th she was ordered three grains of senecin three times a day which was taken for ten days, and again without any effect. On June 27th I was asked to see her in consultation. I found that the breasts were enlarged, that there was a characteristic appearance about the areola, that a clear fluid could be obtained on pressure, and that there was a solid tumour in the abdomen extending up to within an inch of the umbilicus. She was clearly pregnant and was about five months advanced. She denied all knowledge of her condition and attributed it to the medicine, but I fancy some other agency must have been at work.

In general action senecio seems to be allied to pulsatilla. Dr. H. S. Purdon, of Belfast, informs me that it is an old Irish remedy for jaundice, and that both he and his father have often prescribed it in that condition. It occurs to me that possibly the colour of the flowers may have something to do with its selection originally for this purpose.

There is, I think, very little doubt that we have in senecio and its preparations a drug which deserves to rank with permanganate of potassium and bin-oxide of manganese in its power of stimulating the menstrual flow.

◆

SOME PRACTICAL OBSERVATIONS
ON THE
EXAMINATION OF AN EAR
AND THE
ÆTIOLOGY OF AURAL AFFECTIONS.

By H. MACNAUGHTON JONES, M.D., M.Ch., M.A.O. (Hon. Cau.), F.R.C.S.I. & E.

(*Concluded*).

PART III.

IT is not necessary to delay over the care which must be taken with all diagnostic appliances used in the examination of an ear. The nozzle or tubing of the inflating balloon, the aural and nasal specula, the ear-pieces of the auscultation tube, the Eustachian and tympanic catheters, the nasal and Eustachian bougies, the tongue depressor, and post-nasal mirrors, should always be kept scrupulously clean, and passed through some disinfecting solution immediately after use. The safest plan is always to keep at hand a bowl with some carbolised or perchloride of mercury solution, into which these appliances are dropped. This secures their being cleansed by the attendant before they are required again. We cannot be too particular with regard to this matter.

Now that electric lighting has become so universal, the supply in many houses for purposes of illumination can be had from the main, and the transformer, which serves both for lighting, and heating the cautery, may be readily adapted. But where the electric light cannot be had, the Argand gas-burner with bull's eye, on adjustable bracket is sufficient for all purposes. The choice of a speculum with which to examine the meatus and membrana tympani, will depend, in a measure, upon the calibre of the canal of the former. I prefer, as a general rule those in which the funnel end is perfectly tubular. By a slight movement, every portion of the membrane may be brought within view. Delicacy in manipulation, and lightness of touch are necessary in all cases when examining an ear, but especially so when there is nervous apprehension on the part of the patient, and tenderness of the meatus from inflammation.

The most frequent obstacles, apart from any abnormality or narrowing, which contracts the lumen of the canal and obstructs the view, are collections of cerumen, dead epidermis, and discharge; hyperostoses or exostoses are more uncommon. The caution not to be misled by the metallic lustre, sometimes seen on the surface of old impacted wax, which has been pushed deep into the auditory canal, is not out of place. Nor, during its removal, should we neglect occasionally to examine the meatus, and inspect the membrane. A large grub of wax may come away, and yet other layers, both of wax and wool, be concealed. I have recorded a case where there were three such layers of wax and two of wool, in the canal, and another in which a grain of shot had remained undetected since childhood, and was discovered by me after the removal of a plug of cerumen. The precaution referred to will also prevent syringing on an exposed drumhead. In addition to the removal of any secretion or epidermal *débris*, it is well to thoroughly cleanse the ear by wiping and drying the walls of the canal, and, in certain cases, the membrane, with the aural probe or absorbent wool-holder.

It was in the year '78 that I first figured, in this journal, the original probe here shown, made for me at the time by Messrs. Weiss, and which has since passed through various crooks and twists, without any great advance in its progressive clinical development, whatever it may have gained in nomenclature. As in handling most other simple appliances, there is an art required in using this one efficiently. With a little practice and dexterity the wool can be rapidly affixed or removed with a twist of the finger, and may be rolled on the screw end of the probe in any shape or size desirable. For diagnostic and cleansing purposes the "duck's egg" shape is preferable, but for a therapeutical application, the thinner the layer of wool we use the better. This is shown in the illustration.

FIG. 1.

FIG. 2.

FIG. 1.—Aural Probe (about half its natural size.)

FIG. 2.—The same charged with absorbent wool.

I may, in passing, refer to another convenient appliance made for me a few years since by Messrs. Down Bros, and which I have already described in the *Lancet*. It is useful for diagnostic and therapeutical purposes, in the case both of the ear and nose; in short, it is a naso-oral probe. The flat end is that first employed by Bosworth for exploratory and therapeutical purposes, in the examination and treatment of the nasal cavities. This flattened end, made of platinum, is modified by being serrated at the edges to within a short distance of the extremity. It is most convenient for passing between the turbinate bodies, and into the nasal interstices. The other end, which is bulbous, has a screw thread, not continued quite up to the bulb. To both the flattened and bulbous points wool may be affixed in any form desired. The bulb point answers well for sounding the nose, determining the consistence and size of any swelling, and may be used in the external meatus for the same purpose as the aural probe. Both shafts screw into the central gilt metal tube, so as to make it readily fit into a pocket case.

FIG. 3.

FIG. 3.—Showing the probe with both ends concealed.

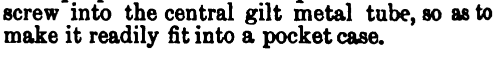

FIG. 4.

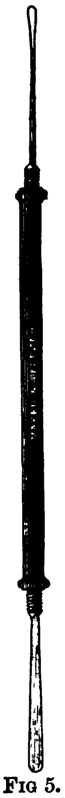

FIG 5.

FIG. 4.—Showing the same detached.

FIG. 5.—Showing the entire probe connected.

With a small rubber syringe, and the aural probe, the ear passage can in a few moments be thoroughly cleansed and dried and made ready for inspection.

A word may be said of the aural speculum. All the coloured drawings of diseased conditions of the membrana tympani, in my aural atlas, which have stood the test of universal criticism, were made through the ordinary Toynbee's speculum, and with the laryngeal reflector. This shows how unnecessary is complicated apparatus. Siegle's speculum is valuable in the detection of adhesions. The magnifying speculum, made for me by Messrs. Arnold, of London, I now constantly use. I thus described it in the *Lancet* of Nov. 18th, 1893:—

"All aural surgeons are familiar with the construction and use of Siegle's speculum. Its value in affording a magnified view of the membrane and the detection of adhesions, rigidity of the ossicles, and readily yielding portions of the membrane through the action of the pneumatic tube are well known."

For a long time, with the ordinary silver tubular speculum, I have been in the habit of combining different lenses from my trial lens-case in order to obtain, rapidly, a magnified view of the membrane, the light being thrown with the ordinary aural or laryngoscopic mirror. With very little practice a splendid view of all portions of the membrane is thus easily obtained.

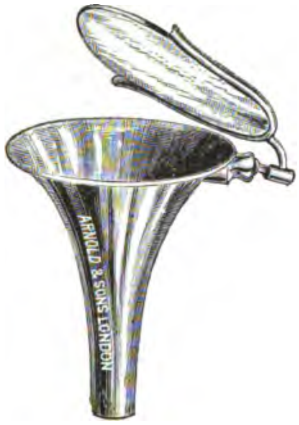

Fig. 6.

Fig. 6.—Magnifying speculum with ball and socket attachment.

It was not until quite recently that the thought struck me that such a set of lenses might be combined with a properly shaped tubular speculum. This I have done by attaching a light clip on a ball and socket joint to the rim of the speculum, into which fit three lenses 12, 14, and 16 D. The lenses can thus be instantly changed. For children all that is required is a speculum with the tubular end reduced in calibre.

Subsequently, I discovered that Dr. Ward Cousins had already (*British Medical Journal*, January 16th, 1891), devised a Magnifying Speculum (See letter to *Lancet* from me, December 2nd, 1893).

The above speculum, however, is quite different in construction. The surgeon who is not familiar with the use of Siegle's speculum may at first have little difficulty in getting rid of the reflection of the mirror on the lens which obstructs the view. After a little practice this is quickly overcome. By turning the lens obliquely (as in the instance of the ophthalmoscope) the reflection is deviated.

By this speculum we obtain, with a little experience, a clear and magnified view of the tympanic membrane, and any abnormalities in its position, colour, vascular injection, or minute perforation; also of vascular growths upon it, or any such that may be sprouting from the tympanic cavity. By the additional aid of Valsalva's inflation, we can distinctly see the slightest alterations in the curve of the membrane, in the light reflex, as well as any escape of air through the most minute perforation.

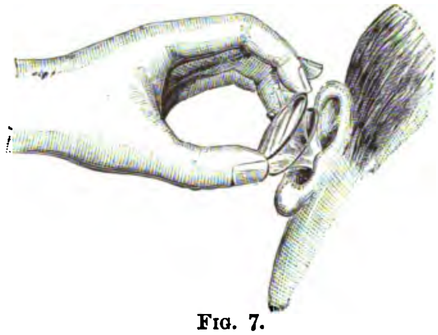

Fig. 7.

Fig. 7.—Speculum applied.

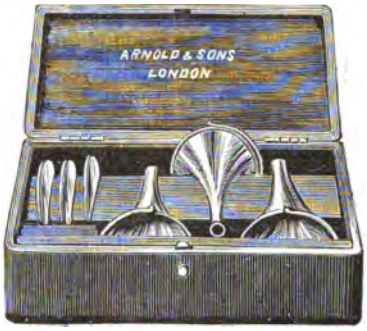

Fig. 8.

Fig. 8.—Set in case.

In this exploration of the outer ear and membrane the use of cocaine, in inflamed or sensitive states, is a considerable assistance. It may be applied with the cotton wool holder, in a ten to twenty per cent. solution, and by its aid, with but little distress, an abscess may be opened, an incision made, and the cautery, carbolic, chromic, or chloro-acetic acid, applied. The possibility of a mass of cerumen being concealed behind an abscess or swelling of the meatus should not be overlooked. I have seen this happen a few times when there was no suspicion that such a collection of epidermis and wax, the obvious cause of the primary irritation, existed.

A foreign body, in the futile effort to extract which injury has been inflicted, either to the meatus wall or tympanum, may be in great part concealed from view through swelling. Here again cocaine is of help. I have elsewhere mentioned the case of the gentleman whose drumhead was permanently lacerated in the effort to remove what was supposed to be the bone head of a programme pencil which had come off in the ear passage and was thought to have remained in. When the effects of the inflammation subsided it was found that there was nothing in the ear, and, curiously enough, a few years since a gentleman was sent to me for the same object, though no foreign substance was present. These observations are not intended to embrace principles of treatment, but I may state as a fact that I have never yet failed by patience, recurrent and well directed syringing, to remove from the ear any foreign body, and I think that that experience covers nearly every substance which is likely to find its way into the passage. It is a common practice for patients to wear small pieces of cotton wool in the ear for slight ailments; this habit is to be discountenanced, but at times, after examination, and when a journey has to be taken subsequently, it may be right that such a protection from cold should be adopted. The little celluloid protectors I have devised, which are perforated are light, clean, and handy for this purpose. They are shown in the drawing natural size.

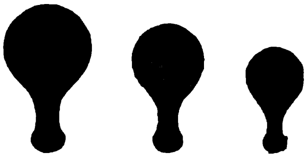

Fig. 9.—Celluloid ear protectors. (Maw.)

There is not much to be said of examination with the auscultation tube (otoscope). Familiarity with the nature of the sounds conveyed through it to the ear of the observer affords valuable knowledge with regard to collapse of the membrane, dryness or moisture of the tympanum, and perforation of the membrane, to diagnose which latter however we have occasionally to resort to Politzer's inflation. Negatively, it informs us of the non-entrance of air into the tympanum through the Eustachian tube.

Before passing from the examination of the ear itself, there are a few points of importance to refer to. The cause, duration, source, and character of an aural secretion or discharge, have to be carefully inquired into.

(1) Cause, in some probable microbal or fungoid contamination, such as influenza, malaria, foul drains, zymotic inflammation, or the fungus aspergillus ;

(2) Duration, as indicating the depth to which the destructive processes have extended, and the probable involvement of the parts about the tympanum. This suggests an acquaintance with the previous steps taken for its suppression ;

(3) Source, whether from the meatus, with the drum-head intact or perforated; the tympanic cavity, and the part of the latter which secretes the discharge ; in other cases the mastoid antrum as a possible source has to be remembered, and the strong probability of chronic suppurative conditions of the middle ear, extending to this cavity, must be kept in mind ;

(4) Character, whether sanguineous, coloured, transparent, and glairy, purulent or mucoid ; its quantity or odour ;

The obstinate persistence of chronic suppurative discharges of the ear is notorious, and the quantity that may be secreted in the twenty-four hours is very great. Blood is sometimes rapidly effused in attacks of acute periostitis extending to the tympanum. This is generally associated with most severe pain. It likewise frequently accompanies polypus and granulations of the meatus or tympanum. In injuries to the labyrinth, or extension to it of inflammation from traumatism of the middle ear, the quantity of discharge of a semi-purulent nature is very great. The fœtor of a discharge is another feature of moment. It is most persistent and characteristic in old suppurative states of the middle ear, and when we have apparently washed out all discharge and cleansed the tympanum it may still be detected by means of the aural probe and cotton-wool, a clear proof that the cavity still contains septic material. This knowledge is valuable when we are thoroughly cleansing and drying for the application of an antiseptic the tympanic cavity. No patient's life is safe who has any fœtid discharge from the ear, and, indeed, the same may be said both of aural polypus and exuberant granulations in the cavity of the tympanum. At any time mastoid inflammation, with all its consequences in extension to the brain, or the occurrence of septicæmia, may set in. And, if, with the presence of an old discharge, a patient comes suffering from a boring or radiating pain about the ear or in the head, or who even without this symptom, is attacked by giddiness, with signs of general malaise, suspicion should at once be aroused that the mischief is extending to the brain, and an ophthalmoscopic examination be made so as to detect any corroborative evidence in the presence of optic neuritis, though such correlative proof is by no means necessarily to be expected. Under any circumstances increase in temperature, nausea, or furred tongue, with constipation and possibly lowering of the pulse, should excite apprehension. Obviously, all these observations apply with double force in the case of children, in whom some old ear discharge is apt to be overlooked, and in whom the earlier symptoms are liable to be confounded with the consequences of dentition, gastric or typhoid fever, worms, or meningeal inflammation arising from other causes.

One axiom, however, is universally applicable to all cases, viz., that every chronic discharge from an ear is an indication of danger, quite apart from any influence it may have on the hearing or other inconvenience that may result from it. And this further lesson it is well to insist on—that when head symptoms suddenly set in after a short illness, even though there be no present indication of aural mischief, and the attention be diverted to other organs, inquiry should be made into the history of any previous affection of the ear, if such there has been.

Since the naso-pharynx has come to be rightly regarded for clinical purposes, as a portion of the organ of hearing, an examination of the nasal passages and pharynx is part of every complete investigation into the cause of deafness and tinnitus. I have gone to some trouble to collect evidence, not yet published, which the experiences of others, as well as my own, has furnished of the influence exerted through turbinate hypertrophy on the hearing. Individually, I am convinced that the relation, as cause and effect, of certain forms of nasal obstruction in producing deafness has been greatly exaggerated, and I am further convinced that mutilation of the nose for the cure or relief of deafness has been far too widely practised.

At the same time, there can be no doubt that considerable nasal obstruction does predispose to loss of equilibration of the air in the tympanic cavity, while collapse of the membrane and closure of the Eustachian tube, follow from the same cause. Therefore, with Duplay's speculum, it is well to look for deviations and spurs of the septum, and those various changes in the turbinate bodies, leading to their enlargement—the results of hypertrophic rhinitis. Nasal polypus, as is well known, is rarely a cause of deafness. In examination of the nose, the probe to which I have alluded, and the various nasal bougies, especially those semi-cylindrical and grooved ones of Stoker (made by Messrs. Down Brothers), will be found most serviceable. Were it not still of occasional occurrence that a prominent and flabby turbinate bone is mistaken for polypus, it would be unnecessary to allude to the possibility of falling into such an error.

In concluding these necessarily condensed remarks, I must say a word with reference to hypertrophic tonsils and adenoid growths in the naso-pharynx. With reference to the former, it is my invariable practice, in any case of deafness, to reduce these by means of the guillotine. Hearing is generally improved, and I have never had any bad result. With regard to adenoid growths, when type of face, contracted nostril, nasal pronunciation, and snoring in sleep point to their presence, I make, when possible, a rapid *digital* examination of the posterior nares. When this cannot be done, I have the patient anæsthetised, and explore in the same manner by the finger, operating if necessary at the time. There is no operation in surgery that I know of which is attended with more permanent benefit than this of removal of adenoid vegetations. The breathing becomes normal, chest formation and respiration are improved, hearing, is frequently restored, defective pronunciation ceases and the whole aspect of the patient is changed for the better.

ON CASTRATION IN FEMALES:
ITS FREQUENT INEXPEDIENCY AND THE SIGNAL ADVANTAGES OF CONSERVATIVE SURGERY IN THESE CASES.

By C. H. F. ROUTH, M.D.

Part I.

I shall start my paper to-night by asking what to some may be an aphorism, and when addressed to gynæcologists, may savour of inaptitude. This may be so, but still I believe this question, at least in its totality, has not been yet answered satisfactorily. It is simply what are the functions of the ovary and tubes? What purpose do they serve in the animal economy? The tubes it will be said convey the ova to the uterus. The ovary secretes the ova; but how does the free tube which floats in the cavity of the abdomen seize hold of the ovary to receive the secreted ovum? The most recent authorities cannot decide this point. Probably it is due to a current running from the peritoneal cavity to the uterus, set up by the action of the intra-tubal and uterine cilia. Possibly the erectile muscular tissue of the Fallopian tube, under the influence of the maturation of the ovum, is also a factor in the process. But again, has the ovary no other function? Does it secrete any other substance besides ova? *A priori* we should imagine it did, and further, following the example of the kidney which excretes bile in jaundice, it may, under certain circumstances, secrete some other substance to compensate for other defective glands.

There are at least five other glands in the human body which excrete or secrete some substance from the blood, and which, in its changed form, passes into its efferent blood again. They are the *spleen*, the *thymus* gland, the *thyroid* gland, the *supra-renal capsule*, and the *pineal gland* or pituitary body. All these must exert a very powerful influence upon the human organism. It is true some of these may be extirpated in part or in entirety, and life appears to be little affected thereby. But this can only be the case where other organs take up a compensating action, as in the case of the kidney excreting bile in jaundice. An artery may be tied or be plugged by embolism, and the parts supplied by it will for a time suffer and be ill nourished, but by and bye new channels will result from the enlargement of arteries in the neighbourhood, and the parts will reacquire their original development. It they do not, a permanent injury will result to the individual.

Of late years we have come to know that two of these glands at least do perform a very essential part in the economy. Disease of the supra-renal capsules gives rise to Addison's disease—which generally, producing discolouration of the skin, which is mottled sometimes throughout, and intense debility, ends generally fatally.

So likewise disease of the thyroid, whether hypertrophic, as in the formation of goitre, with insanity in its course to offspring, or atrophic, as in *myxœdema*, should be borne in mind. This last disease, indeed, teaches us much as to some secretion in the thyroid, which if not there to be taken up by the blood and reabsorbed, is fraught with great danger. In myxœdema we know that the symptoms are all due to the absence or disease of the thyroid gland, which, although destitute of ducts, must produce some substance in its parenchyma, which is reabsorbed by the blood and utilised by it. If this substance, whatever it be, is wanting, the group of symptoms known as myxœdema result. But experience has shown that, if beef tea made from the thyroid gland is drunk, or a sterilised essence of it be made and injected subcutaneously, or if a sterilised portion of another animal's thyroid gland is thrown into the belly (although the last course is somewhat perilous), then the symptoms of myxœdema rapidly pass away.

In the case of the liver we have another analogous fact which helps us in this inquiry. Sugar is converted by some process, into a substance very like starch, and then re-converted into glucose for consumption in the lungs.

The pituitary gland, according to Dr. W. Lloyd Andriezen (*British Medical Journal*, Jan. 13th, 1894, p. 56), consists of at least three parts, chiefly an anterior lobe which is a type of a secreting structure of epithelial cells with many ducts terminating in one. It must be of great use in the economy of the nerve tissues just as much as the oxygen borne by the water current is—and may act either upon the nerve tissues for their oxygenation; or destructively to neutralise and render innocuous other waste products of the activity of the nerve tissues. The second part of this body is a water vascular duct, the third a posterior sensitive nervous lobe which later in life become obliterated in all but larval acraniates or amocoetes. Quite recently Henrot and Marie have drawn attention to the hypertrophy of the pituitary gland found in patients dying with acromegaly.

We now pass on to more modern research and upon more questionable ground, although the question is most interesting. We are all I suppose well acquainted with the late researches of Brown-Séquard. Briefly it is to the effect that there is a certain principle which can be extracted from the testicle of animals, and which when sterilised and injected subcutaneously in a human being is in many cases a recuperative remedy, specially in cases of mental decay.

Now I am not going to praise up this system, but I have read much that Brown-Séquard himself has written upon the subject, also Dr. L. H. Gorzet's book on "La vie prolongée par la méthode Brown-Séquard." I cannot consider that when many medical men from different parts of the Continent admit its efficacy, and instance cases, that it is all like the medical battery illusion. There must be a substratum of truth, for doubtless the secretion of an organ which effects such changes in life and nutrition, should have we must suppose *a priori* a peculiar influence. It is true that among ourselves, probably owing to the ill savour of the subject, it has not been fully tried as in other countries, but some have had the courage to do so. The subject was brought up before the Harveian Society by Messrs. Waterhouse and Shaw; and their opinion after trial was upon the whole favourable. More lately Dr. R. W. Felkin, in a paper (published in the *Edinburgh Medical Journal* for February, 1894), and entitled "Abstract of a Note on the Administration of Organic Extracts," speaks of the value of brain and orchitic extracts, prepared by Messrs. Duncan and Flockart and Co., in Edinburgh, and Burroughs, Wellcome, and Co., in London. He gives two cases of paralysis and one verging on delirium tremens cured by brain extract. Also three cases of epilepsy greatly benefited, if not cured. And then refers to orchitic extracts and their effects. He alludes to certain habits of the savages in Central Africa who feed on raw orchitic glands and their secretion to gain prowess. And like myself he believes that this gland and the ovary do secrete some peculiar fluid, which absorbed in the system, strengthens it in some manner, and that the sufferings induced upon many women by castration, are due to the loss of this substance, although in time the effect may pass off. Melancholia and hypochondriasis are the two resulting diseases he mentions. For my part I should say these effects only pass off when other glands supply the spermin and compensate for the loss of the action of the two glands above named. Whether, therefore, we speak of the Brown-Séquard vaccine or the inorganic salts they do seem to do good in some manner such as suggested. I cannot say more, nor indeed can I say less. These agents are not always reliable, and frequently fail, but they also do sometimes bring about marvellous results But contrariwise we must not ignore the converse experiments of opponents. It is alleged by several persons that if water be injected subcutaneously it will produce the same results; that it is in fact the result of a mental suggestion. Now I do not deny this, especially when attested by gentlemen connected with the Queen Square Epileptic Hospital. But the same thing has been observed in persons who have been accustomed to subcutaneous morphine injections where water has been substituted. Yet morphine is not inert.

Side by side with these results of success by the mere subcutaneous injection of water, we may mention those cases of fibro-myoma of the uterus which disappear. Mr. Lawson Tait refers to several cases; one where, after dilatation of the cervix, and under the influence of ergot and bromides it disappeared; another in which he removed a cystoma by abdominal section, and a fibroid she had besides disappeared, and she became pregnant. Two others in which abdominal section was performed, but the tumours only handled, and yet both disappeared. More lately Mr. Alban Doran has called attention to cases which have disappeared spontaneously under various influences, and Dr. Greig Smith has given several examples of even malignant tumours, which after the opening of the abdomen found to be irremovable have yet suddenly been absorbed and disappeared. Then there is a remarkable case quoted by Dr. Petres, of Bordeaux, which may be described as Mental Impressions *versus* Oophorectomy (*Lancet* 2, 1890, 681). He operated on a case of a woman suffering from violent neurotic manifestations, the result of fright by fire. Mr. Charlevin, of the Cremona Hospital, told her that nothing short of castration would cure her. Thereupon she became rampant to have this operation done, and so a mock operation was performed to calm her. She was anæsthetised, and a superficial cut made in the abdominal wall, which was afterwards dressed in the usual way with iodoform, &c. From that day all sickness, vomiting, insomnia ceased, and she gained health and strength.

Now this reflection must be made on these cases. If they are true, and of this there is no doubt, would these successes justify us in opening an abdomen, handling the tumour, and doing nothing more, but closing the abdomen, in all other cases, and this in the face of so many successful cases of ovariotomy and hysterectomy? I trow not. The same is true of these water subcutaneous injections as opposed to injecting a legitimate drug. It is not, however, a savoury idea, and I must confess to being actuated by a repulsive dislike to use these drugs, not because it is a vaccine and because it is taken from a lower animal, a common objection urged by foolish anti-vaccinators, but because I have the same feeling when kidneys or livers, or other internal organs are set on a table as luxuries for the purpose of a meal.

In connection with these injections, however, let me call your attention to some more recent discoveries.

In a paper published by Poehl, *Berlin Klin. Woch.*, No. 36, 1893), and referred to in the *Br. Ass. Journal Epit.*, p. 63, Oct. 14th, 1893), this principle which is called "spermin" is stated to have been found in the thyroid and thymus glands, the spleen, ovaries, and blood, as well as in the testes, from which tissues it has been extracted as an insoluble spermin phosphate. These crystals are known as the Charcot-Leyden crystals. Poehl believes them to be a leucomaine, the product of retrogressive metamorphosis of albumens. As such it is a constituent probably the active one in Brown-Séquard's vaccine. Unfortunately, it has not yet been produced stable in quality, nor has its use always been followed by the same results. Now Poehl believes it to be a most powerful intra-organic restorative of the oxidising properties of the blood. His reasons are the power possessed by a small proportion of spermin to oxidise large quantities of metallic manganese, its restorative power in chloroform poisoning and in these cases where by section of the spinal cord a reduction of such intra-organic oxidation takes place. Poehl further quotes observations to show that the favourable action of spermin is marked more in patients suffering from anæmia, diabetes, scurvy, in which auto-intoxications are manifest as the result of an accumulation of retrograde products. Finally, he states the effect of spermin injections is to increase the quantity of nitrogenous products excreted by the kidneys. Its action also in the cholera bacillus in like manner explains its tonic action. If it fails sometimes, as when it is found to be excreted in spermin phosphate crystals by the mucous membranes, it is probably due to *diminished* alkalinity of the blood, and this precipitation of the spermin phosphate has its influence on the system thereby suspended or lost. Hence the advantage of combining alkalies in its employment.

Is this principle the same as the Brown-Séquard vaccine? M. Brown-Séquard believes it may be, but he is not certain, but he thinks his own vaccine more sure and effective.

But what I have to do here is neither to recommend one nor the other, but to show that this principle must exercise a powerful influence on the animal economy, and its presence in the blood is not only a desideratum but a necessity.

But now *per contra* have we any evidence that spermin taken from a woman has when used in like manner and injected subcutaneously a similar effect? On this subject Dr. Goizet makes the following observation:—"My personal experiences, he says, on the juice extracted from the ovaries of animals demonstrate that this juice has *no* effect either on male or female. The female does not possess in her the power at the disposal of the male, no part of a female being contains a fluid similar to the testicular juice. It belongs exclusively to the male, although it is secreted under female influence," p. 91. It is difficult to reconcile this opinion with the following: An American lady, M.D. of the Faculty of Paris, Mrs. M. Augusta Brown, undertook with great courage the subcutaneous injection of ovarian juice taken from animals. She performed her experiments upon a large number of women. Her results were extremely interesting. She selected the ovaries of rabbits, removed from the abdomen of living animals, following the same rules given for the testicles, sometimes using the Pasteur filter by paper. The injections were made subcutaneously on, thorax or abdomen. Both instruments and vessels being antiseptically prepared. She treated in this manner more than a dozen women affected with extreme debility caused by age, insomnia, hysteria, uterine affections, &c. In all she found great gain of strength, in others restoration of sleep, stoppage of the hysterical attacks and cardiac palpitations, and an amelioration both of digestion and nutrition. In one remarkable case of an old woman who had possessed a splendid voice, but had lost it, the ovarian juice subcutaneously injected caused it to return with all power. Mrs. Brown found, however, that six or seven injections were often required. Mrs. Brown tried to have it absorbed over a portion of skin previously blistered, but the results obtained were much less favourable. The conclusion arrived at was that the effect of injection of ovarian juice subcutaneously was identical with injection of testicular juice, but less powerful.

Such a conclusion is in keeping with the presence of spermin in the female ovary. I do not mention the above-recited facts with a view of recommending the practice; that is no part of my subject, but it would have been a manifest contradiction to Poehl's views and the discovery of spermin in the female organs, if some such effect had not been produced. The important conclusion I draw is that spermin does exist in the female ovary, as well as other glands, and has a powerful recuperatory influence on her being. I am glad also to find that Dr. Martin, in his very able paper on the nerve theory of menstruation, published in the last quarterly number of our Transactions in the second conclusion drawn as to the cause of the symptoms produced during change of life, says: "It is probable that the ovaries, like the liver and thyroid gland, modify the blood circulating through them and add to the blood some peculiar product of their metabolism. It may be that some of the climacteric symptoms are due to the loss of this substance from the system." I should venture, perhaps, to refer to this corollary in rather a more absolute sense and say it would be very singular if the ovary did not, like other glands, secrete or excrete something useful for the processes of the economy, and which if it failed to do, would not only entail pain and disorder in the system, but produce abnormal phenomena culminating occasionally in insanity.

We know that some very analogous, albeit different results, are observed in castrated men. It is well to refer to these for comparison.

In the *Medical Times and Gazette*, Jan. 26, 1861, on Eunuchs, we read: Castrated persons have many defects which are peculiar to them; they have a bad odour, a yellow colour, furrowed cheeks and feminine voice; they are unsociable, deceitful, and rascals, and are never known to practise any virtue. ("Cours d'Opérations par Dionis.")

Eunuchs are the vilest creatures of the human race, cowards and deceitful, because they are weak, envious, and spiteful because they are unfortunate. (Benoit Bojon.)

J. E. Beauvoisin says, black eunuchs are brutal animals without any instruction, and live like wild boars in their lairs. These ferocious animals seem to think they may do what they please, and are ready to sabre those who do not get out of their way. White eunuchs are less savage.

In appearance they come to lose the shape of men, some to resemble females in the development of several bones, also become gross and fat. Their muscular force and courage, like animals, is diminished. What a difference in these respects between a bull and an ox, a ram and a wether, a cock and a capon! According to Arnabe (lib. v), they are generally weak and invalids, and subject to hæmorrhoidal discharges which assume a periodic character, as if to make up for the inutility of the blood towards the development of testicles and beard. . . . Castrated individuals are more sensitive, more obnoxious to diseases of nerves and low spirits, and affected so as often to faint on the slightest excitement.

It is but right to add that History records a few exceptional cases. One General of Constantine the Great, and also a celebrated Minister of State, were eunuchs, but they were extremely wealthy, and whether they were complete eunuchs, or operated upon in later life, is not stated. It is also said that they do not suffer from gout, and rarely from eruptive and inflammatory diseases. Lepretre indeed recommends castration in cases of elephantiasis, and the priests of Cybele were in the habit of curing mania by castration, while in certain Swedish villages it is practised in cases of satyriasis and spermatorrhœa as a curative measure.

As a reverse in the physiology of a perfect man, the following opinion is given, which is for the man, although in other words is the same conclusion to which we have referred as appertaining to the physiology of woman, viz., a memoir on the effects of castration on the human body, by Dr. Bojon, Professor of Anatomy and Physiology at the Imperial Academy of Genes, 1813. Stress is especially laid upon the fact that it is by the reabsorption of the sperm that is due the last degree of perfection in our formation; but we must bear in mind that these spermatic atoms of the blood, before they can be regarded as such, must be elaborated and secreted by the testicles themselves, carried into the spermatic vesicules, absorbed in the lymphatic vessels, which, transmitting them in the sanguine system, gives the last stroke to perfection to the animal machine.—P. 12.

(*To be continued.*)

Selected Prescriptions and Therapeutic Notes.

114.—For Impetigo:—

℞ Ungt. sulphur., ʒij;
Ung. zinci ox, ad ℥j.

M. This application can be employed freely for impetiginous eruptions, and is particularly of service for very extensive cases in which mercurial preparations are contra-indicated owing to the risk of poisoning taking place from absorption.

115.—For Lichen Urticatus. A similar ointment containing usually a larger proportion of sulphur gives great relief, especially if the itching papules be first pricked or scratched with a needle.—Dr. Eddowes (London).

116.—Guaiacol in the Treatment of Orchitis:—

℞ Guaiacol, ʒss;
Vaselini, ad ℥j.

M. Smear some of the application over a piece of lint and apply it to the scrotum. The pain of the inflamed testis will be much relieved, the relief lasting several hours. The dressing should be renewed twice or thrice daily.—Balzer.

117.—A New Treatment of Pulmonary Tuberculosis:—

Dr. Cohn, of Hamburg, has found ichthyol very useful in the treatment of pulmonary tuberculosis. He administers the drug in the following form:—

℞ Ichthyolis;
Aq. destill, āā ʒv.

M. The patient begins to take four drops of this solution thrice daily, and then the dose is increased by one drop daily until the maximum amount of forty drops three times a day is reached. The best time of administration is before meals. Generally speaking patients become readily accustomed to the disagreeable taste of ichthyol, but a mouthful or two of black coffee is very efficacious in removing the taste. The latter is said to be far superior to creosote or cod-liver oil.

118.—Useful in Dentalgia:—

℞ Tinct. gelsemini, ♏xv;
Tinct. ferri perchlor, ♏x;
Syr. aurantii, ʒss;
Aq. ad ℥j.

M. For one dose. To be repeated thrice daily.

119.—For use in External Hæmorrhoids:—

℞ Chrysarobin, gr. xvj;
Iodoformi, gr. vj;
Ext. belladonnæ, gr. xij:
Vaselini, ʒvj.

M. A small quantity to be applied to the swellings several times daily, the parts having been previously washed with a solution of carbolic acid (1 in 5).—Kossobudski.

120.—For Impetigo:—

℞ Plumbi acetatis, gr. viij;
Acid hydrocyan dil., ʒij;
Sp. rectificati, ʒss;
Aq. destil, ad ℥viij;
M.

Transactions of Societies.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Surgery.

Meeting held Friday, March 30th.

The President, Edward Hamilton, President of the Royal College of Surgeons in Ireland, in the Chair.

CASE OF LACERATED WOUND OF THE UPPER THIRD OF THE THIGH.

Mr. **Pratt** read a paper on a case of lacerated wound of the upper third of the thigh in which the great sciatic nerve was divided and much torn, necessitating resection of about an inch of the nerve and subsequent nerve-stretching before sutures could be applied. After the cut ends were brought together they were sutured with carbolised silk in a very small needle; the divided muscles were then united in the same manner, and the skin brought together with pins, the whole dressed with iodoform and alembroth gauze. The man had recovered cutaneous sensibility altogether and muscular power to a considerable extent.

Dr. **Myles** said that he did not consider this case absolutely successful. The injury occurred two years ago, and regeneration, if it were to take place, should have done so by this time. Restoration of cutaneous sensibility alone was a fallacious test owing to the existence of recurrent sensibility through the union of nerve filaments of the divided nerve with filaments of intact nerves. He had treated a man who had all the structures in the front of the wrist, with the exception of the tendon of the flexor longus pollicis, severed, in which he sutured the ends of the median and ulnar nerves. In a few days the man had partial sensation in the area supplied by the median, and this he attributed to communications between the radial nerve and the palmar cutaneous branches of the median. In the region supplied by the ulnar nerve sensation was never restored, neither was the muscular power ever regained, and the interosseous spaces wasted and remained so. He had been extremely careful to bring the divided ends in accurate apposition and to secure them by numerous fine sutures through the nerve-sheaths. In two other cases in which he had operated—one a boy whose anterior tibial was severed, and another a patient who sustained a compound fracture in the neighbourhood of the elbow—muscular power was never regained.

Dr. **Brooks** said that in Dr. Pratt's case he thought the restoration of sensibility was through the great sciatic nerve. In the hand there was a considerable area of skin which had a double nerve supply. Adjoining nerves invaded each other's territory. This was not so in the case of the foot. The long saphenous nerve—the only cutaneous nerve in that region not derived from the great sciatic—supplied a small area of skin just beneath the internal malleolus, and he had never been able to trace it along the inner side of the foot to the great toe. He mentioned a case recorded by Surgeon Yenkith in the *British Medical Journal* of a soldier whose ulnar nerve was divided above the wrist. Several months afterwards the ends of the divided nerve were brought together, and sensations, which had been completely lost in the little finger and part of the ring finger, returned.

Dr. **Wheeler** called attention to a case recorded by Mr. Wheelhouse of recovery of muscular power and sensation after division of the great sciatic and subsequent suture of the ends. He narrated a remarkable case of an officer whose musculo-spiral nerve was cut, and several months afterwards, on cutting down on the nerve, the ends were found widely separated and unable to be brought together. By the advice of the late Mr. Corley he divided the shaft of the humerus and resected a portion of it, and was then able to bring the ends of the [illegible] together. Recovery was perfect in every respect [illegible] regards power and sensation.

Dr. **Pratt**, in reply, said that cases of primary nerve suture immediately after receipt of the injury were, as a rule, much more successful than suturing the ends together some months later.

THREE CASES OF POPLITEAL ANEURYSM.

Mr. **Lentaigne** read a paper detailing the history of three cases of popliteal aneurysm which he had cured by ligature of femoral artery after compression and flexion had been tried without success. One of the patients was a very old man (seventy-seven years), and was the subject of advanced and almost universal atheromatous disease of the larger arteries. Another of the patients was suffering from well-marked aortic regurgitation, and the third was a young man of twenty-four, who was in good health in other respects. Catgut ligatures were used in all the cases, but in the case of the old man the ligature, which was very thick, was previously softened by immersion in carbolic lotion, five per cent. In all the cases the course was perfectly aseptic, and the wounds gave absolutely no trouble whatever. In two of the patients there was noticed a small patch of gangrene on the front of the leg just above the ankle before the operation; this was caused by the pressure of the strap employed to keep up treatment by flexion. In all three cases the entire limb was asepticised before operation, and after operation was dressed in a huge antiseptic dressing, under which the gangrenous patches separated without suppuration, leaving a healthy ulcer underneath, which quickly healed under treatment. In all the cases flexion was systematically employed for some time before the operation with a view to setting up free collateral circulation at the knee-joint in the event of its failing to cure the aneurysm itself.

The **President** referred to the comparative rarity now of cases of popliteal aneurysm. He also spoke of the great improvement in the operative treatment due to the introduction of antiseptic surgery.

Mr. **Wheeler** said he was surprised to hear that Mr. Lentaigne's patients suffered severe pain when digital compression was tried. In several cases he had seen where this treatment was tried they never complained. In a case he had under observation at present he had refrained from operating, as he noticed that the articular arteries were enlarging and establishing a collateral circulation, and this was always looked upon as a sign that the aneurysm would probably cure itself.

Dr. **Brookes** asked Dr. Lentaigne were the occupations of his patients such as required them frequently to assume the squatting posture, as in gardening, in which position the popliteal artery is sharply bent.

Dr. **Myles** said that when the leg was fully flexed the artery became tortuous, and accordingly the sharpness of the bend was lessened. He thought that Dr. Lentaigne was very fortunate in the case, in which there was extensive atheroma. He recalled the case of a man whose arteries were in a similar condition, and who sustained an injury to his brachial artery, which resulted in an aneurysm. Compression was tried without avail, but caused some cellulitis; and the artery was finally ligatured. Secondary hæmorrhage followed, requiring ligature higher up. Hæmorrhage again occurred, and the artery was again ligatured, but the patient succumbed to repeated hæmorrhages. He thought that it was doubtful whether compression antecedent to operation was of benefit.

Mr. **Swan** said he thought that syphilis and flexion were regarded with too much importance as causes of aneurysms. The Indians who squatted all day on their heels, and many of whose tribes were all but universally affected with syphilis were, according to Dr. Armstrong, exempt from aneurysms.

Mr. **Franks** narrated the history of a man who had a popliteal aneurysm, and in whom, after having tried compression and flexion, he ligatured the superficial femoral artery at the apex of Scarpa's triangle. Pulsation returned in the aneurysm after some days, and he was forced to do the operation of Antyllus. The vessel was tied above and below, and the aneurysm was excised. The man a week later got dry gangrene of his foot, and he had to amputate below the knee. He was unable to understand why the latter operation caused gangrene while the former did not.

Dr. **Doyle** advised the use of iodide of potassium internally in cases of atheromatous arteries.

Dr. **Thompson** said that he thought one of the reasons Mr. Lentaigne's case of aneurysm in a subject affected with extensive atheromatous disease was so successful was owing to his having used a thick soft ligature which did not tear through the coats of the vessel.

Mr. **Lentaigne**, in reply to Dr. Brooks, said that the occupations followed by his patients did not necessitate much squatting. One was a vandriver, another a law clerk, and the third a labourer in Guinness' brewery.

The Section then adjourned.

◆

BRITISH LARYNGOLOGICAL AND RHINOLOGICAL ASSOCIATION.

Meeting held Friday, April 13th.

Dr. MacIntyre (Glasgow), President, in the Chair.

CURE OF ASTHMA BY REMOVAL OF NASAL POLYPI.

Mr. Mayo Collier read notes of a case which, he said, exemplified the effect of nasal obstruction in the production of pulmonary troubles. The man, who was present, came to him in January, 1892, with the history of having for upwards of ten years suffered from asthma. He had been for four years under the care of various physicians without any benefit. He occasionally had very severe attacks, and was at times incapacitated from following his occupation. He found the whole nasal cavity blocked by a number of polypi which pressed against the septum and effectually obstructed the passage of air. These he removed, and from that date there was not the slightest return of the asthmatic symptoms, the immunity lasting until January of the present year. Since this date his troubles had returned in an intensified form, and his dyspnœa, which was at times intense, troubled him day and night. He was almost unable to cross the room or to go upstairs unaided. For various reasons he had postponed coming to London, until a fortnight ago, when he found that the polypi had reformed on both sides. He removed the polypi on one side at the first sitting, and the result was so far satisfactory that the patient had not been troubled with any asthmatic symptoms since.

Dr. **McNeill Whistler** observed that for the physician to omit examining the nasal cavities in cases of asthma would be to omit one of the most essential parts of the investigation, especially in view of the brilliant results that had followed the treatment of local nasal conditions in this association. They did not, he admitted, always obtain the admirable result which the author had succeeded in obtaining in this instance, but it was evident that when the condition was one of long standing secondary changes might have occurred which would serve to perpetuate the condition after the primary cause had subsided or been relieved.

Dr. **Woakes** pointed out that specialists in their department did not often see cases of asthma until the condition had existed for a considerable period of time. Under these circumstances it often happened that pathological changes had supervened as a secondary consequence, and these of course were unaffected by the removal of the primary cause. This was often the case in asthma originally dependent on intranasal conditions. If the nasal condition were taken in hand early enough uniform and marked success would, he thought, follow in every case. It must be borne in mind that exacerbations of asthma might follow acute attacks of old-standing nasal trouble.

Dr. **Dundas Grant** said that while, when asthma existed in association with nasal obstruction, they would certainly be justified in removing the obstruction, it would be imprudent and unjustifiable in every such case to promise a cure. It was, in fact, impossible beforehand to determine what would be the effect of the intervention in respect of the pulmonary trouble.

Mr. **Wingrave** alluded to the alleged influence of the vagus in the production of pulmonary troubles associated with nasal obstruction, and pointed out that as the vagus is an efferent nerve it could not have the action on the respiratory muscles that had been claimed for it.

Mr. **Collier**, in reply, observed that was due to spasmodic contraction. The nose had a certain function to fulfil in respect of respiration, viz., to warm, moisten, and filter the air which passed into the lungs. If in consequence of disease it failed to fulfil this function, the pulmonary apparatus proper suffered and the muscular fibres of the bronchioles might be stimulated into pathological activity. Mr. Wingrave, in denying the existence of any communication with the vagus, must have forgotten that the vagus sent ramifications to the mucous membrane of the larynx as well as branches to the pharyngeal plexus which innervated most of the laryngeal muscles.

CASE OF ABSCESS OF THE FRONTAL SINUS.

Mr. **Collier** related the case of a patient who came to the hospital with intense redness and swelling over the left eye, extending over the mid-frontal region. The temperature was 103° F. He diagnosed abscess of the frontal sinus, and on exploring with a probe in the region of the inner and upper wall of the orbit, he ultimately succeeded in passing the probe through a small opening into the denuded frontal sinus. Having enlarged the opening, he passed the probe down into the nose and inserted a drainage tube. The symptoms then subsided. He left in a silver drainage tube for some time, and all went well, but as soon as it was removed the opening closed and the symptoms recurred. He pointed out that there was a condition of chronic nasal obstruction, characterised by the approximation of the turbinated bones together with the other effects usually resulting from long-continued atmospheric pressure consequent on prolonged nasal obstruction. This condition he proposed to remedy as far as possible, and he showed the patient now so that they might be enabled to note the condition before as well as after the further operation.

EARLY EPITHELIOMA (?) OF THE LARYNX.

Mr. **Collier** also showed a woman, æt. 46, who came to him complaining of slight hoarseness and cough. The vocal cords had a serrated margin with some ulceration and the case looked like one of tubercle. She improved to some extent under cod-liver oil and tonics, but six months later she returned complaining of hoarseness. There was marked redness of the ventricular bands, and on attempting to phonate there was manifest inability of the left cord to come to the middle line, owing to fixation of the arytænoid cartilage. In view of the fixation of the vocal cord, the chronicity of the disease and the tendency to anæmia and loss of flesh, he thought that the infiltration of the tissues surrounding the arytænoid cartilage was probably epitheliomatous.

Dr. **MacIntyre** referred to a case of Dr. Hector Mackenzie's in connection with which attention was called to this fixation of the arytænoid cartilage as an early indication of epithelioma. He pointed out that the question of diagnosis was exceptionally important in such cases, for if on the one hand it was essential that valuable time should not be lost, the operation of removing the larynx was one of considerable gravity, one, in fact, that they would not care to undertake unless fairly sure of the malignant nature of the disease.

A DOUBTFUL CASE.

Mr. **Collier** also showed a man, æt. 60, who presented a peculiar ulcer of the palate involving the right posterior pillar of the fauces approaching the anterior pillar and reaching as far as the last molar tooth. Behind, the ulcer presented a clean cut edge while anteriorly the edge was covered with granulations. Anti-syphilitic treatment had remained absolutely without effect, and there was nothing in his or his wife's history to suggest syphilis. The lungs were quite free from tubercular deposit and no enlarged glands could be made out in the neck. The ulcer was quite painless, and he admitted that he was at a loss to know what its nature might be.

Dr. **Grant** said it looked very much like a tubercular ulcer, and suggested treatment *ad hoc*.

Dr. **Stoker** said it certainly looked like either tubercle or lupus, and he asked why the author did not remove a small portion of the tissue for microscopical examination.

Dr. **Whistler** observed that with a history extending over not more than two months, and occurring in a man, æt. 60, the chances were in favour of the ulcer being epitheliomatous.

Dr. **MacIntyre** thought the author would not be wrong if he took steps to remove the affected tissue, but he observed that the cautery was a dangerous means to employ in such cases. The effect of cauterisation was often to irritate neighbouring glands into activity in malignant cases, and thus to precipitate secondary growths.

Mr. **Collier**, in reply, pointed out that there was a margin of clearly healthy tissue all round the ulcer. One side was healing while the other was spreading. These characteristics were very unlike what one would expect in an epithelioma. Nor were the appearances consistent with the diagnosis of tuberculosis. The edges were not thickened or raised or undermined. The ulcer seemed to him just like what on the penis would be called a non-syphilitic sore, a soft sore in fact. He believed that the ulcer would heal under insufflations of iodoform.

SYPHILITIC LARYNGITIS WITH APICAL CONSOLIDATION OF ONE LUNG.

Mr. **Griffith Wilkin** related the case of a woman, æt. 33, who was sent to the hospital on February 6th for immediate tracheotomy. She was said to be suffering from phthisis. Though much exhausted by the journey to the hospital there was not much dyspnœa on admission. The illness dated from the previous August, since which time she had lost a good deal of flesh. There was no family history of phthisis. She had been married nine years, and she had had two miscarriages, one ten months after marriage, and no living child. At that time she had "erysipelas of the head and face," and her hair fell off, the throat at the same time becoming troublesome. There was a good deal of swelling of the epiglottis and false vocal cords, more marked on the left than the right. They were of a dusky colour. On examining the thorax there was evidence of consolidation of the right apex, and moist sounds were audible all over the thorax. In view of the suspicious history she was put on mercury and iodides, and from that time she had steadily improved. The signs of consolidation cleared up, the swelling of the soft tissues of the larynx gradually subsided, and the epiglottis resumed its normal appearance. The voice though still weak had regained its natural tone. He brought this case forward on account of the misleading nature of the symptoms which seemed to point so strongly to tuberculosis.

THE USE OF THE PHONOGRAPH IN DISEASES OF THE THROAT.

Dr. **MacIntyre** gave a demonstration upon the employment of the phonograph and its use in diseases of the throat. He said for many years he had taken an interest in the subject and had made a number of experiments upon imperfect machines; but lately, owing to the good offices of the Phonographic Company, he had been placed in possession of an instrument which gave every satisfaction. He explained wherein his former experiments had failed owing to the difficulties in taking records of the very fine sounds which one desired to record in such cases.

His first demonstration consisted of a series of records showing the different phonetic qualities of the voice in cases of hoarseness and the use of the instrument in teaching and distinguishing cases of hoarseness due to catarrh, new growths in the larynx, and where there was pressure upon the recurrent laryngeal nerves, such as aneurism.

Secondly, records of the various coughs were heard, and a particularly interesting group was that from pressure upon the nerves in children due to mediastinal tumours; one particular set was of extreme interest as showing the adaptability of the different parts to take on special functions where particular organs had been removed. He demonstrated cases where the tongue had been removed and where by practice on the part of the patient speech had been thoroughly restored, the whole alphabet being distinctly reproduced. In conclusion, Dr. MacIntyre described some special micro-phonographic apparatus for transmitting the sounds, and said that he had no doubt that in the near future an apparatus would be constructed whereby a number of students could hear the sounds within the body at the same time, and further that these sounds would be transmitted from the hospitals to universities or colleges at a considerable distance. He had already transmitted the sounds heard within the body many miles, and with perfect success.

◆

LARYNGOLOGICAL SOCIETY OF LONDON.

Ordinary Meeting held April 11th, 1894.

Felix Semon, M.D., F.R.C.P., President, in the Chair.

DISCUSSION ON THE CHOICE OF THE ANÆSTHETIC IN OPERATIONS FOR THE REMOVAL OF POST-NASAL ADENOID GROWTHS.

By special invitation of the Council of the Society the Members of the Anæsthetists' Society were invited to take part in this discussion.

Dr. **Dudley Buxton** thought that the best anæsthetic was that which could be quickly administered and which was capable of prolongation if necessary. Much depended upon the method of operating which was employed, but any plan which limited the anæsthetist to a definite period was to be condemned. For the majority of cases he preferred the use of nitrous oxide, followed by ether, supplemented in some cases by chloroform vapour blown over.

Mr. **Butlin** expressed the opinion that, while in some few cases nitrous oxide alone might be sufficient, there were very many cases in which, he at least, could not complete a satisfactory and thorough operation in the short time which it allowed.

Mr. **Tyrrell** advocated the use of chloroform throughout and especially in the case of children, but warned against its too rapid administration and against the induction of too deep anæsthesia.

Dr. **William Hill** referred to the danger of operating without any anæsthetic and related a case of death from fright. He thought that prolonged anæsthesia was necessary for a complete operation and that the anæsthetic should always be given by a skilled man.

Dr. **Hewitt** would employ gas followed by ether and chloroform in the longer cases, but had found that gas alone supplemented by oxygen was enough for the shorter cases.

Mr. W. R. H. **Stewart** had had large experience of this operation and had used Gottstein's curette before its regular introduction into this country. He thought that for removal of adenoids only by that method, gas with a little ether was sufficient. If tonsils were removed as well, more ether would be required. Anæsthesia should not be too deep. The anæsthetist and the operator should be accustomed to working together, but the former must be entirely responsible for the choice and administration of the anæsthetic. The lateral position was the best directly after the operation. The head need not be pulled over the edge of the table.

Dr. **Silk** considered that gas, or gas and ether, must be regarded as the safest form of anæsthetic, but the comfort of the patient and the convenience of the operator ought also to be considered. For the rapid operations gas was sufficient, but for the more prolonged ones he would begin with A.C.E. mixture and maintain by chloroform vapour blown through Junker's inhaler.

Dr. **Scanes Spicer** called attention to the possibilities of sharp hæmorrhage or of unforeseen difficulty in removing growths which might render an operation longer than was expected. He would greatly prefer the slight extra risk of prolonged anæsthesia to the possibility of a hurried or incomplete operation.

Mr. **Davis** used chloroform in children under 7 years, but never pushed it to complete anæsthesia or repeated the inhalation after the operation was once begun. After the age of 7 he used gas and ether. He advocated the practice of hanging down the head so that the roof of the mouth should receive the blood.

Dr. **Dundas Grant** referred to the recorded cases of death from chloroform, and to the danger of using too much of the drug. He claimed for gas that its short duration might be neutralised by the practice of rapid operation. The addition of oxygen seemed to him very satisfactory. He generally operated with the nail to begin with, followed by rapid removal of the parts thus scraped together by means of Schech's forceps. Recurrence of symptoms did not always prove recurrence of growth as they might be due to other causes.

Mr. **Richard Gill** thought that too empty a stomach was as dangerous as too full a one. Chloroform, which he preferred, should be regulated by the depth of the respiration and by the contraction of the pupil. Its chief dangers were from hæmorrhage, sickness, and fainting.

Dr. **Whistler** advocated prolonged and complete anæsthesia by chloroform. The patients were usually bad breathers, and hence the pharynx should be obstructed as little as possible by the surgeon's fingers.

Mr. **Bailey** observed that no positive rules could be laid down. There was danger in all anæsthetics, to children as well as to adults. Each administrator preferred his own. He generally used gas and ether and thought that all reflexes should be abolished before the operation was begun.

Mr. **Walsham** spoke in favour of complete removal under incomplete anæsthesia.

Mr. **Parker** had found that recurrence was more common where rapid operations had been performed than where prolonged anæsthesia had been induced.

The **President** pointed out that the discussion had proved the impossibility of laying down arbitrary laws on this question. The methods of each surgeon must to some extent determine the best means of inducing anæsthesia for his operations. The safety of the patient and the completeness of the operation must be the chief points to consider. A rapid operation was not always a complete one. The discussion had shown that the choice of the anæsthetic must be left free to the anæsthetist, and that no blame or "criminality" could attach to the selection of any one of them.

◆

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Thursday, March 29th, 1894.

The President, Mr. **Richard Favell**, M.R.C.S., in the Chair.

CASES.

Dr. **Knox** showed a specimen of perforating ulcer of the stomach.

Dr. **Baron** showed a case of Addison's disease.

Dr. **Clark Hartell** showed photographs and read the notes of an anomalous case of chloasma in an unmarried kitchen-maid, æt. 22. There were two symmetrical sharply defined black patches of the face, extending from the eye down to the level of the upper lip and from the nose to within an inch of the ears. On the chest there were several pigmented spots, but these were not so black as the patches on the face. The coloured areas were hyperæsthetic in an extreme degree. The chloasma persisted for some months and during this time the patient was subject to attacks of vomiting. Just before and just after an attack the discolouring was more intense than at other times.

Mr. **Snell** read the notes of a case of osteoma of the orbit.

Dr. **Porter** showed a girl, æt. 14, the subject of gradually progressive paralysis of the muscles of the extremities and trunk following an attack of scarlet fever six years ago. There was no history of previous enlargement of the muscles, there was no very marked atrophy. There was well marked lordosis on standing, and arching backwards of the spine when sat up in bed. There was loss of reaction to both Faradic and Voltaic currents, no reaction of degeneration. Knee-jerks abolished. No clonus or muscular rigidity. Family history was negative.

CASE OF TREPHINING FOR DEPRESSED FRACTURE OF THE SKULL.

W. H., æt. 2, was admitted to Children's Hospital on August 1st suffering from suppurating wound on the left side of the head above and in front of the parietal eminence. *History.*—Seven weeks previously the patient was playing near some houses which were being re-slated when a slate fell and struck the child on the head, he was conscious and taken immediately to a doctor. Four days after the accident the mother noticed twitchings in the right arm, leg, and head, this lasted a quarter of an hour (according to mother) and then he had another attack the same evening, he was unconscious whilst they lasted. The patient had these fits off and on until four days before admission when on that day he had three. The child could not use the right arm. *Operation* performed on August 3rd. An exploratory crucial incision was made, the old wound opened up and a depressed fracture was revealed, and half inch trephine was applied near to the fracture and the bone levered up, on removing the disc of bone about two drachms of pus escaped. Result.—The patient was bright and lively after the operation. August 7th.—Can move the right arm quite well, the disc of bone quite loose and pus discharging. September 5th.—Piece of trephined bone was removed, afterwards the wound healed up and the patient is quite well.

Dr. **Alfred Robinson** showed a case of "Bradycardia" in a man, æt. 71. There was a history of rheumatic gout twenty years ago, from which time the heart trouble dates. On examination the heart was found to beat at the rate of 30 per minute. The most important symptoms being periodical attacks of epileptic fits, during which complete loss of consciousness took place.

Mr. **Atkin** showed an "osteoma" removed from the left nostril of the same patient shown by Mr. Snell. The growth weighed 294 grains, was 2 inches in length, 1 inch in breadth, and 1¼ inch in depth. On opening the left nostril round the side of the nose it was found that the growth had become spontaneously detached and was simply jammed in the nostril. What had been its precise site of origin was difficult to say. There was no evidence that it had arisen in the antrum of Highmore. A naso-pharyngeal polypus having been detached the bone was pushed forwards by the finger and extracted with vulsellum forceps.

◆

LIVERPOOL MEDICAL SOCIETY.

Meeting held Thursday, April 12th.

The President, Mr. C. **Puzey**, in the Chair.

Dr. **Fingland** exhibited and explained a new inhaler for administering ether and nitrous acid gas, invented by Mr. Rumbolt, of Leeds.

Cases.

Œsophagotomy.—Mr. **Arthur Wilson** read a case of œsophagotomy for a tooth plate in a man, æt. 65. The plate, which was of vulcanised rubber, contained four teeth and was 1⅝ inches in its longest diameter. It was swallowed during sleep. All efforts at extraction failed, and it was removed by œsophagotomy about twelve hours after the accident. Great difficulty was experienced in the removal, as a sharp clip was firmly imbedded in the posterior wall, but it was at length freed by two pairs of dissecting forceps. A soft rubber tube was passed from the mouth and the patient fed regularly. Continued rapid breathing was present after the operation, but although there was no other unfavourable symptoms, the patient sank and died on the fourth day of exhaustion. Mr. Wilson invited discussion as to the advisability of using a tube in the after treatment especially, and the question whether, if used, it should be passed from nose, mouth, or wound.

Drs. Stansfield, Briggs, Samuels and Rawdon took part in the discussion, and Mr. Wilson replied.

Case of Prolapsus Uteri with Vesical Calculus.—Dr. **Briggs** mentioned a case of prolapsus uteri with a phosphatic vesical calculus. The patient was 35 years of age, and a cook in domestic service. The uterine prolapse had been known for five years (ten years after the birth of her only child). Formerly she could wear a watch-spring pessary with comfort and relief; latterly, since August, 1893, a pessary had increased the pain. An anterior elytrorraphy and a colpo-perinæorraphy were performed for the relief of the prolapsus; three weeks afterwards the bladder symptoms still persisted; the bladder was examined and a phosphate calculus of considerable size was found. The calculus was too large for removal per urethram without the risk of permanently damaging the sphincter. A longitudinal incision was made in the vesico-vaginal septum; the calculus was removed through the incision and the bladder drained by a glass tube for twelve days; the septum healed completely and left a fine lunar cicatrix. Dr. Briggs would not advocate incision of the septum in preference to lithotrity in suitable cases; he had not arranged to crush the calculus, because he feared a foreign body was the nucleus of the stone.

Case of Sudden Death in a Child.—Dr. A. C. **Harris** related a case of sudden death in a child, æt. 8 months; (?) Cause. The child was a well-cared for, well-nursed, closely-looked after baby, in fact, had never been ill before. Dr. Harris was sent for because the child had had a crying night and seemed in pain. This was at 10 a.m.; the diagnosis was intestinal irritation, and treatment accordingly. The child died at 6 p.m. There was no choking, cough, or struggle, and the face quite pale. At the post-mortem, fifteen hours after death, *rigor mortis* well-marked, all the thoracic and abdominal organs healthy, the cardiac ventricles in firm systole, the intestines empty, with no ecchymoses, adhesions, &c., a little milk in the stomach.

Dr. **Alexander** read a paper on

PUERPERAL FEVER

based on his experience at the Liverpool Workhouse Hospital, and he quoted the statistics of that institution for twenty-six years, the time represented by all the lying-in registers he could find. During that period 8,323 woman had been confined, of whom 2,685 are entered as married, and 5,638 as single. The mortality from septic influences was ·5 per cent., and from all causes 1·4 per cent. The causes of death were verified generally by post-mortem examination, and sometimes occurred several months after confinement. The causes of death were described in detail, and points of interest briefly alluded to. Dr. Alexander then proceeded to show that the arrangements of Nature at and after confinement, in ordinary cases, were admirably adopted for the healing of the intra-uterine wound aseptically and safely, that puerperal fever was a wound fever and nothing else, that the contagious fevers, such as scarlet fever, had no influence in producing puerperal fever, except the patient at the same time contracted that contagious fever when she would probably suffer from it, and not from puerperal fever. He then described the lying-in wards at the Workhouse, the staff employed there, and the means adopted for the prevention and cure of puerperal fever. He alluded to the statements made by a member of the institution before the Royal Commission in regard to these statistics, and said he had invited the member to attend and make his objections to the statistics before his medical brethren, but he had not replied or attended.

Dr. **Macfie Campbell** considered that a legitimate specialty is a midwifery one, and that the midwifery practitioners should avoid as far as possible attending infective diseases. Dr. Campbell had recently absolutely forbidden nurses to use douches.

Dr. **Briggs** thought, allowing for differences in site, the surgical fevers were typically represented by the puerperal fevers. He held that the traumatism in precipitate labour and in operative midwifery ought to be considered in relation to subsequent asepsis, and here an intra-uterine douche given immediately after the labour secured what many subsequent douches might never accomplish. During the puerperine delay in recognising the symptoms which mark the onset of the most severe cases where nervous symptoms are often prominent frequently led to dissatisfaction with or failure in the treatment. Hence the douche is blamed because it was not given at the proper time.

Dr. T. B. **Grimsdale** said the term puerperal fever, he thought, was too comprehensive; it included a large variety of pathological conditions under one heading, leading to endless confusion. Under the term puerperal sepsis, or puerperal septicæmia, the ground would be cleared and some definite idea arrived at as to what was to be included under the heading. At present puerperal fever might mean any rise of temperature during the lying-in, or it might mean some dread specific disease which, according to some authorities, was peculiar to lying-in women, having origin from scarlet fever, typhus fever, erysipelas, &c., but which, becoming modified in the puerperal woman, gave rise to puerperal fever. All these theories, and many more, would be swept away and the treatment infinitely simplified and made more satisfactory if the term sepsis were used in place of puerperal fever.

Dr. **George Johnston** in his remarks quoted two cases where the puerperal woman had been brought in contact with scarlet fever, in one case with no ill effect, but in the other the woman developed scarlet fever. He thought that puerperal fever was rare in the practice of medical practitioners, but not so in the practice of midwives, and that very few of the midwives were able to recognise the early symptoms, which indicated the need for the douche, and that those responsible for the training of midwives should see that this point was well attended to.

Drs. Hope, Murray, and Macalister also made remarks.

[FROM OUR OWN CORRESPONDENT.]

Paris, April 21st.

Rupture of the Kidney.

At the Société de Chirurgie M. Marchant, referring to a case of rupture of the kidney treated by expectation, and mentioned at the preceding meeting by M. Tuffier, said that no doubt there are a large number of cases of contusion of the renal organ necessitating no intervention, but there are others of extreme gravity where there are good reasons to suspect internal hæmorrhage, and an operation must be resorted to in order to save the life of the patient. Further, the operation should be done as soon as possible, as the danger of peri-renal hæmorrhage is very great. An incision is made in the lumbar region, the clots cleared out and the kidney exposed. If there be found but a single rent the parts can be sutured, but if the organ be completely divided, as often happens, nephrectomy is imperative.

M. Lucas considered that the operation is a very safe one; he had treated recently a case of rupture of the kidney by the method described by his learned colleague, and the patient made a very good recovery.

Calculi of the Urethra.

M. Bazy read a paper on two cases of calculus in the urethra. The first was that of a peasant who had suffered from renal colic fourteen years previously. About three years ago he noticed a swelling in the perineal region, but as the tumour did not inconvenience him he would not allow any interference. However, a few weeks ago, the parts ulcerated, and a calculus about the size of a hen's egg was easily removed. The second case was that of an old man who for many years experienced considerable difficulty in micturating, and was supposed by his medical attendant to be suffering from stricture. One day he discovered a small fluctuating tumour in the perineum, and retention having come on suddenly, he passed with some difficulty a catheter of very small calibre. The following day the tumour was incised and some pus flowed out, followed by a stone of the size of a bean; the urethra was destroyed to the extent of an inch. The origin of the stone must be attributed to a renal colic from which the patient said he had suffered from about thirty years previously. The origin in any case, said M. Bazy, of calculi of the urethra is very obscure, but one fact is evident, many derive from the kidney and are arrested in the canal. Before now the operation of lithotrity left frequently fragments in the canal which became the nucleus of urethral calculi; but since the method of Bigelow has been followed no such accidents can occur.

Splenectomy.

M. Terrier spoke on a case of ablation of the spleen, reported by one of his colleagues. A young girl of eighteen was suddenly seized with vomiting, severe abdominal pains, and other symptoms indicating peritonitis. Born in a southern climate, the patient had suffered frequently from intermittent fever. The left side of the abdomen was particularly sensitive, and the spleen was very voluminous. The state of the patient rendered laparotomy imperative. When the abdomen was opened the omentum was found to be adherent and a good quantity of blood flowed out; the spleen was twisted twice on its pedicle and adherent to the neighbouring organs. The operator (M. Hartmann) tied the pedicle and removed the spleen, closing the abdominal wound without washing out the peritoneum. The patient made a rapid recovery, and microscopical examination of the blood some time after the operation showed that the red corpuscles had considerably increased.

In concluding, M. Terrier said that he wished to draw attention to the accidents to which torsion of the spleen can give rise to. He had found two similar cases to that he had just mentioned where the operative treatment saved the patient, while in another case, that reported by a surgeon of Anvers, no intervention was made and the patient succumbed.

Germany.

[FROM OUR OWN CORRESPONDENT.]

Berlin, April 20th.

Thrombosis after Influenza.

Prof. Leyden showed a young man, æt. 20, who suffered from thrombosis. Six weeks before the attack he was confined to bed with influenza which gradually seemed to improve till one morning he awoke with a stabbing pain in the left hand. At this time the hand became pale, and a few days later assumed a dark blue colour. From this time a feeling of cold was experienced in the part, with gradually increasing weakness. When he was received into hospital, no pulse could be found in the left radial artery, but higher up, in the brachial, above the elbow, a feather-like hard thrombus, about three inches long, could be felt in the artery, and on slight pressure, gave great pain. Above the thrombus the pulsation could be distinctly felt. The heart was normal, and no other symptom pointed to the formation of a thrombus except the influenza. The electric testing proof of the muscles of the hand and forearm exhibited great reduction in the response to stimuli. Later several of the muscles became atrophic with regenerative reaction. Measurement of temperature of the skin in the spatium interossei gave for the left hand, 28·5° C., for the right hand, 34·8° C. The thrombus extended upwards 15 centimetres above the internal condyle. Gradually, however, the symptoms improved, the circulation was slightly restored, although pulsation at the radial artery was never obtained.

Spontaneous arterial thrombosis and gangrene are not unknown after acute diseases, and more particularly in the convalescence of typhus. We have also a case of closure of the arteria poplitea after erysipelas recorded by a French observer, and again after a case of influenza. The presence of arterial thrombosis after infectious diseases, especially influenza, can be easily understood where a marasmatic influence is present; but Leyden is inclined to believe from the recovery of the patient after the influenza that the marasmatic influence is passed, and that the phenomenon inducing the thrombosis was the destruction of the white corpuscular element of the blood which from the beginning of the disease to the height of the fever and even after this period would be greatly reduced. He quoted from different experiments the effects of toxines on the white corpuscles and the great accumulation of blood discs coagulating in the arteries.

Laache said that the puerperal condition was credited with peripheral thrombosis, but from a clinical standpoint he thought there was less peripheral thrombosis in this than many other diseases, such for instance as influenza, six cases of which he had to record, and might be properly termed "grippal thrombosis." He confessed that early epidemics of this disease were not so fraught with thrombosis as the later appearance of the disease seems to have been. Whether the latter be the genuine epidemic, he is unable to say, but the character of the disease has evidently changed. Of the different diseases, typhoid, pneumonia, rheumatism, chlorosis, and senile decay, he has only seen fourteen cases, three of which were males, and in all thrombi were confined to the vena femoralis, saphena major or minor.

Diseases of the Heart in Typhoid, Scarlatina, and Diphtheria.

Rhomberg, in publishing his investigations, points out that the parenchymatous and interstitial processes are not so closely connected in the tissues of the heart. In typhoid the higher grade of parenchymatous degeneration advances rapidly to the end of the second week; but later this morbid change is not so great. Interstitial myocarditis, on the other hand, only makes its appearance at the end of the second week, when the parenchymatous has run its course. In scarlet fever the interstitial myocarditis may begin to make its appearance on the fourth day, but its intensity is not reached till the end of the second week. Diphtheritic myocarditis makes its appearance later than scarlet fever, usually about the seventh or ninth day, and its intensity is reached about the beginning of the third week, and is continued even into convalescence. Rhomberg has seen myocarditic bands from diphtheria in the third week. Leyden has recorded several in the fourth week well advanced. In typhoid Rhomberg has met with these in the third week. The symptoms during the fever period are—great weakness of heart, irregularity and smallness of the pulse, probably with dilatation. The best sign of dilatation of the left ventricle with irregular contractions is, according to Leyden, galopprhythmus. Traube considered sudden sinking of the pulse "frequenz" an ominous signal in diphtheria. Leibermeister considered the pathological increase of tissue fluid, as œdema of the ankles, a dangerous symptom. Dilatation is frequently met with in typhus by the middle of the second week observable by the soft and empty pulse. In diphtheria Rhomberg can only relate one case of dilatation occurring in the first week in diphtheria. On the other hand, he has found it after a few days in scarlet fever continuing two or four weeks.

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, April 20th.

Ectropia Cordis Congenita.

R. v. Braun showed an infant, 36 hours old, weighing 2,600 grammes, and healthy in appearance with the exception of the ectropia. In the anterior wall of the thorax there is an opening somewhat smaller than the size of the heart, but it is presumed that the heart developed and long existed outside the body before retraction; probably there existed a band of amniotic tissue passing from the anterior to the outer coverings. There was also on the right side of the head a large necrotic patch; the sternum was quite absent. The heart was twisted about 90 degrees from the normal, the right ventricle anteriorly, and the left posteriorly. It appeared suspended by the vessels; the pulse was slow, and the vibration of the heart wide during the systole. It was a surprise to all that the child had lived so long. The opening is covered with a flap of lint moistened with common salt.

Dr. Reiner remarked that he had often met with such cases in young animals, and that the heart when contracted became very red, as was observed in the present case, which showed that the superficial layers of the heart became greatly hyperæmic in systole.

Polypus.

Rethi showed a man, æt. 53, who had consulted him with troublesome cough, difficulty in breathing, but the voice was perfectly clear. The laryngoscope revealed a polypus the size of a hazel nut in the posterior wall of the larynx whose anterior pole presented into the trachea. It was removed by galvano-caustic snare and found to be an œdematous fibroma with its surface covered with flat epithelial cells.

Testicle Enlargement.

Wick brought forward a young man who, after a severe illness, was affected with enlargement of the left testicle. Fever was absent. After this the trunk was affected with small pus vesicles appearing on the extremities and joints. Later the testicle was found to present a circumscribed fluctuating point from which pus was drawn and found to contain tubercular bacilli. He considered this to be an undoubted case of inflammatory tubercular testes with metastasis on the surface of the body.

Warm Baths.

Wick read a paper on the effects of warm baths on the temperature. He said the specific heat of the body was reduced when the bath was between 31° and 34°, but the reduction was not parallel with the time or temperature of the bath. The pulse was increased when the temperature of the bath rose to 37°, but was unaffected between 34·8° and 36·4°. The specific heat is increased during the first half hour, but gradually becomes less thereafter. The amount of direct heat depends a good deal on the conductivity of the tissues as proved by experiments on the dead body, which shows that the heating is in the ratio of geometrical progression. The true heating agent in the body is through the circulation.

There are other factors as radiation, conduction, and evaporation which he maintains to be most important, as in breathing, perspiration, &c. The latter is adapted for the packing treatment as the perspiration is abstracted from the blood. All these conditions must be accepted as arbitrary as the body will soon accommodate itself to the treatment by warm baths and fail to act either by evaporation, radiation, or conduction.

It may be approximately stated that the pulse is increased 10 beats per minute by increasing the temperature to 40°, while the skin is greatly reddened.

Another point of investigation was the effect on the metabolism of the body. The body weight begins to sink after commencing the warm water treatment, falling 500 to 350 grammes; after which it begins to increase if treatment be continued till the body has reached 50 to 600 grammes more than it weighed at the commencement. The loss is greatest at the commencement of the treatment, and is more rapid than the increase. The nerve system is in no way irritated by the treatment. The quality of the pulse measured by the sphygmograph shows no weakening of the arteries as is generally assumed, the hæmoglobin is increased; the blood is not subsequently thickened; the leucocytes are increased; the breathing is longer and deeper, and the sensation of the skin is soon restored.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Splenectomy.—Mr. **Pearce Gould** removed the enlarged spleen of a woman, æt. 38, who had been for some time under the observation of one of his colleagues, Dr. Coupland. The spleen reached two inches below the umbilicus and half way between the left linea semilunaris and the linea alba. It was slowly enlarging. There was no leucocytosis and no history of malaria, and very slight anæmia. The case was regarded as one of splenic anæmia in its early stages, and it was believed that removal of the spleen would cut short the disease. Such a result, Mr. Gould pointed out, had been previously obtained, and all other treatment for these cases had been ineffectual, and they terminate fatally. A long incision was made in the left linea semilunaris and the spleen carefully delivered, the lower end first. The pedicle was a broad but exceedingly short one; it was tied with silk in seven ligatures, great care being taken not to wound the pancreas. The peritoneum on each side of the hilus was dissected up a little to make a safe pedicle and the spleen cut away. There was no hæmorrhage from the pedicle. The wound was closed with three rows of silk sutures. Mr. Gould remarked on the advantage of a free incision, so that the spleen could be delivered easily without tearing its capsule; he thought it was very important not to make any traction on the pedicle, as such traction has been known to cause extreme collapse; the pedicle, he said required very careful ligature, and the surgeon had to be very careful not to include any portion of the pancreas, as that accident had been known to cause gangrene of the gland. Hæmorrhage, shock, and injury of the pancreas were in his opinion the chief dangers of the operation.

It is satisfactory to state that at the end of the fourth day the patient was doing well.

Nephrectomy for Intermittent Hydronephrosis.—The same surgeon operated on a woman, æt. 26, who seven years previously had been in the hospital under his care with a dilated left kidney. Whilst under observation the dilatation had suddenly disappeared. Nothing further had been noticed till a few weeks before the present operation, when pain in the loin came on and the tumour again was apparent. The kidney was excised through the loin from within its proper capsule, the capsule being peeled off. The vessels were included in one ligature and the ureter in another. Buried sutures were placed in the divided muscles and the skin wound closed, no drainage being employed. The kidney was found to be greatly dilated with an enlarged pelvis opening abruptly into a narrow ureter.

KING'S COLLEGE HOSPITAL.

Thyroidectomy.—Mr. Carless operated on a woman, æt. 32, the subject of a small but troublesome goître. A few years back she had come under his treatment for constitutional syphilis, the primary sore having apparently formed upon the gum of the upper jaw. It was followed by an ulcerated throat, and a small opening in the hard palate had developed subsequently. The enlargement of the thyroid body had been noticed a little over a twelvemonth, and had recently caused a good deal of respiratory embarrassment, especially at night. An incision was made along the anterior border of the lower half of the right sterno-mastoid muscle, which was exposed and drawn outwards. The omo-hyoid muscle was separated and retracted upwards, the sterno-hyoid and thyroid muscles partly divided and drawn well over towards the middle line. The capsule of the tumour was now clearly exposed, and the surrounding tissues freed by manipulation from the right lobe. The vessels entering and leaving the mass were now dealt with and ligatured, the superior thyroid vessels being secured at the upper angle, the middle thyroid vein at the centre of the outer margin, and the inferior thyroid vessels below. The tumour was now freed from all its connections except the isthmus, great care being exercised to keep as close to the capsule as possible so as to avoid injury to the recurrent laryngeal nerve and subjacent deep vessels of the neck. The isthmus was transfixed well on the left side and ligatured by means of silk which had been previously boiled in carbolic lotion (1 in 20). The deeper parts of the wound were approximated by buried stitches, and the skin closed by a continuous catgut suture. A drainage tube was inserted, but Mr. Carless stated that it would be removed in 24 hours. He also commented on the exceedingly satisfactory nature of this operation in removing the general symptoms of palpitation and irregular heart's action associated with the excessive absorption of thyroid secretion, and mentioned a case in which he had recently operated with the most gratifying results.

ST. MARY'S HOSPITAL.

Tuberculous Cervical Glands.—Mr. Owen operated on a little girl of about six years, the left side of whose neck was bulging with what he described as tuberculous glands. He said that he had never operated on a worse case; both the anterior and the posterior triangle was full of them. Fortunately, however, they were not suppurating. Beginning with the posterior group, he made an incision along the posterior border of the sterno-mastoid, and removed an enormous quantity, some of them being taken from under cover of the mastoid process, and some from behind the clavicle. He remarked that in removing the lowest of them his finger was touching the subclavian artery. Then with a free incision in front of the sterno-mastoid he cleared the anterior triangle. During the operation he called attention to the spinal-accessory nerve and to several inches of the internal jugular vein, which was naked and bulging. A drainage tube was passed beneath the sterno-mastoid and out by the posterior wound. The wounds were closed with silk suture and dressed with wood wool; (fifty-eight separate clusters of removed glands were counted). Mr. Owen remarked that when the internal jugular vein was pulled up with a mass of glands it became stretched, flattened, and emptied. It thus looked exactly like an innocent band of connective tissue, and was liable to be injured. The safest thing then to do was to press the finger upon the opening, and, having isolated the vein and tied it above and below, to cut it across. The operator called attention to the fact that in many surgical text-books it was stated that when a surgeon was about to tie an artery in its continuity he must be careful to make only a small opening in the sheath of the vessels, lest the vasa vasorum being severed, the arterial coats should slough and secondary hæmorrhage occur. If this teaching were founded on fact, it should be equally applicable to the vein. But, as a matter of fact, the large vein showed itself to be very tolerant of denudation. In many cases where, during the operation of removing masses of diseased glands from the neck, he had been compelled to lay bare several inches of the internal jugular, he had never encountered secondary hæmorrhage. He thought that there was a fallacy in connection with the vasa vasorum theory; it had probably found origin in the fact that the surgeon or physiologist who first suggested it was surrounded by sepsis and suppuration. Years ago, secondary hæmorrhage was of frequent occurrence after operation, but asepticism had almost completely banished it.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, APRIL 25, 1894.

HOSPITAL ABUSE.

A correspondent of one of our medical contemporaries, who signs himself "S.," has evoked the wrath and indignation of a host of practitioners by a defence of the hospital out-patient system, which is daily diverting from the pockets of practitioners the fees which constitute their legitimate means of livelihood. Stated briefly, his defence of the system is twofold: 1. That "a considerable number of persons need—not merely would like, but really require—better advice than they can get for the fees they can afford to pay;" and, 2. That "the physician must live . . . . a practical contact with crowds of patients he must get somehow if he is to become . . a skilled physician." These phrases state mildly the motive power of the abuses of hospital charity. It goes without saying that three-fourths of the world will abstain from paying for an article which they can get of as good quality for nothing; it may also be taken for granted that every aspiring doctor or other professional man will adopt any or every means which is not absolutely disgraceful to get on in the world without regard to whose body he walks over. Until General Booth's reconstruction of the morality of the Universe comes off, these principles may be taken as immutable and universal, and it is, therefore, utter waste of time to objurgate against patients for being mean, and against doctors for being selfish, especially as no possible code of laws or morality could be constructed or enforced which could cure either party of its inborn sin. Whence, then, is the remedy for the disgraceful abuse of hospital charity to come? Surely from the influence of those people whose money is misappropriated and whose benevolent intentions are frustrated by the abuse of the hospital system. There is no more instructive illustration of the prevalent belief that the wealthy public are "mostly fools" than the audacity with which hospital managers proceed to waste thousands of pounds and continue to do so until a monstrous debt has accumulated, in perfect confidence that, when the obligation can no longer be staved off, any number of thoughtless but wealthy people will be found ready to pay it off and restore the opportunity for further extravagance and waste; and it seems that the hospital managers are sensible men of business, having tested their confidence in the stupidity of the public by ten thousand preceding experiments upon the gullibility of the moneyed benevolent. There is, in our opinion, no hope of a remedy for hospital abuse as long as these so-called charitable people are ready to part with their money in handfuls without bestowing a thought on the merits of the charity for which the money is asked, and therefore we think that the only chance of stemming the ever-increasing tide of idiotic hospital benevolence is to spend time, labour, and some money in instructing and educating these people. We know that there will always be many in this, as in other matters, whom no instruction or education will ever prevent throwing their money away in this manner, and the money of these can always be calculated upon by the sponges of hospital administration; but we are confident that, speaking generally, if the grateful old lady who hands her physician a cheque for £1,000 for his hospital, or the obese and moribund millionare who leaves ten times that amount to some such institution in his will, only knew that three-fourths of their benefactions were going to be wasted upon well-to-do but unutterably mean patients, or for the advertisement of ambitious doctors, they would certainly not loosen their purse-strings. If, for instance, they were told that one London suburban hospital expended at the rate of £261 15s. 3d. per bed occupied, or £14 16s. 3d. for every patient it took in—if they knew that, in the case of a large number of hospitals it would be as cheap to take the patients out and pay for them as guests at the best hotel in the neighbourhood. It is almost impossible to believe that they would continue to throw their money away on such institutions. Here, then, is the remedy for all hospital abuses. Let a small society be formed which shall expend a small annual revenue in circulating such facts as this by handbills and publishing them by advertisement. Such a society would be assailed, as the Charity Organisation Society has been, by the large and influential section of the public who are interested in the continuance of hospital abuses, and it would be said that the society was damming up the flow of public benevolence. That is exactly what it is desired to do, in the case of wasting hospitals and institutions for the gratuitous relief of out-patient sponges. It is our well-matured opinion that if, in many cases, hospitals were much poorer than they are, they would be much better, their administration more business-like and economical, the surgery and medicine dispensed by them not a whit the worse, and the patients accommodated, not less numerous, though much more honest and select.

THE SMOKE PROBLEM.

The smoke nuisance is undoubtedly one of the great drawbacks of latter day civilisation, and how to deal with it satisfactorily in our large towns has puzzled and is still puzzling the inventors of many countries. That it is damaging to clothes, furniture, and many household belongings, that it causes fogs, and that it is disastrous in its effects on life, both animal and vegetable, are propositions so widely established as to require nothing more than passing mention. It is equally to the front in Birmingham, the busy hardware capital of the Midlands, with its thousands of smoke-vomiting factories, and in London, where the nuisance is chiefly traceable to a million and a half house-chimneys. Statistics often cast vivid side-lights upon familiar subjects, and there is a startling weird suggestiveness, even to those accustomed to the ample nature of metropolitan statistics, in the statement that forty thousand tons of coal are burned every winter's day beneath the house chimneys of greater London. The chief remedies hitherto suggested for the solution of the smoke problem were thus summed up last year in the House of Lords by Lord Salisbury:—"(1) The use of anthracite, which kindles slowly, and is, therefore, like coke for the same reason, very unpopular; (2) The use of gas, the price of which is prohibitive to the poor, whose chimneys alone vomit daily some thirty-five tons of sulphur into the atmosphere; and (3) The invention of an improved grate that would consume its own smoke." Of these three recommendations, the last appears to be the most promising, that is to say, so long as we depend on coal as the main source of artificial heat. It is in the direction of improved grates, indeed, that the attention of inventors has hitherto been chiefly engaged. As a result we find a great number of slow-combustion and smokeless stoves and grates upon the market. None of these contrivances, however, have ever become popular, that is to say, in any wide sense of the term. The good old English open fireplace, with its air of comfort and its woeful lack of scientific principle, still reigns supreme.

In America, where the science of warming buildings is in a more advanced stage than with us, the houses are supplied throughout with warm air, the regulation of which is under perfect control. While it is possible that human ingenuity may one day solve the problem of how to use coal and avoid its present disadvantages, yet sooner or later the day must come when there will be no more of that useful modification of carbon left for us to utilise and grumble at. However, it is likely that long before our coal-fields are exhausted electrical science will in some way or other supply us with an alternative substitute for present methods. Already electric lighting has secured a firm foothold, and is ousting our gas-burners from their monopoly by leaps and bounds. But in the meantime, any generally available plan of artificial heating, apart from the combustion of coal or its products, is practically unknown: so that, for a time at least, town dwellers must be content to endure the evils of a smoke-polluted atmosphere. That the injury to the national health is considerable is a proposition that hardly requires formal proof. The same injurious products that destroy plant life must be harmful also to that of man. Soot, by its mechanical and sulphurous acid, by its chemical qualities, cannot fail to be damaging to the delicate tissues of the human lung. The actual amount of injury and loss sustained by the community from smoke-products cannot, for obvious reasons, be even approximately ascertained. It may be confidently asserted, nevertheless, that the national loss on this score must amount every year to an enormous aggregate. The discovery of improved methods of regulating and rendering harmless the combustion of ordinary coal for heating purposes will therefore be a great gain to the science of preventive medicine. But a greater and more radical step towards obtaining an ideal atmosphere will be made when some other source of artificial heat is brought practically within the grasp of the householder and the manufacturer. The chief argument in favour of subsidising science is that its discoveries, by fostering and developing native industries, quickly repay expenditure. In the same way a Government vote even of millions of money, if devoted to the subject of alternative methods of heat-production, could hardly fail to effect in the long run an enormous saving to the wealth not less than the health of this great country.

◆

THE GROWTH OF POST-GRADUATE TEACHING IN LONDON.

A sign of the times is certainly that afforded by the remarkable development of the facilities provided for post-graduate teaching in London. A few years ago there was no such thing as any systematic course of the kind; foreigners and colonial *confrères*, together with medical men practising in these islands who were desirous of improving their stock of professional knowledge, were in the habit of visiting London, and were compelled to go "empty away," on account of the complete dearth of any regular facilities by which they could add to their medical education. This state of things was a reproach to London, with its vast, almost unlimited, supply of clinical material collected in the various hospitals, special and general, and in the union infirmaries. Foreign medical men, coming direct from the splendid *cliniques* on the Continent, could never understand how it was that London was so backward in this respect. Attracted by the reputation of distinguished English physicians or surgeons, foreign *confrères* would come to London, fully expecting to find systematic teaching in vogue similarly to that to which they had been accustomed in their own country. But grievous disappointment must in many cases have awaited them. The "custom of the country" is not to organise large *cliniques* with distinguished men presiding over them. The more famous an English surgeon or physician becomes, the less does he teach. Teaching in the centres of medical education is merely regarded in the light of a stepping-stone to practice. No sooner is the pedestal of a lucrative practice mounted than the stepping-stone by which the ascent was made is ignored, and others are left to make use of it as best they may. The answer, of course, is that large consulting practices scarcely allow any time for the successful possessors of them to undertake teaching appointments. The real teaching in the various medical schools throughout the country is almost entirely in the hands of the young *alumni* of the hospitals. Upon the young assistant surgeons and assistant physicians mainly falls the burden of educating the succeeding generations of medical students. The senior members of the staff practically contribute only a small proportionate share to the teaching provided, and the exigencies of time and the calls of practice render any other arrangement than this almost impossible. Anything, however, which will tend to deprive London of the reproach so frequently urged against it, of having no organised teaching, should be regarded with satisfaction, and in this connection, it is gratifying to note how great has been the progress in the organisation of post-graduate lectures in the metropolis within recent years. The first definite step in this direction was made by the staff of Charing Cross Hospital. The scheme proved so unqualified a success that a movement was started to embrace several hospitals: this led to the formation of the London Post-Graduate Course, in which the staffs of nine or more hospitals agreed to take part in the delivery of daily lectures and demonstrations. The latter undertaking, it may be observed also, has proved highly successful; indeed, nothing could testify better to the want which existed in this regard than the popularity which these post-graduate schemes have rapidly acquired. Up to a few months ago no definite attempt had been made to extend the area of post-graduate instruction: that is to say, beyond the London Post-Graduate Course, and that at Charing Cross Hospital, medical men desirous of joining classes of the kind had only these from which to choose. In the near future, however, it is quite possible that the staffs of most of the smaller general hospitals in London will have organised courses designed for post-graduate teaching. In this connection already two may be mentioned as having led the way, namely, the West London Hospital, Hammersmith, and the Metropolitan Hospital, Kingsland Road, N.E. The utility of this movement appears to be that for a small fee the practitioners in the neighbourhood of the smaller general hospitals will have a good opportunity of seeing valuable cases and of adding to their stock of professional knowledge with the least amount of trouble to themselves. This is, of course, altogether apart from any foreign members of the profession, to whom the convenience of joining the courses might in particular cases become apparent. Upon the whole, we feel constrained to express our satisfaction that a real awakening appears to be taking place in this regard on the part of the staffs of non-teaching hospitals, and that the fact has at last been recognised that, although the medical students are absent in the latter institutions, there is no reason why the resources of the wards and out-patient rooms should be lost to the profession. The enterprise of the staffs above mentioned has our entire concurrence, and we should be glad, as has already been remarked, to see the movement carried out to its fullest extent.

◆

Notes on Current Topics.

The Registration of Male Syphilitics.

The repeal of the Contagious Diseases Act in this country, in deference to the persistent outcry of agitators, has resulted in the dissemination of a great deal of what otherwise would have been preventible venereal disease. But quite recently a new light has been thrown upon this subject by a suggestion which comes from America, that prostitution should be controlled by an Act rendering compulsory the registration of male syphilitics. The basis of the suggestion appears to be some facts to which attention may here be drawn. It would seem that in 1867 the Russian Government opened for its own Navy some brothels at Nazaski, for the exclusive use of the sailors. The Japanese girls were carefully examined, and when found healthy were placed "on trade" for the use of the Russian marines However, even such precautions as these did not prevent the prevalence of venereal disease. It was found that the officers of the Navy were the means by which the infection was transmitted, and not the women; the former had contracted it in Calcutta, Singapore, and other Indian ports, and thus the women became infected and the disease was propagated. The idea of preventing infected males from becoming the medium of disseminating syphilis is certainly a novel one; there is undeniably something which can be said in its favour. But in what manner could such preventive measures be carried out? Under what system could men be submitted to examination whenever they were visitors at brothels? Presumably to each brothel a medical man would have to be attached in whom would be invested the power of examining each male visitor who presented himself, and the subsequent course of events would entirely depend upon the results of the examination. In discussing, however, the details of this suggestion, it is obvious that difficulties present themselves at every turn which appear to be insuperable. It must, of course, from time to time happen that the prostitutes of the town are infected by the men whom they receive, and it must, therefore, naturally follow that if some means could be devised for detecting and registering the male syphilitic much good would result. But how could this plan of registration be carried out? That is the problem.

The Medical Defence Union.

A number of members of the Medical Defence Union met on the 18th April in the rooms of the Medico-Chirurgical Society of London. The meeting, which was non-official, had been called together to hear a personal statement by Dr. Leslie Phillips as to the causes which led to his resignation of the secretaryship, and also to consider the position of the company generally. The chair was taken by Dr. Norman Kerr. Dr. Phillips entered into a full explanation, and several speakers addressed the meeting. In the absence of the President and members of Council nothing of the nature of a personal attack upon them was very properly permitted. Out of the large number of members present 102 signed the following requisition to the Council:—"We, the undersigned, being upwards of twenty members of the Medical Defence Union, Limited, do hereby, in pursuance of the 17th Article of Association, request you to convene a special meeting of the members of the Union to be held on such day (not being later than 21 days after the 19th April, 1894) and at such hour and place in London as you may deem most convenient, for the following purposes, viz:—(*a*) To consider the recent action of the Council of the Union, in connection with the litigation between Drs. Collie and Bloxham. (*b*) To consider, and if thought fit, to repeal the present Articles of Association of the Union, or some of them, and to substitute others therefor by special resolution with the object of preventing the Council or governing body of the Union in future interfering in disputes of a purely private or domestic nature between members of the Union, or between a member of the Union and any other member of the medical profession not being a member of the Union." Another resolution, moved by Dr. H. H. Sturge, was carried unanimously. It was to the following effect:—"This meeting feels the deepest regret at the resignation of Dr. Phillips, and in view of his proved experience and foresight trusts the loss of Dr. Phillips to the executive may only be temporary."

Medical Evidence in Criminal Cases.

In a murder case which was tried last week in Dublin, a medical practitioner got himself into serious trouble and was fined £5 for contempt of court for refusing to attend upon his subpœna. Apparently his testimony was required for the defence and for the purpose of showing that the deceased might have died from other causes than injury, and, as to this, the doctor said that he knew next to nothing of the matter. What we are concerned about is as to the obligation on him to attend without security for his fee. The law on this subject is obscure and unsatisfactory. If the subpœna was issued from the Crown Office, whether the evidence was for the prosecution or the defence, the doctor should have attended, and his fee, according to the fixed scale, would have been secure to him. We believe that, as a matter of fact, the *contretemps* arose from the fact that he thought that the summons came from the defendant, and that, if he attended, he had little chance of being paid, and he derived this impression from the fact that the document was not served by the police, but by an attorney's clerk. He was wrong in this impression, and was fined accordingly; but, suppose he had been right, the question is whether a doctor is compelled to attend and give expert evidence in a criminal case upon a subpœna couched in the usual official form but issued by the defendant and without payment of fee. We know that, in a civil suit, the subpœna technically binds the witness to attend and give evidence as to matter of fact, like any other citizen, but that if he abstains from attending because his expert fee is not paid or secured to him, the judge will very rarely enforce the subpœna. As we believe, this remark does not apply to criminal cases, and that if a doctor is served either for prosecution or defence in such a case, he must be present and will probably get his fee from the Crown if the defendant is not able to pay it.

Medical Students from South Africa.

A South African contemporary draws attention with pride to the successes of the medical students from the Cape at the last examinations of the University of Edinburgh. The "Cape men," as they are commonly called by their fellow-students, have certainly distinguished themselves, as a reference to the honours list will show. For example, one Cape student carried off the silver medal of the School of Medicine; another secured the gold medal in anatomy at the Royal College of Surgeons, Edinburgh—the "blue ribbon" for third years' men; yet another student gained the medal for second years' men; while the bronze medal in pathology and that in practical and microscopical pathology also respectively fell to students from South Africa. When it is remembered that the South African students are hardly three per cent. of the total number in the Faculty of Medicine, these successes appear to us all the more striking. In any case, however it speaks well for the attractions of the Edinburgh School that so definite a proportion of Cape students seek their medical education in the northern capital of the kingdom, and avoid London. The deficiencies of the educational system, mainly represented by the absence of a university which would give London students access to degrees in their faculty, must be held to be chiefly responsible for this state of things. It is generally admitted that the clinical material in London available for teaching purposes is superior by a long way to that which any other teaching centre can show throughout the world. Yet, despite this fact, medical students are fast becoming accustomed to turn elsewhere for their medical education.

The Birmingham Board of Guardians.

It seems that the small-pox epidemic in Birmingham shows no signs of material abatement. The Birmingham Guardians have had the matter under their serious consideration. It appears that the Board has allowed the Health Committee of the town to house their small-pox cases in a stone-yard adjoining the workhouse infirmary, pending the erection of a new small-pox hospital at Yardley. The Health Committee was to have resigned their occupation of the stone-yards by December 31st, and an extension of that time to March 25th was reluctantly granted by the guardians. The request of the Committee for further use of the yards was acceded to. Several interesting points were brought out during the prolonged discussion which took place. For instance, fourteen cases of small-pox occurred in the workhouse infirmary, five of which could be traced to one centre. These figures prove that small-pox sheds were very far from being an active source of infection to the infirmary. Moreover, it is almost certain that the disease would be sooner or later brought into the wards from infected districts. Another interesting fact is that in the face of an urgent epidemic the Health Committee accepted a contract for the erection of a special hospital within twelve months. Rapidity of action is everything in these cases. Instead of expensive permanent buildings, the principle has long since been generally accepted that it is best to treat small-pox in temporary sheds. One speaker went so far as to say that such mismanagement could have happened only in "the best-managed city in the world," as Birmingham has been fondly styled.

Chelsea Hospital Scandal.

It has been decided to re-organise the committee of inquiry appointed to consider the charges brought by Dr. Louis Parkes against the Chelsea Hospital for Women. The Chairman, Lord Cadogan, has addressed to the Chairman of the Chelsea Vestry an explanatory letter, from which we quote the following:—"I beg to inform you that I have received an intimation that the consulting medical and surgical staff of the Chelsea Hospital for Women, who have been invited to become members of the proposed committee of inquiry, have declined to join the committee. In view, therefore, of the letter addressed to me by the clerk to the vestry, stating that the vestry are of opinion that the professional members of the committee shall be limited to members appointed by the Royal College of Physicians and Surgeons, I venture to hope that, inasmuch as the views of the vestry in this respect will now be carried out, members will be willing to appoint forthwith one of their body to serve upon such committee of inquiry. I may add that the Presidents of the Royal Colleges of Physicians and Surgeons have now agreed to depute a member of each of those bodies to represent them, and that Lord Sandhurst, Lord Balfour of Burleigh, and Sir Chas. Dilke have also agreed to serve." It will be seen that the composition of the committee is broad and responsible, a fact which will tend to satisfy both the public and the medical profession that the inquiry will be thorough and trustworthy.

The Pail-Closet System.

The evils of the pail-closet system, to which the town of Leicester appears to be particularly exposed, were forcibly pointed out in a paper read by the Medical Officer of Health for the borough at a meeting last week of the Midland Branch of the Society of Medical Officers of Health. In referring to the typhoid history of the borough for last year, the author pointed out that the existence of the antiquated system had a close connection with the prevalence and dissemination of the fever. Out of a total of 406 cases he had no difficulty in tracing 108, or 26·6 per cent., to pre-existing cases. Moreover, while investigating some of these direct infectious cases, he was struck with the proportionately large number of infected houses which were supplied with pails as against those provided with water-closets, and the proportion of typhoid-infected persons in houses in the former as compared with those where the sanitary arrangements were better was three to one. This is a serious indictment against the use of pail-closets and the sanitary committee of the town should lose no time in getting rid of this serious sanitary defect. It appears that there are still 7,000 of these malodorous appliances in Leicester, whose presence will always be a menace to the public health. Clearly, therefore, with the sewerage system which is already available, the alterations from pail-closets to water-closets should at once be proceeded with throughout the town. Something has already been done in this direction, but the work appears to be progressing very leisurely.

A Fever Hospital Patient Fined.

The public is generally assured that when a patient suffering from fever is placed in a fever hospital that one centre of infection, at any rate, is removed from their midst. From a recent occurrence at Bristol, however, it appears that there is a further factor to be taken into consideration, namely, the personal element in individual patients, before isolation can be regarded as quite secure. In the instance to which we refer a youth, who hailed from Cheltenham, but was an inmate of the British Fever Hospital, strolled out to a public-house, and then returned to the hospital, after a short walk through some of the neighbouring streets. For this offence he was summoned before the magistrates and fined 40s. and costs. We are not told whether it was the irksomeness of hospital life that drove this enterprising young man into the streets. It certainly does not look as if the discipline could be very strict in an institution where a patient was allowed to casually leave the place in broad daylight. It is to be hoped that the medical evidence fully proved that the patient's mental condition had not suffered from his illness.

The "Parke" Memorial Statue.

The Committee which has had in hand the organisation of the memorial to Dr. Parke, Surgeon of the Emin Expedition to Central Africa, met last week for the purpose of inspecting designs for the proposed statue. The commission for the work has been given to Mr. Percy Wood, of Queen Anne Street, London, and he has prepared for submission to the Committee two designs, one in military dress, and the other in the costume of African exploration. The unanimous feeling of the committee was that the latter design, being specially appropriate to the work in which Dr. Parke chiefly distinguished himself, and being also capable of much freer and more artistic treatment than the buttoned-up military costume to which most military statues are condemned, should be adopted. The pose represents Dr. Parke standing with one foot raised upon a rock and with a rifle in front, the loose shirt showing chest and arms, and is simple, artistic, and light. The statue will be of colossal proportions, and in bronze, and in order to identify it with Dr. Parke's medical heroism, the pedestal will display, not only a descriptive inscription but a bass-relief of Parke at his professional work on some striking occasion during the expedition. Mr. Herbert Malley, of 14 Kildare Street, Dublin, has charge of the movement as secretary, and will be glad to afford any information desired.

Obesity.

The present year in some respects is a phenomenal one; we have already had a foretaste of summer, despite the fact that spring has hardly commenced. But no one could have predicted that the "silly season" would have "burst into flower" at least three months or more before it is due. Still, this is the fact, which anyone can verify by referring to the columns of a morning contemporary. Of course it is too early yet for the big gooseberry, or the sea-serpent, and a warm temperature is generally considered to be necessary before discussions on matrimony can prove to be successful. But a subject has been discovered which the promoters evidently thought was highly adapted for the time of year. A discussion has been introduced on "the art of losing fat," and already it has swelled to gigantic proportions. In common with former enterprises of the kind, a contribution appeared, more or less sensible, but giving prominence to points obviously designed for the purpose of exciting controversy, and then came a letter from a medical man, signed in full name, affording an opportunity too good to be lost for a gratuitous advertisement. Afterwards followed the rank and file of the persons whose contributions to the "silly season's" discussions are indispensable to its progress. Perhaps, however, no previous discussion of the kind has been provocative of so many inane platitudes, feeble attempts at wit, and silly remarks as that which was just the rage. It may be hoped that our contemporary does not number many cynical persons among its readers, otherwise the perusal by them of the correspondence would be almost certain to make them require medical attendance.

A peculiar case of poisoning is recorded from Leamington in which a chemist died from tin poisoning. He had inadvertently filled his pepper-castor with putty powder, which is impure oxide of tin, and had continued to use it until he fell ill a couple of months afterwards, and ultimately died.

Provident Medical Societies.

At the recent annual meeting of the Worcester Dispensary and Provident Medical Institution an important decision was arrived at with regard to the payment of the medical officers of the charity. The chairman announced that the state of the funds was so satisfactory that it was proposed to divide a sum of £80 among the medical officers. It was subsequently remarked by Dr. Read that in somewhat similar institutions in London the medical officers received 95 per cent. of the pence, 5 per cent. went for management, and the rest was made up by subscriptions. To this he added the observation that in their case the medical officers got no more than 66 per cent In this hybrid class of medical benevolence it is impossible to say what would be a fair proportion of income to devote to the payment of services by and for which the institution exists. A provident dispensary is neither flesh, fowl, nor good red herring, that is to say, it is neither a charity nor a trading institute. Medical men will do well to consider their position from all points of view before they lend their active support to this sort of vicarious charity, of which they are made the instruments.

Slaves of Tobacco.

A prolonged discussion upon the tobacco habit has been dragging its somewhat tedious length through the columns of the public press. It is a stock subject, and one which recurs at intervals with all the irregular frequency of our old friends vivisection, the opium traffic, and the big gooseberry. One cannot say that the present outburst of correspondence has thrown much light into the dark by-paths of tobacco-craving. Neither is it likely to induce the devotees of nicotine to cast off their chains through fear of that which is to come, for nothing seems to have been made clearer than the fact that a man may smoke incessantly for scores of years and yet, in spite of his indulgence, pass comfortably into a green old age. A number of remedies have been suggested for those who wish to break off the habit. Among them are medicated lozenges, hypnotism, sea-bathing, and music. So far as we have seen, no one has insisted upon the value of self-denial and self-control in shaking off the habit, when its advantages are outweighed by its drawbacks.

Anti-choleraic Inoculation in India.

According to our contemporary the *Indian Medical Gazette*, anti-choleraic inoculations in India are still being carried out on an extensive sale. M. Haffkine is at present in Calcutta, where already a large number of men, women, and children of all ages have voluntarily come forward to be inoculated. The arrival of M. Haffkine at the various places which he has visited has always resulted in a cordial reception being accorded him. Upon the whole, too, this new preventive method of treating cholera has been well taken up by the profession in India. But, now that the treatment has been fairly extensively tried, it would be interesting to have some facts showing to what extent it has proved efficacious.

Drugs and the Budget.

The additional sixpence per gallon of spirit imposed by the Chancellor of the Exchequer will have an indirect effect on medical men. As everyone knows, spirits enter largely into the manufacture of tinctures and other pharmaceutical preparations. A proportionate rise may be looked for in the price of those articles into the constitution or preparation of which spirits enter. The following is an extract from the Resolution of the House of Commons: "And the duties of customs on the articles thereinafter mentioned, being articles of which spirits are a part or ingredient shall be proportionately increased, and shall be as follows: Chloral hydrate 1s. 4d. per lb., chloroform 3s. 3d. per lb., collodion £1 6s. 3d. per gallon, ether acetic 1s. 11d. per lb., ether butyric 16s. 5d. per gallon, ether sulphuric £1 7s. 5d. per gallon, iodide of ethyl 14s. 3d. per gallon.

Fees for Duplicate Notification.

A correspondent raises once again the question of the liability of local sanitary authorities for duplicate notification certificates. In his case, a "sixpenny doctor" had been called in first and had duly notified the existence of an infectious disease. The parents on being told the nature of the complaint decided to seek higher, that is to say, more expensive, advice. The "higher advice" man of course notified in his turn, but received an intimation from the local authority that no fees could be paid, the cases having already been notified. Now the law explicitly enjoins on every medical man to notify every case of the scheduled infectious diseases, and any practitioner failing to notify would be liable to the penalties in that case made and provided. Obviously, therefore, it is out of the power of the local authority to contract itself outside of the Act, and we should advise our correspondent to take out a summons to compel payment of the fees due for such notification. As this is indisputably a question involving professional interests, he might solicit the assistance of the Medical Defence Union in obtaining a satisfactory decision.

The School Board and Defective Vision.

The Committee of Representative Managers of London Board Schools have issued their report on defective vision. Among other matters referred to it was pointed out that the gas-lighting was insufficient in many class-rooms, and the suggestion was made that the central light in the rooms be supplemented by gas brackets on the walls. Again attention was drawn to the nature of the exercises in needlework, drawing, and other handwork. Needlework was still the most trying subject as far as the eyesight was concerned. It was, therefore, of great importance that the restrictions in the number of stitches, as suggested by the Code, should be observed. A very practical remark of the Committee was that the "needlework should, as far as possible, be done when the light is brightest." Certain unsatisfactory details were referred to in connection with the "black boards," and it was pointed out that black-boards, even when most advantageously placed, were often almost illegible from distant parts of the class-room. The best arrangement was asserted to be that adopted in the newest schools, where a black-board of ground glass or composition extends along the whole wall opposite the children. Lastly, great stress was laid upon the detection of scholars who needed glasses in order to enable them to work properly and without injury, and the suggestion was made that the sight of each child should be tested on admission by the head teacher for the purpose of discovering defects which might be corrected by being referred without delay to an ophthalmic surgeon at a hospital.

The Barber's "Hair-Clipper."

This comparatively new appliance, so largely employed by barbers, is a veritable medium for the spread of contagious diseases of the scalp. In France epidemics of alopecia areata in regiments have been traced to its use. "There is one thing," says a correspondent in a foreign contemporary, "that can and ought to be done at once, and that is to make it an offence punishable with a fine to use the hair-clipper!" After all, while the razor, the scissors, and comb can be kept comparatively clean, the complexity of the construction of the hair-clipper is bound to render its cleanliness a pure matter of conjecture. Presumably nothing but sterilising it in boiling water would meet the necessities of the case. But where is the barber who would put himself to this trouble for the good of his customers. The only thing to be done, under the circumstances, is to bear in mind the expediency of eschewing the use of the hair-clipper whenever the barber is anxious to apply it in the course of his tonsorial operations.

The Annual Dinner of the Army Medical Staff will be held at the Whitehall Rooms, Hotel Metropole, London, at 7.30 p.m., on Monday, June 18th, 1894, the Director General of the Army Medical Department in the chair. Brigade Surgeon-Lieutent-Colonel J. Hector is the Honorary Secretary of the Committee, to whom all inquiries should be addressed.

The official organ of the British Dental Association is informed that both Mr. E. Lloyd Williams and Mr. W. H. Dolamore have resigned their posts as dental surgeons to Westminster Hospital as a protest against the statement made by Dr. Hebb in his opening address at the commencement of the Winter Session, October, 1893.

We understand that Sir William Stokes has been accorded the distinction of being elected an Honorary President of the International Medical Congress and a President of the Surgical Section.

Mr. Roger P. Goodworth, surgeon, of Winterton Dr. W. W. Stainthorpe, of Saltburn-by-the-Sea, and Mr. Henry E. Brameld, surgeon, of the same place, have been placed on the Commission of the Peace for Lindsey, Lincolnshire, and Saltburn-by-the Sea, for the Northern Division of the County of York respectively.

Dr. Kelly, Medical Officer for Worthing, asks us to state that all reason for the scare of last year has vanished, that there was not one death in the borough last quarter from any notifiable disease, and that the water supply, which is of an exceptionally pure character, is obtained from new tube wells a mile away from the town.

The Royal Pension Fund for Nurses obtained a verdict last week against *The Record Press* for 40s. and costs, with a public apology in the *Times* newspaper, for having slandered the said Association in the columns of the *Nursing Record*

Dr. J. Alfred Masters has been elected a secretary of the Medical Defence Union *vice* Dr. Leslie Phillips resigned, and the offices of the Union have been transferred from Birmingham to 20-21, King William Street, Strand.

The latest telegraphic despatches tend to show that cholera has reappeared along the Russian and Austrian frontiers, and fears are expressed that the threatened outbreak last year is only deferred.

In the House of Commons a Bill to amend the Sale of Food and Drugs Act, 1875, and the Margarine Act, 1887, has been brought in by Sir Charles Cameron, and read for the first time.

We learn with much satisfaction that Mr. Croly, Senior Surgeon of the City of Dublin Hospital, has returned to his residence in Dublin in renewed health.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

Glasgow University Court.—At the last meeting of the Glasgow University Court the Works Committee was authorised to appoint an architect to prepare plans for the buildings at Queen Margaret College with a view to carrying out the purposes of the Bellahouston grant. In consequence also of the further grant of £5,000 for the establishment of a Chair of Geology a committee was appointed to consider and bring up a scheme for the establishment of the chair in question. Professor McKendrick wrote intimating that he desired to hand over to the University the collection of physiological apparatus which he had from time to time added to the laboratory. The Court expressed its thanks for the generous gift.

Hamilton.—A Badly-managed Hospital.—At a recent meeting the Committee of Management met a deputation from the Middle Ward District Committee. The Visiting Committee subsequently reported grave irregularities in the management of the hospital, the matron having alleged that one of the nurses went out at nights and left the patients unattended, and on one occasion encouraged a drunken soldier to come about the place who created a great disturbance. It was stated, on the other hand, that nurses were sometimes turned out of the place in the middle of the night by the matron's husband, and a skilled and faithful nurse had given in her resignation in consequence. It was ultimately agreed to request the matron to send in her resignation, and in the event of her failing to do so within a stated time that a month's notice be given to leave.

Sudden Death of Dr. Cowan.—A painful sensation was caused in Wishaw on the 20th inst. by the very sudden death of Dr. Cowan, Burgh Medical Officer. He was actively engaged in his professional duties up till the night of his death, retiring to bed apparently in his usual health, but was found dead in the morning. An overdose of chloroform is supposed to have been the cause of death. Dr. Cowan was very popular throughout the district, and has been practising in Wishaw for over twelve years.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

IS THE ASSOCIATION OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND A RADICAL BODY?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Allow me to pass over your observation about amateur politicians being consequential, and the implied slur as to their being assertive, especially when their own interests are apparently involved, as being absolutely and totally unfounded.

No doubt the term "Radical" has in many minds come to savour of an ill-odour, but it must be remembered I used the term merely to express the possibly too progressive a policy of the "Association," which may have accounted for many esteemed surgeons having failed to join in its ranks.

But my principal reason for rising at all was to say how much I should have regretted the formation of the new "Society of Fellows" being proposed and carried while quietly ignoring the work done by the "Association" in the past, particularly as the acquired right of biennial meeting of the Fellows was signalised by the chairman so prominently in his opening speech, and this gain was, as I believed, due in the main to the action of the "Association" and its distinguished Vice-President.

If the "Association" numbers its 200 or more members, and the same can be claimed for the new "Society," which also professes itself in favour of reform, the Fellows should form an assembly at their biennial meetings amply equipped for the purpose of advocating useful and judicious reform; this could not be considered the case so long as a large percentage of Fellows stood aloof from the "Association," and I trust one of the advantages accruing to the formation of the newly-formed "Society" will be to counteract the apathy with which Fellows have been charged in all that concerns College politics.

I am, Sir, yours &c.,
James Black, M.B., F.R.C.S.
2 Princes Mansions, S.W.

THE NEW SOCIETY OF FELLOWS OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I attended the meeting held on April 5th, under Mr. Page's presidency, about the formation of the new Society of Fellows of the College of Surgeons of England. My object was chiefly to ascertain, if possible, the views of those who wish to form such a society. I was, of course, aware that if this formation had been determined on no opposition which the members of the existing Association of Fellows could offer would prevent the trial of a rival society; but I thought that a plain statement to the meeting of the objects contemplated by the Fellows' Association—objects which have been partly secured by the perseverance of that body through ten years of arduous struggle—must have elicited from the proposers of the new society some indication whether they adhere to or differ from these objects. I was ably seconded in this effort by Mr. Norton, and the circular issued by the Association had recently reached, I believe, every Fellow in the room. But my expectations were wholly disappointed. No word fell from Mr. Page or his associates to indicate whether they agree or differ with us. The vague and unmeaning words of Mr. Page's circular were supplemented by speeches equally vague. We were told that it was very improper to have any definite opinions or objects, and "quite fie-fie" to take steps for the purpose of getting such opinions supported by votes in Council. We are left, then, to our own interpretation of the language and action of the founders of this society. Fortunately this is very easy. Apart from the questions of detail which crop up from time to time, there are two definite parties among the Fellows—the one which wishes for a new charter by which a larger share in the management of the College shall be given to the general body, and the other which is satisfied with the existing order of things. In order that there might be no mistake as to which side the promoters of the new society belong, we put the views and the claims of the present association prominently before the meeting, and urged those who are in favour of our views to join us. As no reply was vouchsafed either by the chairman or by the other speakers, we can only conclude that they think that the present charter puts the Fellows in their proper position in the College, in which case their society will be an obstacle to all substantial reform. I am not imputing any motives or implying any blame. They may have the most friendly feelings towards us (and I believe many of them really have), but the existence of a society of this kind must necessarily strengthen the obstructive party. I hope, therefore, you will allow me to use your powerful aid in urging on all the Fellows who think with us the necessity of joining the association and promoting the election into the Council of Fellows who will support their views. There is an ambiguous sentence in Mr. Page's circular which appears to insinuate that the association is "a small committee which, without having any truly representative character, might tend to influence, and, in the end, control elections to the Council by methods akin to those of the political caucus of the day." I am very little skilled in "reading between lines" or understanding the meaning of ambiguous hints like this, nor do I see how any small committee could persuade a large body of Fellows to vote for a candidate whom they did not wish to vote for, nor what are the methods which Mr. Page's circular compares to those of a political caucus. The Fellows' Association has always signified in the plainest words possible what its views are, and when it has found candidates who would support those views it has taken the most open and public means for the purpose of promoting their election. It is in no way ashamed of this course, and has not (as far as I know) any intention whatever of abandoning it. It is the only intelligible method of procuring reform; it has had considerable success hitherto, and will, I believe, ultimately succeed in securing the end we have in view. I firmly believe that the Fellows are generally of our opinion, so I hope the new movement may result in increasing our association till it includes a majority of the whole body.

I am, Sir, yours, &c.,
T. Holmes.
Great Cumberland Place, April 11th, 1894.

WHAT CONSTITUTES UNSOUNDNESS OF MIND?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You kindly published a letter from me in your issue of the 11th inst. in reply to Dr. Macnaughton Jones, wherein I attempted to point out that the adoption of any conventional phraseology, such, for instance, as the "borderland of insanity," would involve our profession in legal complexity and intrigue. Mr. Jessett has, however, to my great surprise, considerably exceeded Dr. Jones in this respect, and goes so far as to say that by "climacteric mania" he does not mean insanity, and that the term "mania," as applied to this disease, is certainly misleading, suggesting "mental disorder connected with the climacteric" as a more suitable term. It occurs to me, therefore, that a simple analogy should suffice to show the difficulty of accepting his suggestion, and for this purpose let us suppose that criminal offences committed under the influence of drink were regarded legally as insane actions, it would seem clear that a person who might suffer from slight mental disturbance under this condition could be properly designated (to paraphrase Mr. Jessett's definition) as a person suffering from "mental disorder connected with drink;" but supposing a person under a like condition were to evince suicidal or homicidal tendencies of a very threatening character, I submit that such person could then be appropriately described as in a condition of alcoholic mania, if I may employ the term. For a similar reason a person suffering from some slight mental disturbance under the climacteric period might be described according to Mr. Jessett's suggestion as suffering from "mental disorder connected with the climacteric"; but supposing this disorder attains that degree of intensity as to require the most "careful watching," mania, or some such term, is the only one, as I understand Drs. Goodall and Craig to intimate, which could give the case its practical and serious significance. If, therefore, Mr. Jessett objects to the term "mania," it is clearly incumbent upon him to supply a better; certainly it is not fair to leave us without one, the logical sequence of which would be that any case passing through the climacteric, which, he says, "is never insane in the first instance," but which culminates in unequivocal insanity, would have to be described under the one generic term, "mental disorder connected with the climacteric," which is nothing more or less than a deprivation of language.

I am, Sir, yours, &c.,
Clement H. Sers.
Queen's Road, April 19th, 1894.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Kindly permit us to correct an unfortunate error which occurs in our letter under the above heading in your issue of last week. We are represented as saying, in regard to the question of the retention of certifiable patients in single care, that "we have *no* direct cognisance of such cases." Precisely the contrary was intended. The correction is the more desirable since the phrase as originally designed is a suitable introduction to the final part of the sentence, in which we express our belief that the practice in question is widespread. The corrected sentence runs as follows:—"We have direct cognisance of cases in point, and if, as we believe, the practice in question is widespread, the risk to recovery—and to life itself—is obvious."

We are, Sir, yours, &c.,
E. Goodall & M. Craig.
West Riding Asylum, Wakefield,
April 20th, 1894.

JOURNALISTIC BOYCOTTING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—The independence and liberty of the Press is a subject-matter for pride on the part of every liberal-minded Englishman, but especially in medical literature our profession looks for, and, I think, rightly expects, independence in judgment and unprejudiced writing in the columns of its weekly periodicals. Unfortunately, of late, doubt has arisen in the minds of a large section of the medical profession as to whether some of the leading organs of medical opinion in this country are conducted with that wholesale disregard of cliquism and outside pressure so essential in journals that profess to reflect the mind of a large professional constituency, or to educate it in the higher ethical traditions which have been handed down to it. Once a doubt is engendered in the minds of the readers as to the honesty of purpose and independence of action of the proprietary or editorial department of a journal, immediately is its influence and weight depreciated, and its power for elevating the *morale* of the profession diminished. Few, I assume, will deny these general principles.

This much being admitted, I would respectfully ask why your contemporary, the *Lancet*, should allow any narrow and selfish spirit to actuate its conduct towards a large, important, and influential scientific society like the British Gynæcological, numbering some 500 members of the medical profession who have been duly elected its Fellows, and amongst whom are most of the eminent British, and not a few leading American, Australian, and Canadian obstetricians?

In fact, a more thoroughly representative and cosmopolitan society it would be difficult to find. Yet it is the proceedings of this Society that are refused a place in the columns of your contemporary. There must surely be some reason why its subscribers should be denied the advantage of perusing the valuable reports of gynæcological medicine and surgery, in the records of the cases which are regularly brought before, and discussed at, the meetings of this Society.

Let me here speak plainly and ask the question—can it be true, as is widely believed, that this process of journalistic boycotting has arisen out of an unavailing effort to discountenance and depreciate the status and work of the *special* hospital physicians and surgeons of the metropolis? It is well known that a rivalry exists between the obstetrical and gynæcological societies, and there is no reason why such rivalry should not lead to a generous and healthy competition in the scientific work of both. It is true that the "Obstetrical" has amongst its Fellows all the leading London general hospital obstetricians: the "Gynæcological" contains in its ranks all the leading provincial ones.

The lame excuse that it is not considered to be to the interests of the profession that two societies, obstetrical and gynæcological, should exist side by side in London, cannot for a moment stand, in the face of the work done by the "boycotted" Society, and the importance attributed to its proceedings all the world over.

Undoubtedly a large proportion of those who are Fellows of the Gynæcological Society are also readers of the *Lancet*. They, like ourselves, must regret and condemn the narrow policy which deprives them of the fair and just recognition of their work, and I would put it to those who are responsible for the conduct of this time-honoured journal, whether perseverance in so obviously biassed a course is calculated to maintain either its old prestige and character for independent action, or the reputation for those liberal traditions which have been so identified with its past.

I am, Sir, yours, &c.,
April 17th, 1894. Obstetricus.

◆

Medico-Parliamentary.

In the House of Commons, last week, the following questions were asked:—

Deaths from Carbolic Acid.

Mr. Acland, in reply to Mr. Macdona, said the Registrar-General could not give the number of deaths from poisoning by carbolic acid, but since the beginning of the year 42 deaths from that cause had been reported in the *Pharmaceutical Journal*. It was not expedient to place an article like carbolic acid, which was used for disinfecting and other purposes, under the restrictions of the Pharmacy Act, which would confine the sale exclusively to chemists and druggists, but the Government were considering whether an amendment of the law could not be made so that some precautionary regulations might be applied to the sale of carbolic acid and other poisons. He was afraid, however, that no law would restrain persons from committing suicide, but deaths from the accidental use of such compounds might probably be lessened by legislation.

Alleged Fatal Vaccination.

Mr. Hopwood—I beg to ask the Parliamentary Secretary to the Local Government Board whether his attention has been called to the death of a child named Simeon Dawson, who died after much suffering following on vaccination performed at Bury, in Lancashire; whether he is aware that the doctor who operated on and attended the child gave a certificate of death—"Primary, vaccination; secondary, pyæmia,"—and that the registrar of deaths declined to receive the certificate but gave an order for burial; whether the registrar sent up the above certificate to the Local Government Board, and was he justified in his refusal; what reply or communication has been made to him on the subject; and whether information was given of this case to the Royal Commission on Vaccination.

Sir W. Foster—The only information the Local Government Board have as to the cause of this death is contained in the certified copy of the entry with regard to the death in the register of deaths for the district. The cause of death entered was "Vaccination, pyæmia," and was certified "J. Silverwood, L.R.C.P." The death took place on the 3rd March last, and was registered on the 5th. The Board are informed that there is no foundation for the suggestion that the registrar declined to receive the medical certificate referred to. The Board received from the registrar a certified copy of the entry in the register on the 6th March, and on the same day the particulars of the case were forwarded to the Royal Commission on Vaccination.—(Hear, hear.)

Mr. Hopwood asked for what reason the certificate was sent up to the Local Government Board.

Sir W. Foster said the registrar pursued the usual course of informing the Board of any case of death after vaccination.

◆

Laboratory Notes.

WINE OF COD-LIVER OIL.

Messrs. Thomas Christy and Co. have submitted to us a sample of Stearns' "wine of cod-liver oil with peptonate of iron." This preparation, which is pleasant to take and free from objectionable smell and taste, contains 25 per cent. of cod-liver oil, with the addition of four grains of peptonate of iron to each fluid ounce. Such a combination will commend itself at once to medical men with fastidious patients to whom it is desired to administer this class of "medicine-food." The iron being in a readily assimilable form, does not tend to produce constipation or to provoke the disturbances of digestion to which most preparations of iron expose the patient, and it is stated, on clinical experience, that the patient's weight increases, in the majority of instances, in a more marked degree than with pure cod-liver oil, a large proportion of which is, as is well known, often found in the fæces, very little the worse for wear. We can confidently recommend this elegant pharmaceutical product in the treatment of phthisis and the various affections associated with or dependent upon the strumous diathesis.

STEARNS' CASCARA AROMATIC.

We have received from the same firm samples of "Cascara Aromatic," an aromatic sweetened fluid extract of cascara sagrada. The therapeutical properties of this valuable and fashionable laxative do not seem to be in the least impaired by the process of rendering it palatable; indeed, it may be regarded as a concentrated preparation, to be administered in correspondingly small doses (ten to thirty minims). We understand that Messrs. F. Stearns & Co., of Detroit, were the original manufacturers of Cascara in America, and the preparation under consideration differs only from the pharmacopœial extract in the fact that the bitter principle, which causes griping (and has no therapeutic value) is removed and simple aromatics substituted therefor.

Dike's Pepsin, from the same firm, is a non-hygroscopic soluble pepsin, perfectly free from mucus, and devoid of the musty odour usually associated with commercial samples of the ferment. It is presented in large, fluffy, silvery scales, and is altogether an elegant product.

ANTISEPTIC "MOUTH-PEARLS."

The well-known firm of Radlauer, of Berlin, have sent us samples of their "mouth-pearls" for disinfecting and deodorising the mouth and throat. These cavities are indeed the happy hunting ground of very numerous families of bacteria and cocci, pathogenic and otherwise. They it is that attack the teeth, provoking caries of these useful if not altogether indispensable dermal appendages. In these warm, moist, and spacious retreats, nestle the specific organisms of diphtheria and other infectious anginal affections, to say nothing of the comparatively innocuous germs whose *rôle* it is to impart a putrid odour to the breath. The extinction of even a part of the seventy or eighty micro-organisms whose *habitat* is the mouth is certainly a consummation devoutly to be wished. The agreeable odour which these pearls impart to the breath is a further advantage, at any rate, to those who are unfortunate enough to require such "respiratory cosmetics."

ANTINERVINE.

We have received from the same firm a sample of a new analgesic, to which the name of Antinervine has been given. Advantage may once more be taken of the opportunity to protest against this system of nomenclature, based on the supposed therapeutical application of this or that substance, a system which, if not nipped in the bud, will land us in confusion. Antinervine is a white, sparingly soluble powder of a somewhat agreeable taste. Like other remedies of the class to which it belongs (it is peptonised salicylbromanilide), it reduces the febrile temperature and subdues the symptom pain. It is, therefore, suggested for use in migraine, neuralgia, and in various disorders associated with an abnormally high temperature, such as articular rheumatism, pulmonary tuberculosis, &c.

◆

Medical News.

A New Hospital to the Memory of Livingstone.

An interesting ceremony took place at Dartford on Saturday, last when Mr. H. M. Stanley, of African fame, journeyed there in order to lay a memorial stone of a Cottage Hospital which is to be dedicated to the name of his eminent predecessor, Livingstone. The town was decorated in honour of the occasion, and a large concourse of people gathered to witness the ceremony. Mr. Ernest Hart said that no one better than Stanley knew the vast extent of the life and labours of David Livingstone, or their continuing and permanent influence on humanity. The medical profession welcomed Mr. Stanley that day as the one appropriate man to take the leading part in dedicating this Cottage Hospital as an enduring memorial to the great physician and African explorer. Mr. Stanley, after declaring the stone duly laid, delivered a lengthy address, in which he touched on the chief features of Livingstone's life and work. His good-humoured indifference to the discomforts of his wandering life was, he said, as marked as his gracious bearing towards the negroes. His hands were as free from violence as his lips were without guile. In dedicating this institution to one so great and so noble, they must think of him as of one who had yielded himself to a loving submission, and who laboured to the best of his means and with an extraordinary ability, awaking to the toils of the day and resigning himself without the least misgiving to the rest of the night, believing that the effect of his self-renunciation would not be altogether barren. A vote of thanks to Mr. Stanley brought the proceedings to a close.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons.

The following candidates have passed:—

Completing the Examination:—R. V. Brews, P. Coffey, J. M. H. Conway, R. L. Davies, E. S. L. Heard, H. E. Howley, T. F. Loughrey, T. C. Mackenzie, R. H. Moffit, F. J. Palmer, R. H. D. Pope, C. Powell, E. E. Roberts. B. Scribner, W. Taylor, T. A. J. White, T. F. Whyte.

Chemistry and Physics.—D. A. Faris, S. Jacob.

Pharmacy.—C. H. Cormac, H. M. Clarke. D. A. Faris, C. H. Fitzgerald, R. K. Galwey, A. W. A. Irwin, S. Jacob, C. J. Jones, J. F. O'Flanagan, R. W. Orpen, F. S. Walker.

Biology.—H. M. Clarke, C. H. Cormac, C. H. Fitzgerald, R. K. Galwey, S. Jacob, J. F. O'Flanagen, R. W. Orpen, W. Meagher, F. S. Walker.

Anatomy.—H. M. Clarke, C. H. Cormac, J. F. O'Flanagen R. W. Orpen.

Royal College of Physicians, Edinburgh; Royal College of Surgeons, Edinburgh; and Faculty of Physicians and Surgeons, Glasgow.

At the Quarterly Examinations for the Triple Qualification in Edinburgh, held during the present month, the following candidates passed the Final Examination, and were admitted L.R.C.P.E., L.R.C.S.E., and L.F.P. & S.G.:—

Harold Downes, George Prentice, Henry William Vaughan, John Jamieson Wallace, Charles Copland Piper, Patrick Gabriel Joseph Kennedy, Florence Hope Dissent, Mary Barnard, Reginald Edward Ingram Johnson, Wilson Ranson, John Garner, James Thornhill Woodhouse, Thomas Ernest Price, William Fleming Stevenson, Ernest Kinloch Johnstone, Catherine Mabel Blackwood, William Henry Tracey Vallange, Henry Paul Butterworth, Frank Carylon Rundle, David Stephenson, William John Gething, Elizabeth Marianne Erskine, William Atkinson Hardiker, Charles William Laver, John Gorman, Charles Wilfrid Lawson, Robert Alexander McWilliam Robinson, John Meade, Simon Finkelstein, Vivian Ernest Chang, Alfred Theodore Anderson, John Inchbald Johnson, Cecil Beaumont Roscrow, Grace Haxton Giffen, William Thomas Wood, John Hoggan Ewart, Cecil Gordon Foggs, William Henry Barnby, Horace Joseph Palmer, John Joseph Fitzgerald, Charles Ernest Conran, Edmond Frewen O'Ryan, Frederick William Clark, Joseph Henry Ensor Trout, William Owen Evans, Arthur Baillie Francis, Edward Haddon Ohlmus, and John Barrow Osborn Richards.

Notices to Correspondents, Short Letters, &c.

☞ CORRESPONDENTS requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

READING CASES.—Cloth board cases, gilt-lettered, containing twenty-six strings for holding the numbers of THE MEDICAL PRESS AND CIRCULAR, may now be had at either office of this Journal, price, 2s. 6d. These cases will be found very useful to keep each weekly number intact, clean, and flat after it has passed through the post.

LOCAL REPORTS AND NEWS.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

ORIGINAL ARTICLES or **LETTERS** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

MR. E. C.—The communication is of no practical interest to our readers.

MR. G. C. R.—Thanks, but we had previously made arrangements for reporting the lecture.

MR. JESSETT.—We shall be glad to receive the woodcut.

DR. R. P. HARRIS (Philadelphia).—We have marked your paper for early insertion.

DR. R. WILLIAMS (Preston).—We much regret the delay, which has been quite unavoidable. Proofs will be sent you during the next few days.

DR. SPENDER (Bath).—Eminently so.

MR. S. R. will find the subject of his communication has been treated in our present issue.

NOBLY DOING HER PART.

"YOUR husband is the editor of the *Bugle*, I believe?" said the neighbour who had dropped in to make a friendly call.

"Yes."

"And as you have no family and have considerable leisure on your hands, you assist him now and then in his editorial work, I dare say?"

"O, yes," answered the brisk little wife of the young newspaper man, hiding her strawberry-stained fingers under her apron, "I edit nearly all his inside matter."

QUÆRENS.—Our attention has already been called to the use in England of the medical prefix "Dr." by foreigners possessed of no British diploma, but although technically the assumption of a medical title exposes the delinquent to proceedings for infringement of Section XL of the Medical Act (1886), such actions are very difficult to bring to a successful issue, and are rarely brought. You might direct the attention of the Medical Defence Union thereto.

MR. NOBLE SMITH will receive a private note.

DR. V. G.—We have inquired as to the meaning of the inscription "Schweitz Coiffeur und Chirurgen Verband," and we are informed that it is only a fancy title devoid of any legal significance. At the same time the Association is interesting as bearing on the partnership which erstwhile existed in this country between the surgeons and barbers.

M. R. S.—Certain subjects lend themselves to discussion with advantage, and others, at any rate at certain stages, are best left severely alone, and this we imagine is the case in respect of the topic which you have selected as your theme. A few weeks hence the position may have changed, but for the time being we prefer an attitude of prudent reserve.

DR. P. H. (London).—The tabloids of thyroid gland referred to by Dr. Abraham (Medical Society, Jan. 8th, 1894) are prepared by Messrs. Burroughs, Wellcome & Co.—as might have been inferred from the term "tabloid," which is their property.

Meetings of the Societies.

WEDNESDAY, APRIL 25TH.

HUNTERIAN SOCIETY.—At 8.30 p.m. Discussion on Diphtheria. Dr. Newton Pitt: Etiology of Diphtheria.—Dr. Goodall: Clinical Relation to other Affections of the Throat and Occurrence as a Complication of Scarlet Fever and Measles.—Dr. Sidney Martin: Membranous Inflammations and the Characteristics of Diphtheria as a Disease (illustrated by lantern slides).—Dr. Washbourn: Facts bearing on Early Diagnosis, including the Employment of Bacterial Cultivation.—Dr. Hingston Fox: Mortality from Diphtheria contrasted with that from other Specific Fevers.—Dr. George Turner: Diphtheria and Sanitation. Dr. Thorne Thorne and Mr. St. Clair Shadwell have promised to speak.

THURSDAY, APRIL 26TH.

SOCIETY OF ARTS.—At 4.30 p.m., Sir Auckland Colvin: Municipal and Village Water Supply and Sanitation in the North-West Provinces of Oudh.

FRIDAY, APRIL 27TH.

CLINICAL SOCIETY OF LONDON.—Living Specimens at 8 p.m.:—Dr. Mott: Symmetrical Atrophy of the Hands.—Dr. Habershon: Amnesia with Right Hemiplegia in a young Hysterical Woman.—Dr. Rose Bradford: A case of Facial Hemiatrophy.—Dr. Hal[illegible]: A case of Muscular Dystrophy.—Mr. R. J. H. Scott: A case of Popliteal Aneurys[illegible] followed by Embolism of the Posterior Tibial Artery and Gang[illegible] the Foot.—Dr. Carr: An Unusual Form of Periph[illegible] Cayley: Multiple Cutaneous Fibrous Nodules associated [illegible] matism. Papers at 9 p.m.:—Mr. Barwell: A Mode of making Extension in Fractures of the Femur.—Dr. Lauder Brunton and Mr. Watson Cheyne: A case of Intestinal Obstruction due to Constriction of the Bowel after Appendicitis.—Mr. Silcock: A case of Acute Intestinal Obstruction and Peritonitis; Laparotomy; Incision and Drainage of Small Intestine above Obstruction; Cure.

Vacancies.

Balrothery Union—Swords Dispensary District.—Medical Officer. Salary £125 per annum, and £20 16s. 8d. per annum as Medical Officer of Health, with fees. Election 1st May. (See advert.)

Dewsbury and District General Infirmary.—House Surgeon. Salary (commencing) £80 per annum, with board and residence. Applications and testimonials to the Chairman of House Committee on or before May 1st.

London Hospital, Whitechapel, E.—Medical Registrar. Salary £100 per annum. Applications and testimonials to the House Governor not later than May 5th.

Lunatic Asylum, The Coppice, Nottingham.—Assistant Medical Officer (unmarried). Salary £120 per annum, with furnished apartments, board, washing, and attendance. Applications and testimonials to Dr. Tate at the Asylum.

North-West London Hospital, Kentish Town Road.—Resident Medical Officer and Assistant Resident Medical Officer. A salary of £50 attaches to the senior post. Candidates should attend a meeting of the Medical Committee on 1st May, at 5 p.m.

The Royal Hospital for Children and Women, Waterloo Bridge Road.—Resident Medical Officer. Salary £70 per annum, with furnished apartments and board. Applications and testimonials to the Secretary by April 25th.

Westminster Hospital, Broad Sanctuary, S.W.—Surgical Registrar. Salary £40 per annum. Applications and testimonials to the Secretary by 22nd May.

Appointments

COVEY, W. J., L.R.C.P.Lond., M.R.C.S., Assistant Medical Officer at the Infirmary of the parish of St. Pancras.

DENT, E. A., M.B., C.M., Assistant House Surgeon to the Devonshire Hospital, Buxton.

EDINGTON, G. H., M.B.Glasg., Resident Medical Officer to the Royal Hospital for Sick Children, Glasgow.

HARMAN, A. B., M.R.C.S., L.R.C.P., L.S.A., House Surgeon to the Royal Hants County Hospital, Winchester.

HERBERT, A. W. C., L.S.A., Medical Officer for the Borough of Southwold.

HOPE, E. W., M.D., C.M.Edin., D.Sc. (Public Health), L.R.C.P.Lond., Medical Officer of Health for the Liverpool Urban Sanitary District of the parish of Liverpool.

LAWSON, T. C., M.R.C.S., Medical Officer for the Ombersley Sanitary District of the Droitwich Union.

SHANN, H. C., L.R.C.P.Edin., M.R.C.S., Medical Officer to the York Workhouse.

TREVELYAN, E. F., M.D., M.R.C.S., Honorary Assistant Physician to the General Infirmary, Leeds.

URSDELL, H., M.R.C.S., Medical Officer of Health for the Buckfastleigh Urban Sanitary District of the Totnes Union.

WACHTER, C., M.D., Resident Assistant Surgeon (Ambulance Duty) to the Northern Hospital, Liverpool.

WATERS, A. J. G., L.R.C.P., L.M.Ed., M.R.C.S., Medical Officer for the Third Sanitary District of the North Witchford Union.

WILKIN, R. H., L.R.C.P.Lond., M.R.C.S., Medical Officer for the Fifth Sanitary District of the Risbridge Union.

Births.

COOPER.—April 17th, at Southwood, South Croydon, the wife of H. J. Cooper, M.A., M.B., B.C.Cantab., of a son.

GOODALL.—April 16th, the wife of Dr. E. W. Goodall, of the Eastern Hospital, Homerton, of a daughter.

GOULLET.—April 19th, at 10 Blenheim Place, Grove End Road, N.W., the wife of Charles A. Goullet, M.R.C.S., L.R.C.P., of a son.

MARTIN.—April 19th, at 33 Bermondsey Square, London, S.E., the wife of F. G. C. Martin, L.R.C.P., M.R.C.S., of a daughter.

Marriages.

REECE—PERKINS.—April 18th, at Whitchurch, Edgware. Ric[illegible] James Reece, M.D., only son of the late George Reece, of Kensington, to Ada Eleanor, only child of J. Watt Perkins, of Edgware.

SCOTT—BROOKHOUSE.—April 19th, at St. Thomas' Church, Nottingh[illegible] Thomas Graham Scott, M.R.C.S., L.R.C.P., of Denmark Hil[illegible] London, to Emily Hannah Halford, second surviving daughter [illegible] Joseph O. Brookhouse, M.D., M.R.C.P., of Nottingham.

Deaths.

BLAKE.—April 19th, at his residence, Acre House, Sherborne, Th[illegible] Blake, M.D., L.R.C.P., late of Salisbury, aged 75.

CONNOR.—April 14th, at his residence, 79 Hill Street, Newry, Sam[illegible] Connor, Surgeon, J.P., aged 57.

KELLIE.—April 22nd, at 32 St. James's Square, Notting Hill, Bri[illegible] Surgeon Jas. Kellie, M.D., late of the 17th Lancers and Ro[illegible] Horse Artillery, aged 69.

MORRIS.—April 19th, at Chipping Camden, Gloucester, Chas. [illegible] Morris, M.R.C.S., L.S.A., aged 66.

WAKEFIELD.—April 12th, at Prince's Square, London, W., Surge[illegible] Colonel H. Wakefield, Bombay Medical Service, aged 65.

The Medical Press and Circular.

ON CASTRATION IN FEMALES:

ITS FREQUENT INEXPEDIENCY AND THE SIGNAL ADVANTAGES OF CONSERVATIVE SURGERY IN THESE CASES.

By C. H. F. ROUTH, M.D., M.R.C.P.Lond.,

Consulting Physician to the Samaritan Hospital for Women, the North London Consumption Hospital, &c.

Part II.

What is the condition, mental and physical, which obtains in a castrated woman? I care not if it be said that the mortality is small. But what are the symptoms in after life? Dr. Geo. H. Savage in a paper on "Some Neuroses of the Climacteric and Summary of Climacteric Cases at Bethlem" makes a remarkable admission that in the Library of the Royal College of Surgeons he did not find a single entry under either of the heads climacteric, change of life, or menopause. Two books only were found. One in English on "Change of Life" by Dr. Tilt, which he characterises as excellent, only a little too full of vasomotor explanation, some in French by Dr. Gardann. In fact the full phenomena of change of life in modern data has yet to be written, but is it not equally the case with the results of castration in the female? Operators are glad enough to tell you how many cases they have operated upon, and that their patients recovered from these operations, but what became of these women later on, that is the question to be answered. But on this point they are almost entirely dumb.

First, as regards the ovary itself. If any healthy part of it is left behind, it will do its work. Several examples are given of pregnancy following partial castration, to which I shall make reference in the sequel. But more lately Dr. Airstoff (*Lancet, Medical and Surgical Reporter*) has published a dissertation on the compensatory hypertrophy of the ovary, from materials obtained from the Pathological Medico-Chirurgical Academy under Professor Wanoski, from which he shows that when one ovary is removed the other one increases in size and weight, the follicles coming more rapidly to maturity and withering more quickly, besides which the medullary layer increases. In observations made on rabbits, it was found that the hypertrophic process (physical and mental changes after castration of annexes and ovaries) had begun within two months after the operation, and that at three or four months the remaining ovary had nearly doubled its original size. After the fifth month the remaining ovary became smaller again. (*British Gynæcological Journal*, Nov., 1893, p. 342). This is after all what we should have expected, and should act as a caution to surgeons not to remove a second ovary lest it should become diseased. Even if this be healthy its removal has unfortunately been recommended as the safest course to pursue. Such is not improbably a surgical delusion.

Climacteric changes closely resemble those following castration.—Dr. Savage speaking (Medical Press, Nov. 8th, 1893) before the Medical Society has put in a very interesting form before us some of the physical troubles of the menopause. Those who fancy something has burst in their heads or wombs, who describe the feeling as one of hot blood over the brain surface or partial loss of brain, or deadness or emptiness, all of which he has no doubt are due to disorder of the reproductive organs either at the onset or ending. He dwells particularly on the development of hair on their faces so much more commonly produced at the menopause, which may develop an accompanying suicidal tendency. This hirsuteness may also occur after removal of the ovaries. Again with the passing away of the sexual function, querulousness, jealousy, imagination that they are no longer cared for by their husbands, not infrequently occur.

Fully developed insanity occurs generally in the form of melancholia. Out of 54 Bethlem cases, 32 were melancholia, 10 maniacal, 7 suffered from delusional insanity, 3 from mental weakness, and 2 were general paralytics. Dr. Savage dwells also upon the disorders of the senses, and specially those of hearing and smelling—and the hankering after strong drink. The perverseness of the sexual function or sympathetic side of the woman at such times is apparent in home relations, some lose all sexual feeling, and imagine they are shunned for this reason by their husbands. But in some there is a distinct revival of the sexual function, and this is combined with cunning, deceit, untruthfulness and dishonesty, attentions are misinterpreted, and they may pass away from a virtuous course of life. In others this passion passes all bounds and nymphomania results.

But Dr. Savage concludes with this definite opinion, "The ordinary symptoms of the climacteric may be induced prematurely by oophorectomy, and I have some experience that the morbid exaggerating may also occur under similar conditions. Indeed all those who have discussed this question repeat this general statement. Among the later writers Martin, in his paper read before the Gynæcological Society, affirms that the artificial menopause is accompanied by the same peculiar nervous disturbances which characterise the natural climacteric (p. 279, November, 1893). The same is asserted by Dr. Champney in his last paper in the "Bartholomew's Reports" on removal of appendages. "The menopause he says with all its accompaniment occurs (p. 55). Amongst other symptoms he refers to the occurrence of vasomotor disturbances, flushings, abdominal swellings, faintness, neuroses, &c., sometimes great obesity. The sexual organs shrink, vagina and uterus become atrophied, breasts shrivel, and of course sterility." There is, no doubt, that many of them on realising their degradation are like eunuchs made intensely miserable, a feeling which extends often to the husband who thereby thinks himself dishonoured. Dr. Champney lays great stress on the loss of the feelings of motherhood. This men cannot appreciate, but to women it is often an agonising lifelong misery, if not shame. Last not least though surgeons have become very skilful in castrating

---

(a) Paper read before the British Gynæcological Society, April 19th, 1894.

women, still the mortality is not to be set aside too readily. Dr. Champney expresses this strongly: "There can be no doubt that free removal of the appendages has killed many women unnecessarily."

It is well to say a word on the unsexing of the castrated female. Some are said to lose all sexual organism, others to have it intensified.

Climacteric changes resembling those of castration.—Upon this point also Mr. Knowsley Thornton states (Medical Society of London's "Transactions," vol. xiv, p. 255), with regard to unsexing, again affirming, as he had often done before, that removal of both ovaries in a woman who had no supernumerary ovary, did unsex her, and destroyed the sexual desire and pleasure. He affirmed this as the result of careful inquiry addressed some years ago to all the patients on whom he had performed the double operation either in ordinary ovariotomy or in the operations under consideration.

I think it will be admitted that operations on the sexual organs of a female favour insanity in some form. In hysterectomy Dr. T. Keith put it down as ten per cent., and I suppose in these cases the ovaries and tubes were also removed. Even we find it affirmed (*Lancet* I, '85, p. 522, Barwell's paper): Insanity often occurs after ovariotomy. Barwell, Lawson Tait, Alban Doran have all given instances. Meredith also states that many cases of insanity had occurred after ovariotomy, usually within a week after operation. Dr. Edis has mentioned one also.

This subject has been lately discussed by Dr. A. H. McFarland in a paper which was published in the *Annals of Gynæcology and Pediatry* for October, 1893. After mentioning Dr. Spitzka's and Dr. Richard Dewey's opinions, who leave the question very much where they found it, still unsettled, Dr. McFarland remarks, "While pelvic and abdominal diseases of women are more frequently and intelligently recognised by the profession now than formerly, it may be affirmed that more women, ten to one, have been consigned to hospitals for the insane (victims of needless or unskilful surgical operations) than have been restored to reason by the most commendable and skilful abdominal surgery." (*British Medical Journal*, November, 1893.) Dr. J. M. Baldy read a paper before the American Gynæcological Society on "Insanity following Laparotomy," in which he gave statistics from insane asylums of Pennsylvania in regard to the number of patients received after laparotomy. From 18 institutions he received reports of 15 cases, and he himself had one case of melancholia after an operation for rectocele, and another with chronic confusional insanity after oophorectomy. One of the conclusions of this paper *in primis* is that gynæcological operations are more likely than any other surgical procedure to disturb the mind.

Effects of removing annexes.—In the Medical Press of November 22nd, 1893, reference is made to Professor Chroback's view on the advantages and disadvantages of operating on uterine appendages. He points out the great difficulties in drawing honest conclusions therefrom, as the statistics are not sufficiently reliable. Rosthorn operated on 106 cases who visited the Hospital of Vienna, and endeavoured to learn the results by a Fragebogen, *i.e.*, a schedule of appropriate questions on their present state of health. Only 40 replied. The difficult question is, "Are they able to perform their usual duties afterwards." It certainly involves sterility in most cases. But the danger of the operation is small. (Professor Winter makes the mortality 3½ per cent., Schauta and Chroback 4·1 per cent.), but sometimes a psychical change takes place which must never be lost sight of in our premonitions.

The result of the Fragebogen was :—

1. State of general health—8 good, 24 improved, 3 unchanged.
2. Ability for work—26 able, 16 improved, 6 unable.
3. Assimilation—29 improved, 1 the same, 13 emaciated.

From 40 published cases by Rosthorn, 3 are reported to have died shortly after the operation, 20 recovered, 20 healed, 4 unhealed, 13 improved, 1 remained without history. A later history of 30 cases gave 19 who were perfectly healed, 4 improved, 4 remained unhealed, and 3 died. From this it is concluded that half the cases have a satisfactory result. On the other hand Schauta receives these statements with great incredulity as the unrecorded cases would outweigh this result. Again statistics showed very few cases died from pyosalpinx. Many recovered by massage, but if rupture occurred, the perforation and peritonitis were so rapid they died before reaching the hospital. In many of the cases he had operated upon severe central disturbance ensued which led him to believe there was a much closer connection between the nerve centres and the genitals than we had calculated upon. He had operated on 213; 121 had been heard of, 100 had replied favourably, 17 were freed from their former symptoms, while 4 remained unchanged. Careful consideration of the whole case was therefore still a great *desideratum*.

Mortality from Diseases of the Adnexa. Comparing cases left to themselves with cases operated upon.

Here we must distinguish between the usual mortality from these diseases without operation, and after operation. The latter class to be again sub-divided into those cases treated per vaginam, and secondly into those treated by abdominal section.

Dr. Grigg has given us a very graphic account of seven cases of ruptured pyosalpinx which occurred at Queen Charlotte Hospital during or after labour. This is a very sad complication, the more so as I do not see how the existence of this disease, entirely unsuspected, could have been diagnosed in time. It would be needful to examine every pregnant woman, which could never be, before labour. But we may trust that after that paper it would be at once diagnosed like a case of ruptured ectopic gestation and operated upon once it had burst. But if only seven cases were observed out of the thousands of women confined in that hospital the disease must be exceedingly rare.

Dr. Lewers has published a very able paper on the "Pathological Conditions of the Fallopian Tube" (Medical Society's Transactions for 1887). He found 17 cases of gross tubal disease out of a hundred women carefully examined in the dead house, but in no case was death produced by the disease. Dr. Galabin, out of 302 post-mortems at Guy's, found the number to be only 12 or 4 per cent., and the number of cases of pyosalpinx, was still smaller, two cases. There were 14 cases of chronic inflammatory disease, or 9 per cent. about the Fallopian tubes without distension. Death had probably indirectly resulted from perimetric inflammation in about 2·3 per cent.

Dr. Kingston Fowler's post-mortem cases are still more remarkable. In three years, 1882, 1883, and 1884, and through the courtesy of Dr. Kingston Fowler I am enabled to give now the full data, the total number of post-mortems made at Middlesex was as follows :—

Year.	Medical.	Surgical.	Total.
1882	178	110	288
1883	182	112	294
1884	167	92	259
	527	314	841

Out of this 841 total, there were found 15 cases of pyosalpinx and hydrosalpinx. "But in none of these cases was the disease suspected during life. Partly also from the fact that all the cases were complicated by some other general or uterine disease which would render doubtful to what degree any symptoms observed were due to the state of the Fallopian tubes, and also because in most of the cases, the reports of the post-mortem appearances clearly indicate the course of the disease and the sequence of the several events which together brought about the patient's death."

These cases so fully and faithfully given and evidently with so much impartiality, have been often quoted as proving the great seriousness of the disease and its great mortality, but I think with the above lucid description given in a few words and so very forcibly put by Dr. Fowler, such a conclusion is scarcely warranted, or intended by the author, especially now as we know the total number of post-mortems made in the three years. Thus far they can now be compared with Drs. Lewers' and Galabin's cases. In the first place Dr. Fowler distinctly states that in none of those fifteen cases was the disease suspected during life. Have we not some reason, therefore, in hoping from experience in other cases, that if they had been diagnosed, perhaps some might have been cured; and lastly, one objection which I think has great weight has been made by Dr. Champneys: "In Middlesex Hospital the autopsies include a number of cancer cases from the cancer wards. In five of the fatal cases cancer existed, and in one there was a large fibroid. All that these cases therefore prove is that cancerous women may actually die with intercurrent tubal disease. As it is, it proves that out of 841 cases, 15 only died with diseased tubes in the three years, *i.e.*, giving a mortality only of 1 per cent.

This result is contrary to what has been stated. Dr. Lewers tells us that in none of his 100 cases was death produced by the disease. Out of 302 cases Dr. Galabin gives the percentage mortality at 4 per cent, and Dr. Kingston Fowler at 1·7 per cent.

It would seem, however, from these preceding data that if the cases had been left to themselves the mortality would have been less, as a general rule than it was on those operated. For the actual mortality after operation is more formidable except with Mr. Lawson Tait, who puts down his deaths, out of 474 cases, at 2·5 per cent.

Dr. Cullingworth in his paper read before the Obstetrical Society, puts it down at 8 per cent. on 50 cases.

Dr. W. Duncan, 30 cases and 1 death, *i.e.*, 3·3 per cent.

Dr. Byford, 24 cases, 2 deaths or 8·3 per cent., and at the Samaritan Free Hospital from 1880 to 1893, 66 cases, mortality 5, equal to 8·3 per cent.

Dr. Cushing, in the *Pacific Journal* for July 1890, gives us also a summary of 14 cases in which abdominal section for removal of uterine appendages, not the seat of tumour, was performed by various gynæcologists, with only 1 death equals 7·1 per cent. These numbers differ greatly, but it is manifest that a great deal depends on the nature of the cases operated upon. For instance in Mr. Tait's cases there were 179 cases of pyosalpinx, 37·7 per cent. In Dr. Cullingworth, 20 cases, equal 40 per cent. In Dr. Duncan's, 2, equal 6·6 per cent. Dr. Cushing, 7 cases, or 50 per cent. Comparison therefore gives no idea of the merits of the operation.

Professor Winter has a mortality of 3½ per cent. Schauta and Croback, 4·1 per cent., and Martin, out of 27 cases, lost 1, equal to 3·7 per cent. Dentu extirpated the annexes in 48 cases, but this number included 4 ectopic gestation cases. Before 1890, at the Hospital Necker, 18 cases with one death only. Since 1890, he had extirpated the annexes in 30 cases; 14 of these were chronic salpingitis, cysts, hydrosalpinx, &c., all cured. Twelve were cases of pyosalpinx with 2 deaths, 4 were cases of ectopic gestation, with 1 death. Omitting these last 4, we have 44 cases of removal of the annexes with 2 deaths, 4·5 per cent.

Again, Bouilly had 33 laparotomies for pyosalpinx, and 4 deaths, 12 per cent.

Segond had 23 hysterectomies for removal of appendages with other lesions of tubes and ovaries with 4 deaths, 17·4 per cent.

Doleris had 84 cases, laparotomies with 4 deaths, 4·7 per cent.

Richelot, 103 laparotomies for diseases of annexes, with 4 deaths, 3·8 per cent.

And yet, if we are to believe the French surgeons, they appear to think that it is almost innocuous to remove the appendages, although some openly condemn the operation as frequently nothing better than mutilation. "The mortality from operations in these cases," says Doleris (see his paper, "Trop de Mutilations Inutiles, Nouvelles Archives d'Obstetrique et Gynæcologie," vol. 7, p. 403) is another surprise. It seems to have become a negligable quantity. Some writers simply speak of it, others announce it very precisely, but only for recent and limited periods, omitting all earlier dates. Again, others regard the mortality from these operations as not possible." In fact, to spay a woman unless also suffering from other serious diseases, is like spaying cattle, considered of no moment.

RODENT ULCER:

A CLINICAL STUDY BASED ON TWENTY-EIGHT CASES.

By ROGER WILLIAMS, F.R.C.S.,
Late Surgical Registrar, Middlesex Hospital, &c.

The recent discussion on rodent ulcer at the Pathological Society reminds me, that although during the last quarter of a century, numerous additions have been made to our knowledge of the histology of this disease, the study of its clinical features has been neglected. Hence less is really known of this form of cancer than of any other variety of the disease. Under these circumstances the following analytical study of twenty-eight cases recorded by myself when Surgical Registrar to the Middlesex Hospital, will probably be of interest.

A. Males (14 cases).

Age.—The earliest age at which the disease was first noticed was 26 years, the latest 70, and the mean age was 44·4 years.

When *first seen* by me the youngest was 34 years of age, the oldest 72, and the mean age was 54·6

The numbers for each quinquennial period were as follows:—

Age when first noticed—25 to 30 years, 2; 30 to 35, 2; 40 to 45, 3; 45 to 50, 4; 55 to 60, 2; 65 to 70, 1; the average being 44·4.

Age when first seen—30 to 35, 1; 35 to 40, 1; 45 to 50, 3; 55 to 60, 5; 60 to 65, 3; 70 to 75, 1; the average being 54·6.

The Total Duration of Life.—There were only two fatal cases, and in these the total duration of life, dating from the commencement of the disease, was 21 and 9·3 years respectively.

In the former of these cases no operation had ever been done.

In the latter the primary disease, which began near the inner canthus, was excised a year after its commencement, and the eye was enucleated. There was recurrence *in situ* before the wound had healed. Six years later this recurrent disease, which during the last year had taken on quasi-epitheliomatous characters, was freely dissected out, and the actual cautery was afterwards applied. Recurrence set in six months later, and this was again dissected out, but it returned a few months afterwards. There was no further operation. He died of asthenia a year and a quarter afterwards, with the disease progressing. There was no necropsy.

Duration of Life to Admission.—In 14 cases the duration of life from the commencement of the disease to admission was as follows:—

The shortest period 1 year, the longest 25 years, the average 10·4 years.

The subjoined statement further illustrates this subject.

The duration was from 1 to 5 years in 3 cases.
" " 5 " 10 " 5 "
" " 10 " 15 " 3 "
" " 15 " 20 " 2 "
" " 20 " 25 " 1 case.

Seat of the Initial Lesion.—This was noted in 13 cases. In every case the disease began in the skin. Its situation was as follows:—

Nose in 8 cases (side of, near right inner canthus in 3; side of, between level of inner canthus and ala nasi in 3—right 2, left 1—; ala nasi in 2—right 1, left 1).

Eyelid in 2 cases (lower, near right inner canthus 2).

Cheek in 2 cases (over right malar bone 1, near middle of right naso-facial groove 1).

Forehead in one case (over the left frontal eminence).

Character of Initial Lesion.—Pimple in 4 cases, small sore in 2 cases, speck in 2 cases, wart in 2 cases, lump, nodule and scurfy patch, each in 1 case. With regard to the *size* of the initial lesion, when first noticed it is described as being like a pin's head in 4 cases, small in 4 cases, pea-like in 2 cases, like a split-pea in 2 cases, and like a threepenny piece in 1 case.

Civil State.—Of 12 individuals, 8 were married, 3 widowers, and 2 were single.

Occupation.—Carpenter in 3 cases, police inspector, joiner, printer, servant, bricklayer, farm labourer, tin-plate worker, railway porter, coal porter, and boot-maker, each in 1 case.

Ætiological.—Of 11 cases in which inquiries were made there was history of *previous injury* in 1; in this case the disease began as a small hard knob, in the seat of a wound caused by a piece of glass, a short time previously.

Of 11 cases there was history of *previous disease* at the seat of the initial lesion, in 1—a congenital wart.

With regard to *syphilis* inquiries were made in 8 cases, and in 2 there was distinct evidence of the disease.

Previous Health.—Of 10 cases the previous health had been good in 9 (with no serious illness since youth in 3), and indifferent in 1.

The following previous diseases are noted as having occurred since childhood:—Rheumatic fever in 3 cases, small-pox in 2 cases, and erysipelas in 1 case.

FAMILY HISTORY:—(A) *The Occurrence of Cancer.*—Of 11 families in which this was specially investigated, there was history of cancer in 2 (18·18 per cent.). In one case the patient's father died, æt. 66, of cancer of the *œsophagus*, and in the other the patient's maternal grandmother died, æt. over 80, of cancer of the *skin of the thigh.*

(B) *The Occurrence of Tumour.*—Of 10 families there was history of tumour in 2. In one of the cases the patient's mother died, æt. 60, of *abdominal* tumour; in the other a daughter of the patient's sister died of *abdominal* tumour (this is the case in which the patient's maternal grandmother died of cutaneous cancer of the thigh).

(C) *The Occurrence of Phthisis.*—Of 8 families one or more members had died of phthisis in 3. The relatives thus affected were the father, brother, and sister, each in one family. In one instance there was history of phthisis and tumour in the family—the patient's mother died of abdominal tumour and her sister died of phthisis.

(D) *The Occurrence of Insanity.*—Of 5 families there was history of insanity in 1, the patient's father died insane, æt. 66.

(E) *Consanguinity in the Parents.*—As to this inquiries were made in 3 cases with negative resul[illegible]

State on Admission.—(*a*) Of 7 primary [illegible] well nourished, 1 moderately nourished, 1 pale, and 1 was sallow. In three cases the complexion was noted, all were dark. In these 7 cases there was no instance of enlargement of the adjacent lymphatic glands. Two of them presented old syphilitic scars on the legs, and 1 ulcers as well. In another case the capillaries of the cheeks were unduly obvious.

(*b*) Of 7 recurrent cases, 2 were well nourished, 2 moderately nourished, 1 ill-nourished; and 2 were pale, 3 were of fair, and 1 of dark complexion. In 2 cases the recurrent disease had assumed a quasi-epitheliomatus appearance; and in each of these cases there was a single enlarged lymph gland over the masseter muscle, just below the zygoma.

In the other 5 cases there was no lymph gland enlargement.

In every case the recurrent disease, appeared at the seat of the pre-existing disease. In one of these cases, in which the whole of the left half of the forehead was involved, nearly the whole of the diseased area had healed, and remained so for several years. This patient was admitted with rather recent outbreak of spreading ulceration at the upper edge of this scarred area.

In all of the above 14 cases the lesion was single.

Treatment, Result, &c.—Of 12 cases, the interval between the commencement of the disease and the first operation, averaged 6 years. The longest interval was 15 years, the shortest, 1 year (2 cases).

Of 9 cases, the extent of the primary disease at the time of the first operation is stated as follows:—the size of threepenny-piece in 2, of sixpence in 2, of a shilling in 3, and of half a-crown in 2 cases.

In 4 cases the primary disease had been destroyed by *caustics*, in 3 there was recurrence shortly afterwards, in 1 case the ulcer healed and remained so for several years, when the ulceration recommenced.

In 8 cases the primary disease was *excised*, and in 3 the orbit was cleared as well. All these patients recovered, the average period of convalescence being 48 days. The subsequent history of 3 of them is unknown. Of the other 5 cases in all there was recurrence: 2 years after the operation in 1 case, one year after it in 1 case, and a few weeks after it in 3 cases.

In 10 cases of first recurrence, the disease was again excised, the orbit being cleared as well in 1.

In these cases the period that had elapsed since the first operation averaged 5·6 years, the minimum was a few weeks, the maximum 17 years.

In 3 of these cases, the recurrent disease presented a quasi-epitheliomatous appearance, and in one of them the disease disseminated in an adjacent lymph gland. All recovered from the operation, the average period of convalescence being 62 days.

The subsequent history of 5 of them is unknown. In the other 5 cases the disease recurred; 6 months after operation in 2 cases, a few months after in 1 case, 2 months after in 1 case, and a few weeks after in 1 case.

In 4 cases of second recurrence, the period of immunity was a few weeks in 1 case, 6 months in 2 cases, and 1 year in 1 case.

In all of these cases, the recurrent disease was again extirpated; in 3 by dissection, with clearing of the orbit 1, and in 1 by scraping. All recovered from the operation, and the period of convalescence averaged 67 days.

The subsequent history of 2 of these cases is unknown. In the other 2 cases recurrence set in at 1 month and 6 weeks respectively after operation. One of these patients died of asthenia, with the recurrent disease progressing, 1½ years later.

In 1 case a third recurrence was excised, and an adjacent enlarged lymph gland was dissected out;

since the last operation, 6 weeks previously, the disease having assumed a quasi-epitheliomatous aspect. The patient was convalescent 41 days after the operation.

Causes of Death.—Of the 2 fatal cases, 1 died of asthenia with the disease progressing, after stay in hospital of 520 days. The nose, orbit and adjacent parts of the cheek were extensively destroyed by ulceration having thick, hard, raised, everted edges. There was no necropsy. The total duration of the disease was 9·3 years.

The other patient died of phthisis, with the disease progressing. In this case no operation had ever been done. The total duration of the disease was 21 years. At the necropsy the body was emaciated. The left orbit, eye, cheek, and the whole of the nose were completely destroyed. In their place was a large ulcerated cavity, which communicated with the mouth by an ulcerated opening through the hard palate. The bones of this region were exposed and in places necrotic. There was no dissemination in the adjacent lymph glands, nor were there any metastatic growths. Old fibrous adhesions over both lungs, each of which presented several cavities and extensive deposits of caseating tubercle, which in many places had broken down. The other organs were normal.

B. Females (14 Cases).

Age.—The earliest age at which the disease was first noticed was 14 years, (*a*) the latest 66, and the mean age was 42·1 years.

On first coming under my notice the youngest was 29, the oldest 80, and the mean age was 53·6 years.

The numbers for each quinquennial period are as follows:—

Age when first noticed.—Under 25 years, 1; 25 to 30, 1; 30 to 35, 1; 35 to 40, 2; 40 to 45, 3; 45 to 50, 3; 50 to 55, 2; 65 to 70, 1; average, 42·1.

Age when first seen.—25 to 30, 1; 40 to 45, 1; 45 to 50, 3; 50 to 55, 4; 55 to 60, 2; 70 to 75, 1; 75 to 80, 1; average, 53·6.

Total Duration of Life.—In 2 fatal cases the total duration of life, dating from the commencement of the disease, was 15·8, 12·18, and 9·7 years respectively. All of these cases had undergone operation. In the first case the disease had been excised 1·8 before death, and there was no other operation. In the second case the disease had been first destroyed by caustics 4·18 years before death; 3·75 years after this operation recurrence was excised and the orbit cleared; shortly afterwards caustics were again used. In the third case the disease was first excised 6·7 years before death, and the operation was repeated several times during the next four years.

Duration of Life to Admission.—The shortest period, 2 years (2 cases), the longest 30 years, the average 11·3 years. The following statement further illustrates this subject:—

The duration of the disease was from 1 to 5 years in 3 cases; 5 to 10 in 3; 10 to 15 in 4; 15 to 20 in 3; 25 to 30 years in one case.

Seat of the Initial Lesion.—In every case the disease was of cutaneous origin. It began in the following situations:—

Nose, in 11 cases (side of, near inner canthus in 7, right 4, left 3; just above the right ala nasi in 2; on the right ala nasi in 1).

Temple, 1 case (one inch behind the left external angular process and one inch above the zygoma).

Upper lip, 2 cases (just below the ala nasi—right 1, left 1).

Character of the Initial Lesion.—Pimple in 7 cases, sore in 3, wart in 2, red spot and white speck, each in one case. In all these cases the initial lesion was very small.

Civil State, &c.—Married 7, widowed 3, single 4. Of 8 housewives, one worked as a laundress as well; of 2 widows, one was a nurse and the other was engaged in housework; of the single, one was a cook, one a laundress, and one a governess.

Of 7 who had lived in wedlock, all were fruitful; the maximum progeny 11 children and 2 miscarriages; the minimum 3 children; the average 6·8 children and 2 miscarriages each.

Catamenia.—Regular in 4, (profuse 1). Climacteric at 47, 48, and 50 years, in the 3 cases in which it was noted. In 3 the disease began before the climacteric, and in one after it.

Ætiological.—Of 14 cases there was history of previous injury in 3, scratch 2, blow 1. Of 13 cases there was history of previous disease at the seat of initial lesion in 2, congenital mole 1, wart of 18 years' duration, 1.

With regard to syphilis, inquiries were made in 11 cases with negative results.

Previous Health.—Of 12 cases, good in 10, (with no serious illness since youth in 5), indifferent in 2.

The following previous diseases are noted: typhoid fever in 2 cases, diphtheria, pleurisy, rickets, and myopia, each in one case.

Family History:—(a) *The Occurrence of Cancer.*—Of 13 cases there was history of cancer in one family, the patient's sister having *rodent ulcer* of the nose.

(b) *The Occurrence of Tumour.*—Of 13 cases there was history of tumour in one family, the patient's sister having died of *internal* tumour.

(c) *The Occurrence of Phthisis.*—Of 12 families there was history of phthisis in 2, in both cases several of patients' brothers and sisters having died of the disease.

(d) *The Occurrence of Insanity.*—Of 5 families there was history of insanity in 2; in one case patient's sister committed suicide, and another sister was at the time insane; in the other case the mother's sister died insane, as also did the patient's brother.

Consanguinity in the Parents.—As to this inquiries were made in 4 cases with negative results.

State on Admission.—Of 6 primary cases, 4 were well nourished, 2 ill-nourished, and one was pale. In two of the cases a large extent of the rodent ulcers had healed. Of 8 recurrent cases, 5 were well nourished 1 obese, 1 moderately nourished, 2 were pale, and 1 sallow.

One of the patients was a dwarf with extreme rachitic deformity of the skeleton. In 2 of these cases the disease had assumed a quasi-epitheliomatous character, and the adjacent lymph glands were enlarged. 7 of the patients were fair complexioned and 5 dark.

Treatment, Result, &c.—Of 14 cases the interval between the commencement of the disease and the first operation averaged 9 years: the shortest period 1 year, the longest 30 years.

In 12 cases the extent of the primary disease at the time of the first operation is stated to have been as follows:—size of sixpence in 4, crown in 3, half-crown in 3, shilling in 1, and threepenny piece in 1 case.

In 6 cases the primary disease had been destroyed with caustics; in 5 there was recurrence 4 years, 2 years, 1 year, a few months, and 2 months respectively afterwards. In 2 of these cases the disease assumed epitheliomatous characters in its subsequent course, and the adjacent glands became infiltrated. Of 1 case the subsequent history is unknown.

In 8 cases the primary disease was excised. All recovered from the operation, the average duration of convalescence being 33 days. The subsequent history of 2 of these cases is unknown. Of the others, 6 in all, recurrence took place, 2 months, 4 months, 14 months, 1½ years, 2 years, and 5½ years respectively, afterwards. In none of these cases were the adjacent lymph glands involved.

Of 9 first recurrences, the disease was excised and the orbit cleared as well in 4. The interval since the

---

(*a*) For an account of this case, *vide Brit. Med. Jour.*, Sept. 10, 1890, first operation averaged 2·3 years. In 2 of these cases, the disease had assumed a quasi-epitheliomatous aspect, and the adjacent glands were enlarged. All recovered from the operation, the average period of their convalescence being 26 days. The subsequent history of 3 of them is unknown. Of the others, 1 died of phthisis 67 days after operation, in the remaining 3 cases, recurrence set in 1 month, a few months, 1 year, 2 years, and 2½ years respectively, after the last operation.

Of 4 cases of second recurrence, the intervals since last operation were 4 years, 2½ years, 2 years, and 1 month respectively. In 3 of these cases, the recurrent disease was again excised, both recurred from the operation, but their subsequent history is unknown. The other case was treated with caustic, and there was recurrence a month afterwards.

In this last case, a third recurrence, like epithelioma, with lymph gland infiltration, was excised, together with part of the inferior maxilla, 2½ years later. The patient recovered from the operation, but her subsequent history is unknown.

Causes of Death.—Of the 3 fatal cases, 2 died of *Asthenia*, and 1 of *Phthisis*.

Necropsies.—Of these there were 3.

The *general condition* of the body in all was that of extreme emaciation. In one case the body was that of a dwarf, owing to infantile rickets; the skeleton was greatly deformed, the femora and tibiæ especially being stunted and bent.

The *local disease*:—

(1) The left orbital region, eye, nose, adjacent parts of face, forehead, and upper lip entirely destroyed, and replaced by an irregular ulcerated chasm, at the base of which many bones were bare and necrotic. The edges of the ulcer, slightly raised, and quasi-cartilaginous. Histologically, epithelial ingrowths, small-celled infiltration of adjacent parts and hypertrophy of the sebaceous glands.
(2) Left orbital region, eye and nose completely destroyed, and replaced by large ulcerated cavity.
(3) Soft parts of both orbital regions, eyes, nose, forehead, and face destroyed; and replaced by large ulcerated chasm. Nearly the whole of both superior maxillæ, the nasal bones, and the anterior lamellæ of the frontal bones destroyed by the disease.

Lymphatic Glands.—In every case unaffected.

Metastases.—There were none.

The following non-cancerous diseases, &c., were found:—

Of the *Lungs.*—Old pleural adhesions over the whole of both in 2 cases (caseating tubercle of both lungs in 1 case) emphysema and bronchitis, of each 1 case.

Of the *Heart.*—Mitral fibrinous vegetations, old pericardial adhesions, atheroma of aorta, fatty degeneration and smallness, each in 1 case.

Of the *Kidneys.*—Congested in 1 case; normal in 2.

Of the *Liver.*—Congested in 1 case; nutmeg in 1; normal in 1.

Of the *Spleen.*—Small in 1; normal in 2 cases.

◆

LIQUOR HABIT CURES. (a)

By E. MACDOWELL COSGRAVE, M.D., F.R.C.P.I.,
Professor of Biology, Royal College of Surgeons, Ireland.

In the struggle for existence we are familiar with many examples of the success of some forms leading to the increase of others, often as parasites. So we find in social life that there are large numbers whose only idea of existence is to prey upon others, and who, in the struggle so to exist, have, from time to time, to turn their attention to where their wiles are [illegible] unknown, and where there is still a prospect [illegible] those shekels after which their souls hunger. Examples of this are common. The example I want to bring before your notice to-night is the way the quack medicine man has turned his attention to the victims of alcohol.

Of late years the disease element in inebriety has been more recognised by medical men, and this fact has been gradually grasped by the public, and they look to medicine to save them from the curse of inebriety. Unfortunately it is to medicine, spelt with a small m, that the public look and in this (as indeed in most cases) they disregard prevention and ask for a "cure," a real palpable, portable cure, which will fit into a bottle.

Any such demand for a "cure" is sure to be supplied, and instead of the occasional small cures which, like the poor, are always with us there has latterly been a crop of big cures, freely advertised; flotation, as large capitalled limited liability companies, being their ultimate object.

Before taking up these big cures I would like to pay a parting tribute to a small cure which has lately passed from amongst us. For years a Dublin chemist advertised and sold a strong tincture of red bark as a cure for the drink habit, and appended two testimonials to his advertisements. Years before the cure died out one of the two who wrote a testimonial of cure died, and, I merely mention the point to emphasise the value of testimonials, he died in *delirium tremens*; but long afterwards this testimonial of cure appeared in the Dublin papers.

Big cures are numerous in America—the land of big things. The Americans discovered the disease element in inebriety, and the quacks supplied them with cures; knowledge on the subject and quackery on the subject have both crossed the Atlantic to us. The profits on these big cures are so numerous that the owners can lavish money and so buy newspaper and other support. The agent of one cure told Dr. Norman Kerr (a) that they had £20,000 to develope it; that cure can get columns of advertisements put in as ordinary news in many newspapers. Even Mr. Stead who is to purify journalism was captured, and a notorious cure of this sort filled a page of his pilot balloon paper (b). *Pearson's Weekly* is at present engaged in giving a cure a huge advertisement.

Of the big cures one of the best known is that of Keeley—the gold cure, whose gold defies the researches of the analyst. Keeleyism started in America, and "institutes," where for a stiff fee inebriates could be treated, rapidly sprang up in all directions. It is needless to add that testimonials of cure poured in even during the first few days of its existence; we all have heard patients saying they were reformed, and yet have had to treat them over and over again for drink; but Keeley had the wisdom of the serpent and printed their protestations and took no notice of their backslidings.

Soon after Keeley's cure was introduced into England a meeting of social reformers was called at Exeter Hall to hear the marvels that had been done. To the credit of a member of our profession be it recorded that almost single handed he prevented the meeting from being held. It is said that circulars inviting subscriptions to "Keeley, Limited," had been printed and directed, and that if the meeting had been held they would have been delivered broadcast while the newspapers with accounts of the great meeting were being read.

The *modus operandi* of the Keeley cure is worth noticing; I give it as exposed by a medical officer to a Keeley Institute (c), C. F. Chapman, M.D.:—

(a) Read before the State Medicine Section, Royal Academy of Medicine 20th April, 1894.

(a) *Common Sense*, January, 1894, p. 2.

(b) Cf. "Review of Reviews," Xmas No., 1893.

(c) *Chicago Medical Recorder*, February, 1893.

First take the process:—Each out-patient received a hypodermic injection and a bottle of whiskey and was sent off. This was repeated day by day, and soon he refused the whiskey as the very thought of it made him sick. Then he signed a testimonial of final cure.

Next take the theory:—The "double chloride" (an unknown salt to chemists) was supposed to cure the craving for drink, and to give a real and lasting distaste for it.

Thirdly, take the explanation:—A fluid was placed in a glass, and, in the presence of the patient, a few drops of yellow solution were added. The injection was then made. But what did the fluid in the glass contain? It contained strychnia, a permanganate, and (this is the joke of the swindle) 1-10 grain apomorphia. The patient then drank his whiskey, and the apomorphia acting as an emetic it required only a few days to convince him that the whiskey was the cause of the sickness, and that his love for whiskey was turned into loathing. However when after some weeks he cautiously tried a friend's whiskey without previously having an injection he was likely to find his distaste had disappeared. However, even if that occurred his testimonial would not have disappeared and would still draw fish to the net.

There is also a Keeley Powder which can be given to a sufferer without his knowledge. I know several cases in which this was done, but none of them were cured, although some unwittingly swallowed, if not pounds *worth* at any rate quantities which *cost* pounds.

Dr. Keeley dislikes criticism and commenced an action for libel against the Medical Press and Circular which had boldly attacked these swindles, but when pressed by the defendants to go on he found that professional engagements kept him from crossing from America to an English witness box, and so he paid up costs.

The next big cure that crossed the Atlantic was exploited by Dr. Tyson, and is called Tyson's Cure. Of course, it came over armed with reports of cures from all parts of America. Indeed, so numerous do American cures seem to be that unless they relapsed new cures would have hardly any material to try themselves on! To avoid the cloud that hung over Keeleyism, Tyson claimed that his cure was purely vegetable and was not injected. The method of exploiting this cure was ingenious and cheap; the temperance party were asked to give it a better start than thousands spent in advertisements could give. In each town visited a temperance committee was to be appointed, and cases were to be treated for nothing under their supervision, and their reports, given with the guilelessness incidental to the philanthropic, were to be distributed as advertisements. This was actually done in Birmingham and Belfast, and the reports of the committees were spread broadcast, together with circulars offering treatment for £10 10s. and £15 15s. The value of these reports can easily be estimated when it is remembered that at Birmingham the committee's printed report is dated twenty-three days after treatment commenced, the Belfast test lasting about the same time. As Dr. Tyson says, "it is advisable that the patient should in every case have a sincere wish to be cured of the drink crave," and as the moral impression of the "cure" and surveillance of the committee count for something, the utter absurdity of this as a test is apparent.

Dublin was next invaded, the Birmingham and Belfast circulars being used as levers. Fortunately I was consulted on the matter, and with the powerful aid of the Medical Press and Circular was able to prevent the formation of a committee; but the struggle was a hard one. I strongly urged that the philanthropy of the so-called "cure" was simply a swindle, the one object being to get money; I also suggested that the "perfectly harmless preparation of vegetable origin," as the representative of Dr. Tyson described the cure to the Belfast Committee, probably contained strychnia. Both assertions have since been verified. By a curious coincidence on the very day that the first article appeared in the Medical Press and Circular "L. B. Tyson and Co., Limited," was registered in London with a capital of £100,000.

I believe that Dundee was next attacked, and a meeting of temperance workers and other philanthropists was called to hear the good tidings. This meeting was foiled by news arriving from across the ocean that Tyson had been prosecuted and fined for selling strychnine, and that the public analyst had testified that £10 10s. "worth" of the medicine was really value for 2s.

Still Dundee fared worse than Dublin, and some sort of a committee was made up, and on January 15th a preliminary report appeared in the papers. On Jan. 25th another public meeting was held. Next morning 2½ columns of report were given in a local paper. (a) It was headed "The Tyson Drink Cure. Second Public Test. The Committee thoroughly satisfied."

Twenty-one days had elapsed since the treatment of the earlier cases commenced, and the subjects were called upon, aided by judicious questions from Tyson's representative, to give their testimony. We read: "All the test cases had now passed the 15th day, and could be regarded as completely cured." The newspaper report would be amusing reading if it were not sad to think how cruelly the subjects and their friends will suffer when the inevitable relapses occur; and how many people misled by this report will expend, uselessly, hardly earned and ill-spared money. One subject had previously gone into an inebriates' home and had kept her pledge after coming out for a fortnight; then she "got it from some of her friends"; but the committee seemed satisfied that she would not relapse after their treatment. After the usual vote of thanks, Dr. Tyson's representative warned them that "they must expect an occasional little relapse," and the meeting broke up cheerfully.

Since that Dr. Tyson has come over to protect his interests: a long report in a Belfast paper represents him as saying that the Australian analyst who stated he had found strychnine was in error, but that he had marked his medicine "poison" in Australia. He said the medicine contained brucine, and gave the usual account of how he suddenly thought of it.

I have occupied the time of the Section with these "cures" in order to enlist the sympathies of those present in the effort to expose and put down these frauds. The way in which the vendors of quack medicine are allowed to impose on the credulity of the public is shameful. It would not be so bad if only the rich were fleeced, but too often the needy are the victims; the inebriate's money is seldom plenty, and the extraction of 10 or 15 guinea fees too often means some suffering and even debt for the relatives. The personal influence of Father Mathew, without fee or medicine, caused 2,000,000 Irish to take the pledge and to keep it for a time, but only a decimal percentage remained true when the period of excitement was over. The idea of Government guarantee suggested by the word "Patent" should be got rid of, and Government should publish analyses and approximate money value of proprietary medicines; but it is of what lies in our power I want to speak. One way in which we can do good is by letting it be known that, whilst inebriety is to a great extent a disease, it is not a disease which any specific can cure. Typhus used to rage in our city, and would still be raging if nothing had been done but look for a cure. Improved hygiene has changed it from a common into a rare disease. Just so must it be with inebriety. Improved knowledge and better teaching will in time render it less common. In the meantime, the rational method of treatment of the inebriate is to enforce absolute abstinence and to try and build up the system to a condition of health. If the inebriate has enough moral strength to avoid the countless temptations to drink, there is good hope of permanent cure, but if the will-power be so weakened that in spite of knowing the evil that drink is doing him and desiring to be cured, he is not able to withstand temptation, but drinks when asked, the only reasonable hope of cure is detention in an inebriate asylum where drink cannot be obtained. Even then it too often happens that a year's detention builds up self-confidence out of proportion to real strength of will, and those discharged fall victims to their friends who urge that surely they can now take a little with safety.

(a) *Dundee Advertiser*, Jan. 26, 1894.

An inebriates' home presents, however, some prospects of cure, and many cases have remained cured for years after leaving. What hope is there, however, for those treated by one of these quack cures. The two shillingsworth of strychnine lasts some twenty-one days. During that time, there is a moral impression made, the idea that it is a cure is impressed on the imagination, and the ten or fifteen guineas paid enhances this effect. The friends too are all on the side of the cure, they help for the stated time. But after the "cure" is completed, when the testimonial of cure has been drawn up and signed, what chance is there of permanence. Little, if any. The very things that help at first, hinder in the end. The self-confidence that strengthens at first, ruins at last. Friends crowd round and say. "You are cured, surely you will never again drink to excess, take a little," and feeling sure of being cured, he does take a little, and in a few days he is where he was, his friends have suffered a bitter disappointment, and the proprietor of the cure has ten or fifteen guineas and a testimonial.

I have seen a good many efforts to reform, many unsuccessful but some successful. Of the successful, all remained abstainers. I cannot remember a single instance in which an inebriate turned into a moderate drinker.

Quackery is most rampant where medical men least care to treat. Inebriates are not a very hopeful class, but they are not a hopeless one, and if medical men took more interest in their treatment, inebriety would be sensibly lessened, and the big cures now booming would return to their former small insignificance.

Selected Prescriptions and Therapeutic Notes.

121.—Neebe's Treatment of Sweating Feet by Crude Hydrochloric Acid :—

When the feet are very tender, especially in hot weather, treatment is preceded by an eight to ten days' application of compound talc powder, which is sprinkled in the stockings. The application of the acid is best made in the evening. The crude hydrochloric acid is poured into a flat vessel of stone or glass or porcelain, sufficiently large to receive the two feet. Since the soles of the feet and the skin between the toes are the seat of the trouble, sufficient hydrochloric acid is poured in the vessel to completely cover the soles. It should not be allowed to come in contact with the skin of the back of the feet. The heel is kept in the acid for five minutes ; then the sole of the foot for ten minutes. After this the feet, especially the skin between the toes, are washed in soap and warm water. Soaking in the acid must be at once stopped as soon as pain is excited, and the painful spots must be treated with zinc ointment until healing is complete. The process of soaking may be repeated twice weekly, and continued for from five to eight weeks in obstinate cases.

122.—In Cases of Anæmia :—

℞ Ferri reducis ;
Pulv. camphoræ, āā ʒjss ;
Ext. gentianæ, ʒj ;
Mucilaginis acaciæ, q.s.

M. To make ninety pills. Two or three may be taken thrice daily.—Edlefsen.

123.—A New Treatment for Pertussis :—

℞ Hydrarg. perchlor., gr. j ;
Aq. destill. ad ℥iv.

M. For external use.

A small tampon of cotton wool is dipped in the solution and then the base of the tongue, the epiglottis and the mucous surfaces adjoining are freely swabbed therewith. In slight cases of pertussis this treatment may be practised once a day, but in grave cases twice in twenty-four hours.—J. Ranbitschek

124.—A Useful Hepatic Stimulant :—

℞ Euonymin, gr. ij ;
Pil, col. c. hyoscyami, gr. ij.

M. To form one pill—one or two to be taken at bedtime.

125.—For Hæmoptysis :—

℞ Pulv. ergotæ ;
Pulv. extracti krameriæ, āā ʒj ;
Extracti belladonnæ, gr. v ;
Pulv. digitalis, gr. x.

M. To make forty pills. From four to six to be taken for a dose. The patient must keep quiet, lying in bed with heat to the extremities, and be given pieces of ice to suck.—De Mousey.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, April 27th.

The President, Mr. Hulke, in the Chair.

Dr. Habershon showed a barmaid, æt. 22, suffering from amnesia with right hemiplegia. At the age of 16 she became very anæmic and consequent on a fright she developed marked hysteria. In 1893 she fell down and apparently lost consciousness, on recovering which she was unable to speak. At the present time there was partial amnesia which seemed to be a residuum of the previous attack. He expressed an opinion that there was probably an actual lesion of the nature of thrombosis complicated by functional manifestations.

Dr. Hale White showed a man with muscular dystrophy. The patient was 22 years of age. When 8 years old he had an illness of obscure nature which kept him in bed for some weeks, after which he found himself unable to walk. As shown, he was suffering from atrophy of most muscles of the body, the only muscles not affected being the infraspinati and the muscles of the abdomen and hip. The bones had ceased to grow probably in consequence of their lacking the "muscular stimulus" to development.

Dr. R. J. H. Scott showed a man, æt. 35, who was thrown from a horse 14 years ago, bruising his leg. This was followed three years later by the development of a popliteal aneurism, and his femoral artery was tied at St. George's Hospital. The tumour shrank, but three years ago it again began to increase in size. In June, 1893, while running, he had a sudden pain in the calf of his leg and two days later signs of gangrene manifested themselves in the foot, due to embolism from the aneurism lodging in the posterior tibial artery. The aneurism was cut down upon, the popliteal artery ligatured above and below, and the sac dissected out, Chopart's amputation of the foot being performed.

Dr. Rose Bradford showed a girl, æt. 15, with facial hemiatrophy. She had complained of neuralgic pains on the left side of the face in September last, and this was followed by wasting confined to the area corresponding to the upper maxilla, and most marked in the subcutaneous tissue. There was doubtful optic neuritis. Sensation was not markedly interfered with, and there was no wasting of the tongue.

Dr. **Walter Carr** showed a lad of 11, suffering from peripheral neuritis (?). In October last he complained of severe pain and tingling in the hands and feet, and remained in bed for a month. Later on complete and symmetrical paralysis of both hands and feet supervened. Sensation was not affected. No tenderness was noticed over the nerve trunks. The diagnosis lay between peripheral neuritis and acute anterior polio-myelitis.

Dr. **Cayley** showed a lad of 12, who after an attack of articular rheumatism, developed multiple fibrous cutaneous nodules like *erythema elevator diutinum*, of Croker. Microscopical examination of a nodule showed it to be composed of fibrous tissue.

Mr. F. **Eve** showed a case of "black tongue" in a man, æt. 64. He alluded to Raynaud's view as to the fungoid nature of the affection and added that experiments were in progress in this direction.

Mr. **Eve** also showed a child, æt. 3 months, with a meningocele over the posterior fontanelle.

A MODE OF MAKING EXTENSION IN FRACTURES OF THE THIGH.

Mr. **Richard Barwell** explained that he had devised this method as far back as 1860 for use in hip disease. The apparatus consisted of an ordinary Liston or Desault splint, long enough to reach from the axilla to three or four inches below the foot. To each prong of the fork at the lower end metal arms were screwed, so that these, coming together, supported below the centre of the sole, a pulley, half an inch in diameter at the flange. At the angle of the gap between the two prongs there was another pulley merely to prevent friction. Quite at the upper end and projecting about an inch from the outer surface of the splint was a third, rather larger, pulley. To use this apparatus a strap, two inches broad, of adhesive plaster on strong calico, is applied to the limb so that the ends are just below the knee on the inner and the outer side, while the centre forms a loop below the sole. A piece of strong catgut is attached to the centre of this loop, passing thence downwards under the first-named pulley, thence upwards over the pulley at the angle of the fork, and terminating short of the centre of the splint on its outer aspect. Turning to the upper end of the splint, a perineal band is applied, preferably to the sound side, though on the present occasion he demonstrated it as applied on the fractured side. This band includes both limb and splint, its ends, where stitched together, being some little distance below the above-described third pulley. Here a piece of catgut is attached, which, passing at first upwards through the pulley, changes its direction and runs thence downwards towards the catgut which is fastened to the foot. They both, however, stop short of meeting, and to the upper piece a length of brass chain is fastened, and to the lower one an inch of rubber accumulator with a hook attached which, being hitched into any one link of the chain, determines and preserves any required degree of tension on the india-rubber spring. The splint is now secured by a broad girth and a few laps of roller to the limb. The special value of the appliance lay in the constancy of the force and in the uniformity of direction.

The **President** observed that the appliance presented several points of resemblance with De Morgan's splint, and said it was, moreover, open to the objection that applied to this as to Liston's splint, viz., that it did not prevent the rotation of the limb on its long axis, a complication which there were several ways of overcoming.

Mr. **Barwell** pointed out that he had invented this splint 34 years ago so that he could not be accused of copying De Morgan's splint. Axial rotation was prevented by sand bags which could easily be applied and did not, as when applied in weight extension, interfere with the extending force.

Dr. L. **Brunton** and Mr. **Cheyne** on a case of

INTESTINAL OBSTRUCTION DUE TO CONSTRICTION OF THE BOWEL AFTER APPENDICITIS.

The case was that of a man, æt. 35, who had suffered from attacks of appendicitis for some years. Thirteen days before the operation described he was seized with sudden acute griping pain in the abdomen, the attack lasting about an hour and then passing off. Similar attacks occurred at varying but frequent intervals, the bowels being, however, open, though only imperfectly. Thirty-six hours before the operation he took a dose of castor oil, which set up intense pain, and was followed by complete obstruction, and about twenty hours afterwards by extreme collapse. About 30 hours after the castor oil he had fæcal vomiting, and when put on the table he was practically moribund, and his pulse could not be felt. The diagnosis was a narrowing of the bowel from the gradual contraction of fibrous tissue resulting from the repeated inflammatory attacks, and this was found to be correct on operating. The abdomen was opened, the appendix which encircled the ileo-cæcal valve removed, and the adhesions cut and torn through till the contents of the small intestine could be readily squeezed into the large. After the operation, during which ether was administered, the pulse could be felt. He lay in a collapsed, almost pulseless condition, for about 30 hours after the operation, without vomiting, however, and without any marked pain, and then he had two copious and very offensive stools. After that he was very collapsed, but soon recovered, and when seen 36 hours after the operation, his pulse had greatly improved. His subsequent recovery was uninterrupted, and he remains well. The points of interest in the case were the diagnosis, the treatment, and the collapsed state of the patient. The chief difficulty in diagnosis was from internal strangulation, but the history of the case and the general symptoms seemed to point conclusively to constriction of the bowel, as was found on operation. The complete success following division of the adhesions is of great interest from the fact that this condition is generally irremediable after localised peritonitis, on account of its extent and the injury to the bowel wall which usually follows attempts at separation of these adhesions. The collapsed condition of the patient was clearly due to septic intoxication from absorption of poisonous materials from the intestine, and affords strong evidence of the view held by some that a considerable amount of the trouble after strangulated hernia is often due to similar absorption.

ANOTHER CASE OF ACUTE OBSTRUCTION.

Mr. A. **Quarry Silcock** related the case of a patient, a man, æt. 26, who was admitted to St. Mary's Hospital on September 26th, 1893, suffering from acute intestinal obstruction and peritonitis. The intestines were greatly distended, the abdomen generally being tender, and the vomiting frequent, the ejecta having a fæcal odour. He was seen shortly after admission by Dr. Luff, who deemed an exploration necessary. On opening the abdomen in the middle line below the umbilicus a small quantity of turbid serum escaped. The vascularity of the adhesion precluded any systematic search for the possible source of obstruction. The man's condition at this point became so alarming that the operation was abandoned, the wound being hastily stitched up and the man removed to the ward. The next morning he had recovered from the extreme collapse, and he opened up the central part of the wound, and made a small incision into a prominent coil of small intestine, and through this incicision he thrust the cannula of a suction trocar furnished with a long indiarubber tube leading to a basin below the bed. This was held in position for 4½ hours by relays of dressers, and a large quantity of fluid intestinal contents came away to the evident relief of the patient. The vomiting and hiccough ceased, and the pain was reduced. After the withdrawal of the cannula the wound in the intestine was closed, but it subsequently reopened emitting much fluid intestinal contents. From the character of the latter it was judged that the ileum had been tapped. On September 30 he passed a motion per rectum, and by October 9 the intestinal fistula had closed. He was discharged cured on November 8th. The cause of the peritonitis was unknown. The patient had had no trouble with his bowels since his discharge.

Dr. **Lauder Brunton** mentioned that the patient was evidently suffering from impending paralysis of the respiratory centre, and he injected strychnine solution drop by drop until the desired effect was produced The vomiting was described as stercoraceous, but on examination, it did not prove to contain any fæcal matter. The striking point was the the extreme depression of the patient, who really appeared to be *in articulo mortis.*

Mr. **Golding Bird** observed that it was curious obstruction from appendicitis should be so rare, considering how commonly one met with affections of the appendix. He recalled the case of a man, æt. 30, who came in last December with a history of having had fifteen attacks of pain, &c., in the right iliac region associated with local distension and the formation of a tumour the size of an orange in that situation. This generally disappeared coincidently with the discharge of pus in the stools, pointing to suppurating appendicitis. This tumour, however, had not disappeared after the last attacks, and when Mr. Durham examined it he came to the conclusion, from its feel, that it was a neoplasm. He had cut down upon it to relieve the obstruction, and found the caput cæcum coli of an hourglass shape, the appendix being reduced to a mere thread adherent along the cæcum. He tore through the adhesions and closed the wound, and since that time the man, who made a good recovery, has been perfectly free from pain or inconvenience of any kind.

Mr. **Eve** pointed out that cocaine could often be used in these operations to the exclusion of a general anæsthetic. In the case of a patient who appeared to be *in extremis* he had made use of 30 drops of a 2 per cent. solution of cocaine with perfectly satisfactory results.

Dr. **Hale White** recalled the case of a woman with empyema secondary to sub-diaphragmatic abscess, who seemed on the point of death. She was aspirated and pus with a fæcal odour withdrawn, after which she rallied and lived for three days. He suggested that the improvement was probably due to withdrawal of the toxin-producing pus.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Medicine.

Meeting held Friday, April 6th.

Dr. Grimshaw in the Chair.

NOTE ON AN ATAXIC CASE (PATIENT EXHIBITED).

Dr. H. C. **Tweedy** exhibited a case presenting some remarkable nervous symptoms—viz., spastic ataxia of the lower limbs on attempting to walk, though the legs could be moved in any direction when the patient was lying down or sitting. There was also partial anæsthesia and paresis on the right side of the body and slight tremors of the head and right hand. The internal rectus muscle of the left eye was paralysed, and there was marked nystagmus. The patient had complete anosmia, scanning articulation and loss of taste on left side of the tongue. On the other hand, the cutaneous, periosteal, and deep reflexes were normal. There was no defect in accommodation, no optic neuritis, no headache, vertigo, vomiting, nor pain of any kind, and no trophic disturbances. The patient was twenty-three years of age, and had been three years in the Royal Irish Constabulary, and up to December, 1893, had enjoyed perfect health, from which time the symptoms described had come on gradually. He confessed that he had been in the habit of practising masturbation for several years. Dr. Tweedy gave it as his opinion that the case was one of insular sclerosis, basing his diagnosis on the age of the patient, the nystagmus, the peculiarity of articulation, and the spastic movements of the legs. At the same time he admitted that the history of masturbation rendered it possible that the symptoms were functional.

Dr. **Doyle** suggested that the man, perhaps, might be a malingerer. He recalled a case exhibited at the Academy some years ago of a patient in adult life, and supposed to be suffering from "chronic chorea." It turned out that the patient had been under treatment before and had learned the symptoms well. He proved to be a malingerer.

Dr. **Burgess** said he did not take Dr. Doyle's view of the case, and he thought the most interesting part of the case to be as to whether the disease was functional or organic. If it were functional it would probably get well after some time. He thought that very likely it was due to masturbation.

The **Chairman** narrated the history of a case he had seen in consultation many years ago. The patient was an athletic youth of nineteen, who had become partially paraplegic, and whose body used to be usually inclined to one side. There was thought to be something unusual in the appearances of the spinous processes, and the patient had an apparatus made for him, and was kept fairly quiet. He got quite well. Ten years afterwards he told him that he masturbated at that time, that he gave it up and recovered.

Dr. **Tweedy**, in reply to Dr. Doyle, said that he had no ground whatsoever for supposing this man to be a malingerer. As regards Dr. Burgess' view of it possibly being a functional disorder, the fact that he had not improved at all during the past month was against it.

TETANY.

Dr. **Alfred Parsons** read a clinical note on a case of tetany which occurred in a schoolboy, æt. 14. For the past three or four years the patient had occasional attacks of tingling and pins and needles in his forearms and hands. Each attack lasted some twenty seconds, and he has had six or eight attacks in twenty-four hours; but till quite recently they were never followed by spasmodic contractures. On March 1st he was suddenly seized with tingling in the forearms, followed by rigidity of the extremities. The lower limbs were extended, the feet being somewhat inverted. The arms were flexed at elbows, the wrists flexed, thumb flexed and adducted; the fingers were flexed at the metacarpophalangeal joints, but extended at the other joint. There was flushing of face, and anterior aspect of trunk; profuse perspiration; very frequent action of heart; slight elevation of temperature (99° F.) The spasm in legs lasted a few hours, in arms a few days. The latter exhibited Trousseau's phenomenon on several occasions, but the Schultze-Choostek reaction could not be obtained in the arms or face. The exalted electrical irritability described by Erb was not looked for. The boy returned to his schoolwork after four or five days, and since that only one similar, though less severe, attack has manifested itself. This seems to be the first case of tetany recorded in Ireland.

Dr. **Burgess** mentioned a case presenting somewhat similar symptoms to that of Dr. Parsons. In him, however, the convulsions were more general. The patient, in the absence of the doctor who attended him, was treated by another practitioner, who, taking a different view of the case, gave him a dose of turpentine and castor oil. He passed a large tapeworm and got quite well.

Dr. **Dawson** said that cases of tetany occurred most frequently in shoemakers and next so in tailors. It did not occur among female shoemakers. It was also liable to occur in women at the fifth month of pregnancy if this coincided with the season of the year at which it was prevalent. Sometimes it was associated with epilepsy and sometimes with cataract. The latter was supposed to indicate a very severe attack of the disease.

Dr. **Parsons** briefly replied, and the Section then adjourned.

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, April 19th.

The President, Mr. George Eastes, in the Chair.

Dr. **James Taylor** gave a lantern demonstration on

POINTS OF CLINICAL INTEREST IN DISEASES OF THE NERVOUS SYSTEM,

showing about 40 photographs of patients, of macroscopic and microscopic preparations.

The **President** in the name of the Society thanked Dr. Taylor for his most interesting and instructive demonstration. He asked Dr. Taylor what his opinion was with regard to the presence or absence of optic neuritis in diagnosing the locality of an intra-cranial tumour.

Mr. **Sutherland** asked Dr. Taylor some questions as to the forms of muscular atrophy—not due to spinal lesions.

Dr. **Winslow Hall** adduced as proof of the value of the demonstration, that one set of photographs shed great light on a nervous case which had long puzzled him, and asked him for further information about the affection in question—Muscular Dystrophy of Erb.

Mr. **Peyton Beale** remarked upon the photographs shown by Dr. Taylor of degenerations of certain "white" tracts in the cord. He was anxious to know how the specimens were stained. He had never seen the degenerated parts shown so distinctly before by any method.

Dr. **James Taylor**, in reply to the President's question, said that it was very difficult to formulate any rule as to the occurrence of optic neuritis in cases of cerebral tumours. From his own experience he would be inclined to say that when the tumour was in the cerebellum, optic neuritis was almost invariably present, when it was confined to the pons or medulla, especially if of the infiltrating variety, it was more often absent than present, and when it was in the hemispheres sometimes it was present and sometimes absent. A large tumour might not cause neuritis and on the other hand a severe neuritis might exist with any small growth. The rapidity of growth of an intracranial tumour seemed to be an important element in the production of neuritis, and he himself was inclined to think that the increased intra-cranial pressure had a very close causal relation to the optic neuritis. In reply to questions from Drs. W. Hall and Sutherland he expressed the opinion that it was much better to term all these cases of muscular hypertrophy, for Erb had recently shown that the three usual forms pseudo-hypertrophic paralysis, idiopathic muscular atrophy, and the facio-scapula-humoral or Landouzy-Deperine type, were all varieties of one disease, different forms occurring in members of the same family and even in the same patient at different times. In reply to Mr. Beale, he said that the Weigert-Pal was very suitable for specimens such as he had shown. The Marchi method being more adapted for conditions in which the degeneration had only lasted a short time.

Paris, April 28th.

Icterus.

Dr. Ferrand, of the Hotel Dieu Hospital, gave recently an interesting clinical lecture on Icterus and its treatment, of which I transcribe a summary :—

Icterus is produed by the absorption of biliary pigments ; these pigments are not only invested with chromogenic, but also with toxic properties, and are capable of injuring the tissues of their region. The *rôle* of these pigmentary substances is most important as, where they are not toxic, they singularly aggravate certain maladies. Jaundice can be divided into two great classes : jaundice from retention and jaundice from biliary flux. The former is produced each time that an obstruction is produced in the biliary ducts ; the bile is absorbed by the numerous lymphatics, and is not slow to pass into the blood current, producing generally toxic phenomena.

The jaundice in such cases is always of a dark colour, somewhat like bronze, such as is observed in cancer of the liver, and in those affections where the biliary duct is obstructed. The pigment is found in the urine by the test of Gmelin, it is found also in the serum, but it is entirely absent in the fæces.

Jaundice from exaggeration of the flux is not always the result of an increase of the biliary secretion ; it can simply derive from, as shown by Stadelmann, a superabundance of the pigment in a normal quantity of the bile. It is, in a word, a bile highly coloured, and is absorbed into the system, but the colouration of the skin is lighter, and bile is found in abundance in the fæces.

The biliary pigment is, in the normal condition, composed of a particular substance, which has been called bilirubine. It can be decomposed by oxydation into three distinct elements : biliverdine, bilinianic, and bilipurpurine. These last substances colour certain infantile diarrhœas. Decomposition by reduction gives rise to the formation of urobiline, but between the urobiline and the bilirubine is found a series of pathological products ill-defined but classed under the name of *brown pigment*.

As to the origin of these pigments, it has been fully demonstrated that they are derived from the blood, and more particularly from the hemoglobine. But this latter has to pass through a series of modifications—hematine, hematoidine—before producing the biliary pigment. When once formed the pigment passes into the biliary ducts, and from there into the intestine, where it plays an important *rôle* in digestion.

What becomes of it in case of jaundice ? We have just seen how the bilirubine passes into the blood, and from thence into the tissues ; we know also that by reduction, urobiline is produced. This reduction can take place in the blood (Tissier) or in the tissues, or even in the kidneys (Mya). But urobiline is also frequently produced in the hepatic cell, when this latter is diseased, consequently the two elements of which account must be taken in order to understand the pathology of hemapheic icterus is the blood and the hepatic cell. The blood is either primarily or secondarily affected, and the hemoglobine, which has such a natural affinity for oxygen, is diminished. For this reason inhalations of oxygen have been recommended in certain forms of icterus as well as ether and turpentine, essences apt to favour oxidation. As regards the liver, the therapeutic agents are numerous. In the first case the organ is generally congested, and this condition must be modified by revulsives, frictions, actual cautery, &c. Where the jaundice is due to polycholia, agents producing a moderating effect on the biliary secretion must be prescribed, such as milk diet, frictions, diuretics, and sudorifics.

Where the icterus is due to retention, means should be taken to re-establish the flow of bile, and we have here two kinds of therapeutic agents : general eliminators and special eliminators. To the first class belong acetate of ammoniac, ether, and turpentine ; to the second, bicarbonate of soda (a drachm daily) iodide of potassium as an alterant and phosphate of soda as a purgative. Vichy or other alkaline waters are also useful in such cases.

Before I conclude allow me to mention one other agent which you have seen me frequently use and that is glycerine. Given at the dose of one tablespoonful in the morning fasting, it has produced most beneficial results. As a *régime*, a vegetable diet alone should be allowed to the patient.

Germany.

[From our own Correspondent.]

Berlin, April 27th.

Supra-Renal Tumour.

Lazarus showed a preparation before the Gesellschaft taken from a child, æt. 3½, which had been received into hospital in the middle of February. According to the mother's story the disease commenced with pain in the body, which soon began to swell. In the right upper part of the abdomen a firm hard swelling was found which was taken for disease of the liver. The lungs, heart, and kidneys appeared to be healthy ; the child became feeble and pale, the hemoglobine of the blood 50 per cent., and at no time in the history of the case was there fever. Repeated punctures from the margin of the ribs to the umbilicus over the region of the swelling emitted very little fluid, of which the microscopical examination gave no confirmation of a malignant character. Closer diagnosis revealed a renal tumour. The child rapidly emaciated, while the weight of the body as quickly increased, till, eight days after admission, it died. On section the abdomen was found to be filled with a tumour; the total weight of the child was 37 lbs., the tumour alone 12 lbs., which originated from the left supra-renal body, which was firmly adherent to the cortical surface of the kidney. The small bowel was pressed upwards and backwards, stomach and large intestine were crushed into a small space on the right side of the diaphragm. During life no discolouration of the skin was present. Over the surface of the tumour small nodules were found rising in knots, which on examination proved to be sarcomatous degeneration. The liver appeared as a sheet of paper enveloping the tumour.

Syphilis and Tabes.

Grimm read a paper on the origin of tabes and its frequency in syphilis. Recently opinions have varied concerning syphilis being the origin of several diseases. Some have gone so far as to accuse the mercurial treatment as the origin of many diseases. Grimm's experience goes to show that a heavy percentage of tabes is due to syphilis. During his seven years of active service in the hospital in the Island of Jesso, where syphilis is rampant, tabes dorsalis was very common, and in the summer time 5 to 10 per cent. of the whole population suffered from beri-beri, with patella reflex and paresthæsia of the extremities. During five of his years' residence the average reception of patients was 10,000 to 13,000 patients, of whom not less than 10 per cent. were syphilitic. 9,800 came under his own observation. 1,271 of these suffered from eye disease, 180 of interstitial keratitis, the sufferers being mostly of the congenital type; 26 were accompanied with iritis; 29 with amblyopia without any striking changes in the fundus, but undeniable evidence of syphilis elsewhere. From an analysis of 400,000 affected with syphilis the greater number were found to be fishermen, the second dwellers in towns, and the least country people. The glandular diagnosis in the Japanese is much easier than other nations, owing to the absence of panniculus adiposus. Syphilitic treatment is a thing almost unknown, which allows the disease to run its course, giving rise to the gummi swellings and the disturbance in the mucous membrane. In small communities where syphilis is present there is a greater probability of estimating the number, because tabes dorsalis is an affection that relief will be sought for. His experience on the coast line, where syphilis is more prevalent, from statistics he found out of 694 cases 63 syphilitic, and from this number he was surprised to discover only 5 cases of tabes dorsalis which could not be clearly proved to originate from syphilis. Anti-syphilitic treatment, on the other hand, could not be accused, as this was unknown. The diseases of the nervous system probably syphilitic were not uncommon, but the relationship of tabes according to statistics were insignificant.

The Royal University of Ireland.

The second examination in Medicine commenced yesterday, and the examination for the degrees of M.B., B.Ch., B.A.Q., to-day, is proceeding.

Austria.

[From our own correspondent.]

Vienna, April 27th.

Arcus Senilis.

Prof. Fuchs brought forward a young boy, who recently consulted him for xanathelasma in both eyes. This is a condition not uncommon in advanced years, but rarely found as congenital as seen in this case. The band was thinner above than on the sides and below and measured a mm. in breadth. This advanced condition would resemble a case of forty years of age, but in the senile the morbid conditions commence above and below, the two crescents meeting on the sides which is somewhat different in the case he showed. In this case the arc is more saturated than in the senile. He related a similar condition which he once saw in a case, æt. 18.

He is inclined to differ from the accepted orthodox opinion that this morbid change is due to a deposit of fatty substance, and considers it as a deposit of hyaline substance or pinguecula. Hyaline is an insoluble albuminoid, and may be gradually deposited on the metabolic conditions being reduced. He attempted to prove this by the fact of young people having the limbus being succulent and richer in blood vessels than the aged, which presumably would nearly induce an atrophic or lower state of nutrition. The cornea also in elderly people becomes thinner. A similar condition in the eye is sometimes observed where an atrophic condition of the limbis is present, and this pathological condition is not unfrequently met with in the form of a yellowish brown neoplasm in the limbus after infantile catarrhs, which may be a fruitful source of premature senile conditions. He recorded the state of another young man who had the arcus senilis on both cornea, and had suffered frequently in early childhood from repeated catarrhs.

Prof. Mauthner related the case of a young man who had a similar arcus senilis as that shown by Fuchs which had existed from childhood. The nature of the morbid condition he would not pause to discuss, but was inclined to believe that it was analogous *in fœtu* to that of advanced life.

Prof. Neuman said that there was to be found in the cuticle tissues fatty degeneration, cartilaginous deposits and hyaline changes in the later stages of life; the elastic fibres were also observed to become fibrous. The older the individual, the greater the anatomical changes were found.

Prof. Gruber said that in old people, and rarely in the young, he found yellow patches in the tympanum. These were generally recognised as fatty changes. The hyaline substance advanced by Fuchs was novel and might be worthy of consideration.

Progressive Muscular Atrophy.

Limbeck next showed a man, æt. 52, who suffered for nearly eight years with weakness of the upper extremities progressing so rapidly at the beginning that the limbs were perfectly powerless in a few weeks. No hereditary taint can be elicited; intelligence, speech and all the cerebral organs seem to be intact, and no albumen to be found in the urine. The most striking feature is the deformity of the shoulders, both the acromial portions being lower than the sternal; the shoulder blade hanging winglike and the patient unable to raise the arm to the horizontal. The fibres of the serratus anticus major, pectoralis, muscular obliquus abdominus are quite gone, while the shoulder can be passively moved even to the muscles of the ear. The deltoid, muscles of the forearm and small muscles of the hand remain well developed. Triceps very feeble, and muscles of the extremities quite powerless; slight lordosis in the lumbar region, sensibility quite normal, quantitative electric stimuli altered, and the muscles of the face still retain their normal appearance. The microscopic examination showed hypertrophy of the deltoid with fatty degeneration of the biceps. He considered this a classic case of progressive muscular atrophy.

Sycosis Parasitaria.

Spiegler showed a man with abscesses on the skin which apparently were undermined by the parasite trichophyton tonsurans. The application of carbolic or sublimate was effectual in reducing the disorder. On this he remarked that the disease was common amongst country people who were more exposed or brought into closer contact with animals, from which it was evidently transmitted. Residents in large towns were seldom affected. Prof. Neuman remarked that this was nothing more than herpes of the face. The parasite can establish itself in different parts of the body. Twenty years ago Hebra could not find a single case of this kind although at the present time it is not infrequently met with.

◆

The Operating Theatres.

ST. MARY'S HOSPITAL.

Umbilical Hernia.—Mr. Owen operated upon a stout middle-aged woman for an irreducible umbilical hernia, somewhat larger than a fist. He made a crescentic incision through the fat-laden superficial fascia at a little distance on either side of the base of the tumour, and continued these incisions through the aponeurosis of the external oblique and the peritoneum. He then bodily lifted up the sac and its contents, and, having separated and tied the pieces of omentum entering the sac, he cut them off. He then adjusted the edges of the peritoneum, and those of the abdominal wall by silk sutures, and dressed the wound with a pad of wood-wool. He remarked that he preferred this method of operating to that of opening the sac and then dealing with its contents, as it rendered the procedure more simple and straightforward.

KING'S COLLEGE HOSPITAL.

Amputation of the Hip-Joint by Furneaux Jordan's Method.—Mr. Rose removed the right lower extremity at the hip-joint by a modification of Furneaux Jordan's method, amputating first through the upper part of the femur and then removing the remainder of the bone with its head. The patient, a young man, æt. 20, had already five years previously been operated on by the same surgeon for mischief in the hip; and had always experienced bad health, having had rheumatic fever when a child, and subsequently albumen in the urine; at the time of the first operation there were abscesses about the joint; since then there had been 2½-inch of shortening in the limb, sinuses had remained discharging considerably, the albumen still persisted; there was no sign of pus in the urine. Mr. Rose said that as there was amyloid disease of both kidneys and of the liver the patient was not in a condition to stand the strain of excision of the hip with an exposed section of bone with sinuses, inasmuch as septic sinuses already existed; the limb was quite useless, the patient being unable to bear the weight of the body on the shortened extremity, therefore he thought that amputation of the hip-joint gave the best chance of life. During the operation he remarked that there were evidently amyloid changes in the vessels, causing thickening of their coats. There was considerable hæmorrhage from the smaller vessels. The femoral artery was secured when cut. The side of the pelvis was bare and was freely scraped. The globular head of the femur was found to have disappeared and the neck of the bone to be covered by dense fibrous tissue. The acetabulum was drained by a tube.

Melanotic Sarcoma.—Mr. Carless dealt with a case of melanotic sarcoma of the abdominal wall in a woman, æt. 54. The primary mass was situated mid-way between the ensiform appendix and the umbilicus a little to the left of the middle line, and had been growing for two years. The axillary lymphatic glands were distinctly enlarged, two masses nearly as large as pigeon's eggs were evident. Moreover, there were several small cutaneous patches below and to the inner side of the left mamma, lying in the course of the lymphatic vessels, and evidently due to lymphatic infection. Mr. Carless pointed out before operating that in such a case where secondary deposits were already present in the glands he could hardly hope to save life, but considered that possibly life might be prolonged by removing the main external foci of disease. The general health had been remarkably good, and at any rate it seemed justifiable to attempt to eradicate the growths. He also pointed out that the only chance of success lay in a very thorough removal, and hence proposed not only to take away the primary mass and the axillary glands but also the strip of thin subcutaneous tissue extending between them including the small cutaneous secondary nodules. This he proceeded to do by two long incisions quite two inches apart united above and below. The whole of the subcutaneous fat down to the deep fascia was included in this dissection. The axilla was now freely opened by an incision along the lower border of the pectoralis major, and the fatty and glandular contents removed, a proceeding which necessitated the exposure of the axillary vessels. The wound was closed by a continuous suture, and subsequently found by measurement to be about 16 inches in length; provision was made for drainage from the axillary cavity. It is satisfactory to state that a week after the patient was nearly well, and the wound practically healed by first intention.

ST. THOMAS'S HOSPITAL.

Operation for Weak Abdominal Wall and for Varicocele.—Mr. Battle operated on a young man, æt. about 17, who had been rejected for the army on account of "rupture." On examination this was found to be a bulging in the abdominal wall on the right side at the position of the internal abdominal ring, there being no real hernia. This condition was limited to the right side. He had no pain, and did not know that there was anything wrong with him until told so by the examining medical officer. He was also the subject of a varicocele on the left side. The operation consisted in making an incision along the line of the canal to expose the external oblique; this was then divided on a director and the neighbourhood of the internal ring fully exposed to view; the ring was large and its muscular boundary thinned. Sutures were passed from above downwards so as to bring the muscular margins closely together over the bulging peritoneum and subperitoneal tissue. The opening in the external oblique was then closed, the lower margin being drawn upwards and secured to the upper layer of the muscle at about an inch from its edge; the upper margin being fastened to the lower part of the muscle where it most easily came by means of interrupted sutures; by this means a very strong barrier was provided against any future projection of abdominal contents. The wound was closed without drainage tube and dressed in the usual way. Mr. Battle then operated on the varicocele on the left side in the manner previously described in "Operating Theatres."

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 2, 1894.

RHEUMATISM AND ELECTRICAL RAILWAYS.

THE gradual development of applied electricity has placed at the disposal of engineers that most wonderful modern method of transit, the electrical railway. This form of travelling is of especial value in the case of crowded centres of population, where the necessities of the situation have compelled the railway companies to burrow underground, and to construct, as in the metropolis, an undermining network of tunnels. Electricity has the great advantage over steam that it can be applied as a motive power without the fouling of the air by soot, carbonic acid, and sulphurous fumes which results from coal-fed locomotives. Hence, from a hygienic point of view, it is most desirous to substitute electrical engines for those at present in use. But there are other standpoints, apart from the sanitary or the æsthetic, which lend new and unexpected aspects to the case. For instance, we find a distinct therapeutic value attached in many quarters to the simple fact of travelling in an electrical railway carriage. In some way or other it has become a fixed article of popular belief that rheumatism may be cured in this way. Indeed, a circumstantial tale is going the round of the journals about a guard who had been for many years a martyr to rheumatism while in the service of one of the large companies, but who has never had a touch of the malady since he went to work on an electrical railway. The story is a pretty one, so far as it goes, but we regret to say it will not bear the test of a moment's critical examination. For instance, it is a pure assumption that persons travelling in an electrical railway carriage are in any way the recipients of electrical currents. It is fair to add, however, that it has been stated, on fairly good evidence, that watches are sometimes hopelessly upset after a journey of this kind. By hopeless, we mean to say that it is beyond the skill of the ordinary watchmaker to put the watch in proper repair. In such circumstances the owner should go to an electrician, who will demagnetise the watch. Supposing an occurrence of this sort to take place, it certainly proves *primâ facie* the existence of magnetic currents inside the electrical carriage. Assuming, for present purposes, the presence of electricity, the next step would be to find out the effect of that mode of travelling upon rheumatic passengers. A marked decrease of the ailment amongst habitual travellers might be expected if the cars in question were in any sense curative of rheumatism, but thus far one has not heard of any marked decline in the incidence of the disease. Then there is the fact that professional electricians, a most indefatigable and ingenious class of specialists, do not claim to be able to cure rheumatism by means of the application of electricity. On the whole, then, it seems probable that alleged cures of this widespread malady by travelling on electrical railways are purely imaginary. In one case investigated by the present writer an individual was said to have been cured by placing himself, under the advice of a guard, in certain positions in an electrical railway carriage. Further inquiry, however, showed that there was no real cure, but only a temporary remission of the pains of a subacute and recurrent muscular rheumatism. The same patient might just have readily imagined himself cured by hypnotism, by wearing an anti-rheumatic rug, by the virtues of some special underclothing, or by any other of the manifold forms of faith-curing for rheumatic ailments which are being constantly foisted upon a credulous British public. It is somewhat curious that a disease, the treatment of which is now well within the grasp of medical science, should still afford a happy hunting ground for quacks and charlatans. One of the greatest therapeutic triumphs of the present century has been the introduction of salicylic acid and the salicylates as specifics in rheumatism. The introduction of those drugs has robbed a dire disease, and one to which inhabitants in our variable climate are especially prone of half its terrors. For all that, we are bound to admit that the gratifying results of modern treatment are in this instance empirical, and that the etiology of rheumatism is still obscure. It is to this obscurity, indeed, that we must look for the only possible explanation of the marvellous hold that some notorious quacks have contrived to gain upon the public with their anti-rheumatic remedies. One does not altogether wonder that the imagination of folks generally should be captivated by the mystic pleasantness of the idea of curing their aches and pains by the simple prescription of a railway journey. Instead of swallowing nauseous physic the patient would merely look out an amusing book, take his ticket, and stepping into a well-lighted and well-cushioned carriage, be whisked away for an eighty or a hundred mile ride. It cannot be denied that to most people, chasing health after this fashion would be infinitely preferable to going "the round of the consultants." In the face of such an alluring picture it is with regret that we find ourselves compelled to state definitely and concisely that no scientific foundation exists to warrant this modern romance of elegant therapeutics.

◆

TUBERCULOSIS IN CATTLE.

The investigations of recent years, tending as they do to widen the horizon of pathological investigation in respect of the diseases of animals, have made the subject of tuberculosis one of universal interest, not only to the anxious mother who sees her offspring threatened by this national plague, but to the butcher, who is being made to understand that tuberculous meat is unfit for consumption as human food, and to the cattle breeder, who sees his profits become subject to deductions on account of animals sacrified on the altar of hygiene. The great publicity which has been given of late years to the diseases of animals capable of transmission to man has brought into forcible relief the lamentable ignorance of veterinary authorities on many of the most important points under discussion. At present it looks as if, before many years, the fillip given to researches in animal pathology would raise veterinary science from its present subservient position to a department of medicine as a whole. The more we realise the intimate connection between the diseases of animals and those of man the more we shall see that the care of sick animals cannot safely be left to comparatively uneducated practitioners whose low standard of scientific attainments is thought good enough for animals. It is not only in respect of tuberculosis that public curiosity has been aroused. Scarlet fever, diphtheria, and cow-pox all call urgently for highly skilled study in respect of their communication from animals to man and *vice versâ*. The prevalence of tuberculosis among animals in Canada and the United States has led to the imposition of certain tolerably stringent restrictions in respect of the importation of live cattle, and in order to assist in getting the more onerous of these restrictions removed or modified, some interesting observations have recently been carried out at Ottawa, in Canada, for the purpose of determining how far tuberculin administered in injections can be relied upon to afford accurate information as to the presence in any given animal of tubercular lesions. These investigations extended over a year. The tuberculin employed was most carefully prepared, and in each case it was injected just under the skin behind the shoulder-blade. If, after injection, the temperature rises considerably this is regarded as demonstrating the existence of tuberculosis; if, on the other hand, there is no rise of temperature the animal is regarded as free from the disease. The value of these investigations depends, of course, on the degree in which the temperature indications during life are confirmed by the results of post-mortem examination. It is officially stated that in all cases in which the characteristic rise of temperature took place, the animal, when slaughtered, proved to be suffering from tuberculosis, the seat of the disease being usually the lungs. Since November, 1892, some fifty-four animals have been thus tested on one farm, and of this number, twenty-six gave the reaction to tuberculin. The report says:—"The trustworthiness of tuberculin as a ready method of diagnosing this disease has been further confirmed, and it is believed that by the general use of this fluid the means will be found of detecting all cases thereof, and if detection be followed by prompt isolation, disinfection and disposal of affected animals, there would assuredly result after a time a greater immunity from this dangerous malady." The New York State Legislature has provided for the appointment of three inspectors, whose duty it is examine the herds in each county, and have affected cattle killed. A physical examination is first made, and if the existence of tuberculosis is suspected, tuberculin is injected, when, if the temperature reaction takes place, the animal is killed. A post-mortem is then made, and a report thereof is transmitted to the State Board of Health. Some 20,000 animals were examined by the three inspectors in 1893, and of this number, 686 were found to be infected and were killed. Only experiments on apparently healthy herds, however, will show whether the negative information afforded by injections of tuberculin is as valuable as the positive indications. An important observation has been made in respect of the effects of second injections. It has been found, in fact, that tuberculin rarely causes as strong a reaction after a second injection, even when several months have been allowed to intervene. Moreover, when a second injection is made shortly after the first, the reaction is usually slight or absent, although the animal may be badly diseased. This obviously vitiates to some extent the value of the test, because if it be conceded that only the results of the first injection are to be regarded as trustworthy, it will not be long before wily breeders will take advantage of this saving clause to protect their suspected cattle against summary slaughter.

◆

The annual *conversazione* of the Royal Society will be held this evening (Wednesday).

Notes on Current Topics.

Dispensing Extraordinary.

An account is given in the last number of the *Chemist and Druggist* of an inquest at Sheffield on the body of a child aged four months, who succumbed to the effects of the ingestion of Dover's powder. It seems that the father, on the advice of "a young medical friend," purchased a powder from a local chemist, omitting to state that it was not for himself. The chemist thereupon gave him *fifteen grains* of Dover's powder, equivalent to one and a half grains of opium, a full dose even for an adult. Half of this was given to the unfortunate infant with a fatal result. No directions, not even a label, were placed on the powder by the chemist, yet the coroner's jury found in their verdict that death was due to "inadvertence." This is only another example of the indifference of the law in respect of accidental deaths. An accident it assuredly was, but it was an accident caused by the grossest negligence, especially on the part of the chemist, who deserved exemplary punishment for his share in the catastrophe.

The Sale of Carbolic Acid.

It is to be hoped that the Pharmaceutical Society will not rest content with the unsatisfactory reply given by Mr. Acland when asked to include carbolic acid among the scheduled poisons. This official evidently regarded the request as a dodge of chemists to obtain the monopoly of the sale of this much-used disinfectant; but it was surely unnecessary to invoke any such unworthy motives in view of the terrible and increasing number of deaths from accident and suicide attributable to the indiscriminate sale of so poisonous a drug. With extraordinary rapidity carbolic acid has climbed to the second place in the list of poisons employed by suicides and in occasioning deaths by accident. What more is wanted to prove the immediate necessity for restricting the sale? It would possibly be too sanguine to hope that we are within measurable distance of a recasting of the laws regulating the sale of poisons generally, in spite of the numerous and gross abuses to which it is, from time to time, our painful duty to call attention.

Death in a Police-Cell.

Another of those sad cases in which a dying man has been locked up in a police-cell on a charge of drunkenness occurred last week at the Portland Town Police-station, St. John's Wood. The matter was reported to the magistrate at Marylebone by a police-sergeant, whose evidence was to the following effect: About half-past five o'clock in the afternoon of the 24th ult., a gasfitter, aged 58, was found lying in the street by a police-constable, who took the man into custody as drunk and incapable. The charge against deceased was entered at the police-station at a quarter to six, and he was then placed in a cell. About twenty-minutes to nine the same night, it was discovered that the man was ill, and a doctor was sent for, but before his arrival the accused had expired. The magistrate, so we gather from the newspapers, recorded this report in his book, but the public interests demand further inquiry into the affair. Had the constable who first found the dying man had any training to enable him to distinguish between drunkenness and apoplexy? Had the sergeant or inspector who took the charge any such special knowledge, and if not, why not? The power to distinguish between the two cases can be learned in the course of an evening by any person of average intelligence. There can be no shadow of an excuse, therefore, for the want of such information on the part of the police, to whom the safety of unconscious people in the streets is entrusted. In the case quoted, the very age of the patient is suggestive of cerebral mischief. One would have thought that any official whose experience warranted his being placed in so responsible a post as the charge of a police-station would at least have mastered the elementary tests to distinguish between the condition of drunk or dying. The scandal of sick persons being thus thrust into a police-cell to die has been before the public for many years. It is a question in the settlement of which every citizen is directly concerned. At least, it might be made an absolute rule that in any case presenting the slightest doubt, a medical man should be called in at once. It is high time the authorities were compelled to take steps to dispose of this standing menace to the public safety.

Lantern Slides as an Aid to Clinical Teaching.

The demonstration of microscopical sections of morbid growths and other objects of medical interest by means of lantern slides has been found exceedingly useful, and according to Dr. Kelly, who contributes a short paper on the subject in the March number of the *John Hopkins Hospital Bulletin*, this plan of instruction is capable of extension in the direction of being used as an aid to clinical teaching. In plastic and abdominal operations, for example, he remarks that comparatively few spectators can approach sufficiently close to enable them to follow the minor details upon which the success of the operation so often depends, but by this method all can have an equal view, and special points in technique which it would be impossible to demonstrate in any other way can be made clear. Lantern pictures, moreover, have also been found to be of the greatest value in showing the variations in contour of the abdomen in myoma, ascites, ovarian cyst, &c., as successive slides which bring out the differential points in diagnosis are able to be thrown upon the screen, and the student can thus obtain a much more definite idea of the subject than would be possible from a didactic lecture or demonstration upon a patient. Dr. Kelly at a recent demonstration showed the following slides:—Papillary cyst; specimen of pyosalpinx; extra-uterine pregnancy; elephantiasis of the labia; contour views of the abdomen distended by myoma uteri; ascites, and ovarian cyst; cystoscopic instruments; postures in cystoscopic examination; catheterisation of ureters by the direct; method clitoridectomy for carcinoma showing steps of operation from beginning to completion (5 slides); vaginal hysterectomy (15 slides); various forms of prolapsus uteri, and steps in the operation for its radical cure (11 slides); ovarian cyst removed by abdominal incision, showing method of tying the pedicle, position of surgeon and assistants around the operating table during the laparatomy. There is no doubt that this method would prove of the highest use in post-graduate courses, and a surgeon with a good set of slides would always be certain to attract a large audience.

The Psychology of the Weather.

A new, and what must prove to be an interesting field for investigation has just been suggested, namely, that of the psychology of the weather. A few observers have already paid some attention to it, and so far the results of their inquiries would appear to point to the fact that many very powerful forces, coming from what is popularly called the weather, control the work and success of brain workers. Experimenters, and others engaged in mental tasks of an exacting description, have found faulty deductions and misconceptions as the result of their work in damp, foggy weather, or on days in which the air was charged with electricity and thunder clouds were impending. Indeed, deductions which seemed clear at these times appeared later to be filled with error. It is also stated that an actuary in a large insurance company is obliged to stop work at such times, finding that he makes so many mistakes, a fact of which he is only conscious when he subsequently ascertains that his work is useless. A further confirmatory fact is that in large factories from ten to twenty per cent. less work is brought out on damp days and days of threatening storm than on days when the weather is fine. It is quite easy to understand the psychological effects of bad weather. Doubtless some of the phenomena arising therefrom are due to a higher state of impurity of the atmosphere than that which is present under the influence of the fulness of the sun's rays. Common observation teaches that in dull, damp, foggy weather there is less inclination to indulge in physical exercise, less inducement to undertake anything which involves much physical exertion. On the other hand, bright sunny weather acts as a stimulant to human energy, when not excessively hot, and probably at these times there is more oxygen in the atmosphere and less carbonic acid.

Depopulation and Alcohol.

Some statistics have been collected which point somewhat in the direction of showing that depopulation and alcoholism are more or less associated. In France careful investigation has revealed that the decline in the birth-rate, at least in certain districts, has coincidently occurred with a pronounced increase in the consumption of alcohol. In 1885 the returns indicated on an average the consumption of 100,000 hectolitres of alcohol per annum. On the other hand, in 1892, the consumption was 375,369. According to the most recent statistics every individual in France, in 1892, drank 4·56 litres of alcoholic beverages, while for other countries the amounts have been computed as follows:—In England, the consumption was 2·70 litres; the United States, 2·82 litres; Russia, 3·07 litres; Holland, 4·49 litres; Belgium, 4·91 litres; Germany, 4·40 litres. Thus the greatest consumption of alcoholic liquors appears to take place in Belgium, while France is a good second for the same unenviable distinction. Some further points, however, in connection with this subject are by no means uninteresting. Statistics show that in the midland districts of France there is scarcely any alcohol drunk, while in Paris as much as 7 or 8 litres per head are consumed. But even this large figure is exceeded in other districts, so much so that in one the consumption per head reaches no less than 13 litres. The French population has been declining for the past twenty years while the alcoholic proclivities of the people have been increasing.

Insanitary Government Offices.

In a letter to a morning contemporary a correspondent calls attention to the over-crowded state of a room known officially as the "Cable Room" in the General Post Office. The exact figures showing the air space per man in the room in question work out on an average of 279 cubic feet. The writer remarks: "Government Departments are supposed to be free from all legal restraint, but surely it is nothing short of hypocrisy for the Secretary of State to lay down a law on behalf of the Government, and to rigidly enforce its restrictions upon private employers, while another member of the Cabinet is allowed to conduct the department immediately under his control with a total disregard of the wishes of the Cabinet of which they are both members. The badly ventilated and over-crowded condition of many of the departments at St. Martin's-le-Grand is notorious. The explanation of this unfortunate state of affairs probably lies in the fact that the present building is the outcome of many piecemeal additions or alterations. There has, consequently, been no definite application of a properly-constructed scheme of ventilation, and a similar statement applies both to drainage and to structural points generally." The old-fashioned gas burner still holds its place in the General Post Office, and adds considerably to the air pollution. A report on the sanitary state of this important building would, if we mistake not, afford some interesting reading.

Is Permanganate of Potassium an Antidote to Morphia?

Some interesting experiments upon dogs in which the efficacy of permanganate of potassium as an antidote to morphia was tested, have just been recorded by Dr. Rector, of Jersey, New York. The experiments consisted of two series, one in which morphia was administered, and the remedy applied, the other in which the morphia was given alone. In neither case did a fatal result occur. In the first series two dogs were taken, and into each five grains and six grains of sulphate of morphia were injected respectively. The usual physiological effects of the drug were produced, and recovery followed after the administration by the mouth, in the first instance of five grains and in the second eight grains of the permanganate of potassium. Then the author ascertained that authorities had asserted that from eight to ten grains of morphia was the quantity required to kill an ordinary sized dog. Accordingly into another dog he injected twelve grains of the alkaloid. No antidote was given; the animal was left entirely to itself, but despite this, in thirty-six hours it had quite recovered. The experiment was repeated in another case with a dose of fifteen grains of morphia, but the dog's recovery, without the antidote, was nevertheless complete. Clearly, therefore, these investigations leave the claims for the antidotal properties of permanganate of potassium to morphia in an unsatisfactory state. Apparently further inquiry is requisite before the facts can be definitely established one way or the other. As the subject is one of much interest and importance it may be hoped that some well-known physiologist will take it up.

How Typhoid is Spread.

An application made to the magistrates a week or two since by the Assistant Medical Officer of St. Helen's throws a vivid light on the manner in which disease is fostered and spread amongst the poor of our great cities. The evidence showed that a patient died from typhoid fever, that there were two rooms, and that the body was lying on the ground floor, where the inmates lived and where all the cooking went on. Under these circumstances there was danger of the infection spreading, and the sanitary authorities accordingly asked for an order authorising the removal of the dead body to the mortuary. The magistrate granted the application on the understanding that the relatives should be allowed to bury the body if they wished to do so. This incident, with all its ghastly realism, brings into startling prominence the conditions under which the dead are retained in the dwellings of the poor. Under any circumstances the presence for days together of a corpse in the living rooms must be undesirable, but when to this is added the contagion of specific disease the position constitutes so great a danger to the living that it becomes necessary for the law to intervene. The obvious remedy would be the immediate removal of the dead in every instance to public mortuaries, but public opinion is by no means sufficiently ripe to permit such an innovation. In matters of this kind, where sentiment is involved, it is specially advisable for those interested in sanitary progress to proceed with the greatest caution.

A Centenarian Patient suffering from Gonorrhœa.

The precise period at which the sexual functions in man cease to become assertive is a point which has still to be definitely determined, but the current issue of the *New York Medical Record* publishes the notes of a case by Dr. Isaacs the remarkable feature of which is that the patient was a man of one hundred and three who came under treatment for an acute attack of gonorrhœa. He was a native of Ireland, and he married when he was fifty. Previous to his marriage he had never had sexual connection. His eldest living son is now fifty years of age, and his youngest thirty-three. His second wife died twelve years ago, and since this domestic affliction he appears to have considerably "fallen away" from the paths of virtue, having, so far, now suffered from four attacks of venereal trouble. Three years ago it was soft chancres which he contracted; at present it is gonorrhœa, and he was infected with the latter through a widow woman to whose support in a perfectly friendly manner he contributed. This method of requital for having helped her and her children he naturally bitterly laments, and his lamentation is not surprising. The surgeon reports that his genitals are well developed, and show no signs of senility. Under the circumstances, therefore, it is clear that this vigorous old patient should take measures to avoid in the future contingencies of a venereal description by entering for the third time the state of wedlock.

Typhoid Fever in Indian Military Service.

Under the *nom de plume* of "A Military Doctor" a correspondent has lately written to a weekly paper drawing attention to the mortality from enteric fever amongst our soldiers in India. He states that every year about 400 men die from that disease out of a total of 1,300 cases. If his figures be correct this points to a very serious state of affairs and one that demands searching inquiry. He may well call this a "horrible death rate," and if his statement that the nursing is left to chance soldiers and native attendants, "the lowest of the low, the scum of the bazaars," be borne out by facts he has indeed framed a heavy indictment of the present system. "What is wanted," he says, "is that some 500 or 600 non-commissioned officers and men of the Medical Staff Corps should be sent out to India to work in the army hospitals there, and they should be in addition to the other British troops in the country." While agreeing with the writer that the sick of a large army should be looked after by a properly trained and organised nursing corps, we cannot help thinking that the writer has not quite got at the root of the matter. Enteric fever is the result of a specifically poisoned water supply or of other grossly defective sanitary environments. It would be sounder, surely, to aim at prevention of the disease by attention to hygienic matters than to trust to good nursing to avert the after consequences.

A Burglar's Therapeutics.

A boy burglar of sixteen was committed for trial at Bradford last week on several charges of housebreaking and felony. It was stated that in searching the lad's room a document headed "Instructions to Burglars" was found between the joists of the floor. In this modern guide to Tyburn some extraordinary passages occur with regard to the criminal use of drugs, from which we quote the following:—"Get some chlorodyne from the chemists, and put it on your handkerchief and put it over some one's noses, which will send them unconscious. Then take all the expensive things he has. If you have a desire for revenge on any one, you can get some prussic acid, and when you are handing him or her drink put the acid in, or get some vitriol and throw it on someone's faces in the dark, which will burn their face. If you put poison on a knife when the knife is red-hot, the knife will be poisoned." We fancy that the enterprising burglar who tried to make his victim unconscious by the inhalation of chlorodyne would find his patience severely taxed. Upon reading the foregoing extract one reflects somewhat uncomfortably that there would be little difficulty in the way of the would-be criminal obtaining his drugs from the chemist, so defective is our poison law.

Anti-Vaccinationism in Dublin.

Those who value the public health of Dublin will note with regret and alarm that the Guardians of the South Dublin Union decided last week, by a majority, to abstain from enforcing the Vaccination law against one of those enthusiastic but stupid and ignorant persons who think that their conscience justifies them in disseminating small-pox. The decision of the Guardians does not appear to have been premeditated, and we are therefore led to hope that when the Board has time to think the matter over, it will see that it has made a huge mistake, and will be ready to go back from its hasty judgment. We decline to discuss the question of the efficacy of vaccination, and the Guardians may, with advantage, abstain from doing so considering that they could, at best, know next to nothing about the subject, and their decision would be entitled to scarcely as much respect as that of the Royal Commission which has the subject now under consideration. But, at least, the Guardians ought to realise that their sentimental refusal to prosecute in any one case is equivalent to a total abrogation of Vaccination law within their district. Do they for a moment suppose that the Dublin poor would be impelled by any belief in the efficacy of vaccination, or, indeed, by any care whether it is efficacious or not, to bring their children to be vaccinated? Do they not know perfectly well that, as soon as it becomes known that it can be done with impunity, three out of every four poor mothers will throw the doctor's vaccination requisition behind the fire and leave their children to grow up unprotected against small-pox? Should this occur, it is obvious that it will be useless for the dispensary medical officers to issue such requisitions or to make returns of defaulters to the Guardians, and the whole system would collapse. The South Dublin Guardians may think that it is well that it should collapse, but we submit that they have no right to form any judgment on that point, for it is their duty to carry out the law confided to them, and to leave it to higher authorities to repeal that law. In any case it is not their duty to subject to any risk the lives and health of the ratepayers who provide the money, and who have elected them, and it is outrageous that they should do this at the bidding of half a-dozen crazy fanatics who have not learned, refuse to learn, and, possibly, are incapable of learning anything about vaccination.

The Modern Army Medical Officer.

Surgeon Major-General Collis, in the course of a speech at a farewell dinner held in Dublin on his retirement, made some pertinent remarks on the present conditions of the service. For instance, he pointed out that the medical officer of to-day is expected to be a first-class professional man, ready to deal with any case in the whole range of surgery or medicine that might be placed before him. This constituted a kind of universal specialism which had been demanded by the conditions of foreign service. For a man to keep abreast of the rapid advances in professional knowledge it was necessary for him to obtain leave for special study. That meant an increase of numbers, which was the policy he would impress on the Army Medical Staff. An army medical officer, besides being well versed in his profession, must be a sanitarian. His duties, moreover, include those of paymaster, quartermaster, a knowledge of military law, of company drill, and of the special drill and instruction required by bearer organisation. The speaker expressed his belief that no corps can point to a higher percentage of killed and wounded than the Army Medical Staff. Surgeon Major-General Collis, whose reason for retirement was the attainment of the age of 60 years, held the post of Principal Army Medical Officer in Ireland.

A New Medical Grade.

Sir B. Ward Richardson, in the last number of the *Asclepiad*, advocates the recognition, examination, and registration of counter-prescribers. He says, first, that they are honest practitioners in their way; second, they are useful to the public under certain circumstances; third, whether they are or not, they are certain to continue to exist, because it would be almost impossible to put in action any law for their suppression, if it were desirable to do so. But he would not tolerate the counter-prescribers' invasion of visiting practice under any circumstances. *Et tu Brute!* If our memory serves us, we attended not many years ago a meeting of general practitioners convened in London for the defence of the general practitioner against counter-prescribers and all such, and at that meeting Dr. B. W. Richardson—not then Sir—"spoke like thunder on our side, bidding us depend upon his valour, his arms, and his strength," and has "he now fallen over to our foes"?

The appeal by the proprietors of Powell's Balsam of Aniseed against a conviction by the County Court Judge of Derby in a case brought by the Pharmaceutical Society, was dismissed last week with costs by Mr. Justice Charles and Mr. Justice Bruce.

A protest against the proposed Fever Hospital at Chingford has been signed almost without exception by the Members of Parliament for London.

Herpes Labialis as a Diagnostic Sign.

An inquiry into the bacteriology of herpes labialis has revealed some interesting points. The fluid contained in the vesicles teams with micro-organisms, and the conclusion deduced from the nature and variety of the latter is that they are the cause of the eruption as well as of the primary disease with which the vesicles are associated. In nineteen cases of herpes examined, in fourteen the contents of the vesicles were found to contain pneumococci, staphylococci, and streptococci, but in every instance only in one form. In five of the cases in which the contents had already become turbid, streptococci and staphylococci were present. It is pointed out that herpes occurs commonly in the course of diseases (such as pneumonia) caused by micrococci, or (such as rheumatism and endocarditis) in which micrococci cause secondary infection, and with but extreme rarity in the course of diseases (such as typhoid, diphtheria, and tuberculosis) that are dependent upon specific micro-organisms. These facts are of value clinically, and might in some cases be helpful in clearing up a difficulty in diagnosis.

Notification of Measles.

We observe that the Medical Officer of Health for Jarrow-on-Tyne, one of the first and most ardent advocates of compulsory notification, has been obliged to confess that, at least as regards measles, the system has proved a rank failure. He admits that it has resulted in an enormous increase in the number of cases notified, and a still more enormous increase in the death-rate from that disease. In the two years preceding 1891, 631 cases and 29 deaths from measles were gazetted; in the two years succeeding 1891 the cases were 2,079 and the deaths 123, an increase of nearly fourfold. The Medical Officer of Health, of course, tries to find an explanation for this monstrous increase in a variety of causes, hidden away amongst which we find the true reason, "want of universal notification." That concealment of the disease has developed under the influence of the compulsion system is indicated by the fact that in 1892 the mortality was at the rate of 4 per cent. of the cases notified, while in 1893 the mortality had advanced to 8·2 per cent.

Rachitis as a Cause of Hernia in Children.

Dr. Southgate, in a contribution to the current number of an American contemporary, discusses the relation between rachitis and hernia in children, and from the study of seventy-one cases of rupture, he found 29 5 per cent. were in children who were suffering from rickets. He concludes that there are grounds for the belief that the latter disease may act as a predisposing and exciting cause of ruptures in children, mainly by increasing intra-abdominal pressure and abdominal distension, consequent upon the enlargement of the abdominal viscera, also by a depression of the abdominal contents by a contracted thorax, and a mechanical distension of the belly walls.

The Richmond Hospital, Dublin.

This celebrated old hospital has for years worked under the difficulty that its structural arrangements are far from being up to date. It was not originally built for the purpose, and if it had been, times have changed and have rendered reconstruction necessary. For years past, therefore, the Governors have had their attention fixed upon a project of reconstruction, and have only waited for Government assistance or public help to enable them to enter on the work. We learn with much satisfaction that they have recently received a generous contribution to the necessary fund in the form of a gift of £5,000 from Mrs. Hamilton, of Merrion Square, widow of the late Mr. John Hamilton, some time surgeon of the hospital. The sum has been placed in the hands of Trustees, and the Board of Governors has passed a resolution of warm thanks to Mrs. Hamilton for her beneficence.

A Useful Suggestion.

The suggestion has been made that pneumatic tyres should be provided for ambulance wagons and similar vehicles in which sick or injured persons are conveyed from place to place. This would be a distinct improvement were it carried out. The jolting and shaking which takes place under the present system would by this means be almost entirely banished, and patients would have but little reason to dread being transferred in the conveyances in question. We trust that the suggestion will be acted upon. The Metropolitan Asylums Board might lead the way by having pneumatic tyres attached to their ambulances.

The Late and Future International Medical Congresses.

A letter from Signor Guido Baccelli to Señor San Martin, the delegate of the Spanish Government to the International Medical Congress at Rome appears in *El Siglo Médico* acquainting him of the generally expressed wish that the meeting subsequent to the St. Petersburg Congress should be held in Madrid. The proposal is favourably entertained by Señor San Martin, who warmly recommends it in a letter to the Marquis de Guadalerzas, proprietor and principal editor of our contemporary.

Sympathy with Dr. Griffiths.

The Swansea Medical Society, at its meeting on the 19th ult., unanimously passed the following resolution: "That this meeting desires to express its sincere sympathy with Dr. T. G. Griffiths in having to defend himself against the gross and slanderous charges brought against him in the recent divorce case. The Society further desires to convey to him its hearty congratulations on the successful issue of the trial, and the ample exoneration he received at the hands of the jury, with the concurrence of the Lord Chief Justice in their verdict."

Dr. Laurence Humphry, of Trinity College, Cambridge, has been appointed an additional Examiner in Medicine and Surgery for the present term.

Cholera at Lisbon.

The latest information is to the effect that despite assertions to the contrary an outbreak of cholera is coming nearer home and has reached Lisbon. It is, however, satisfactory to note that the Medical Officer sent by the Spanish Government to investigate the outbreak has reported that the disease is of a benignant type. A few deaths have occurred, but a great number of persons have been attacked, for the most part adults. In the majority of cases the progress of the attack is rapid, and the patients begin to recover on the third day, but relapses are frequent and serious. Telegraphic despatches have reported that the Portuguese Medical Society have held a meeting at which 80 members were present, and have passed a resolution declaring that the present epidemic was one of Asiatic cholera, and that although of mild form the disease still constituted a serious peril. It was also decided to advise the Portuguese and Spanish Governments to take the necessary precautions against its dissemination. The supposition is that the epidemic probably owes its origin to imported cases from the Cape de Verde Islands, where the disease raged last year. Meanwhile, in consequence of this outbreak, the Medical Officer of Health for the Port of London has notified all shipowners and brokers that vessels trading from or calling at Lisbon, will, from the 28th ult., be subjected to medical inspection on arrival at Gravesend.

Professor Redfern, the distinguished veteran anatomist of the Queen's College, Belfast, has been presented with two portraits of himself from the brush of Mr. Ernest Taylor, one of them for the Hall of the Queen's College, and the other for the Professor's family. The presentation took place on the 13th of April, and the chair was occupied by the President of the College. The various speakers, including Professor Purser, Mr. Sinclair, D.L., and the President of the College, expressed to Professor Redfern their grateful sense of the long and valuable services rendered to the College and to education.

Dr. William Russell, of Edinburgh, known for his work on the Heart, and on the Parasitic Origin of Cancer, and at present the holder of the Cullen Prize of the Royal College of Physicians, Edinburgh, has consented to deliver the Summer Course of Lectures in Pathology, in place of Dr. Barrett, who has had to resign his post through ill-health.

A medical man in St. Petersburg, Dr. Thomas Piotrovitch, has been condemned to seven days' imprisonment and to pay a sum of 1,000 roubles as damages, and further to make an annual allowance of 300 roubles, to a lady who brought against him an action for malpraxis.

Sir Thos. D. Gibson-Carmichael, Bart., has been appointed by H.M. the Queen on the recommendation of the Secretary of State for Scotland, to be Chairman of the Lunacy Board for Scotland.

Dr. J. H. Galton, of Upper Norwood, was fined at the Bromley Court on Monday last, forty shillings and costs for failing to notify a case of typhoid fever under his care.

Surgeon-Maj.-Gen. T. Pinkerton, retired list, has been appointed Honorary Physician to the Queen. He served in the Persian campaign, 1856-7.

Dr. Wallace, Member for East Edinburgh, is a candidate for the vacant Coronership for East London.

MEDICAL SOCIETY OF LONDON.

Last Monday evening's meeting was devoted mainly to two papers on intestinal surgery. One was a case related by Mr. Battle in which a man who had been kicked by a horse was brought to St. Thomas's Hospital with symptoms pointing to rupture of intestine together with laceration of the mesentery or omentum. As soon as he had rallied from the shock of the injury the abdomen was opened, when it was discovered that besides laceration of mesentery there were three ruptures of small intestine, two of them being complete. These he joined end to end, after resection, repairing the third without resection. The man did splendidly for a time, but ultimately he succumbed to peritonitis resulting from the giving way of the sutures, their giving way being due probably to the sutures having been placed in bruised tissue and partly to the damage to the mesentery interfering with the blood supply to the corresponding parts of the intestine.

Mr. Herbert Allingham mentioned a somewhat similar case in which laceration of the mesentery was followed by gangrene of the corresponding portion of bowel.

The other case was one by Mr. Herbert Allingham. In this case the patient came in complaining of intestinal obstruction, for the relief of which an opening was made into the cæcum. The man did well, but the discharge from the wound annoyed him so much that he returned requesting that something might be done. The abdomen was opened, and a tight fibrous stricture was found in the descending colon. This was excised, and the ends joined by means of a Mayo Robson bobine. The man did well, and the opening into the cæcum was closed. He returned to his home in Southampton, and subsequently rode up to the hospital in London on his bicycle. A month or two later, however, symptoms of obstruction returned, and another operation soon became necessary. On opening the abdomen, however, the peritoneum was found to be studded with nodular masses, and other masses were felt in the small intestines and mesentery, so, as nothing could be done, the wound was simply closed. He died two months later, when the resected part was found in a perfect condition, death being due to the spread of the secondary deposits.

Mr. Harrison Cripps urged that the incision in cases of chronic intestinal obstruction should be made in the left side in order that, if necessary, it might be converted into a colotomy. Failing relief by this means, the wound was to be closed and an opening made into the cæcum. This usually relieved the symptoms and left the operator free to choose his own time for the steps having for object the permanent relief of the obstruction.

The last meeting takes place *next* Monday.

Obituary.

DR. GIBSON, OF NEWCASTLE.

By the death of this gentleman a few days since, Newcastle-on-Tyne loses from its midst a citizen whom it delighted to honour, and the profession of medicine a courtly, and highly-educated physician. The immediate cause of death was an apoplectic seizure, but three weeks ago he had an attack of pneumonia, which completely prostrated him. From this, however, he was making a fair recovery, and no immediate danger was apprehended, but the sequel was sudden, and he passed away unconsciously at the age of 74. He was one of the earliest students educated at the Durham School of Medicine, and in the Winter Session of 1845-46 he was appointed Lecturer in Anatomical Demonstrations and Dissections at the same school. On the formation of the new College of Medicine, Dr. Gibson became Lecturer on Midwifery and Diseases of Women and Children, and a member of the Council. In 1856 he was elected physician to the Newcastle Dispensary, and on resigning that post in 1873, he was elected consulting physician. In 1859, the degree of M.D. was conferred upon Dr. Gibson by the University of Durham in recognition of his services to the College of Medicine. After having been some years physician-accoucheur to the obstetrical charities of Newcastle, Dr. Gibson pointed out the necessity for an hospital where the diseases of poor women might meet with proper treatment, and he took a leading part in establishing the present charity, which was opened in 1866. Deceased was also an Examiner in the University of Durham, and his connection therewith extended over half a century.

◆

DR. DOUGLAS, OF WARRENPOINT.

This most estimable and respected member of our profession died last week from pneumonia at his residence at Warrenpoint, after an illness of fourteen days, at the comparatively early age of 59. Dr. Douglas was one of the best of our fraternity in the North of Ireland. He was well educated and capable as a practitioner; but in addition, was straight, honest, and kindly, and never spared himself when, by self-sacrifice, he could serve a good cause. Dr. Douglas was the son of Capt. Ed. Douglas, R.N., and was educated at the Irish College of Surgeons and Peter Street Schools, and, after studentship, served for a little time as a demonstrator at Steevens' Hospital, until he settled in Newry. He took the Fellowship of the Irish College of Surgeons in 1874.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

MEDICAL ETIQUETTE IN THE ISLE OF THANET.

In a recent impression we drew attention to the fact that a certain baker at Ramsgate had printed on his paper bags, a testimonial signed by Dr. Chaning-Pearce, side by side of other articles of his trade. No member who values the honour of his profession could possibly approve of such methods of advertising, and it affords us pleasure, therefore, to publish the following explanation, which Dr. Chaning-Pearce has also caused to be inserted in the correspondence columns of the local newspapers :—

Sir,—My attention has just been called to the publication, by a local tradesman, of an opinion I wrote him some time ago, about an article of his manufacture. This opinion I gave with no intention whatever of its being so advertised: on finding that it was so, I have at once taken steps for its withdrawal, and shall be obliged if you will allow me thus to call attention to the fact.

Yours truly,
J. Chaning-Pearce.

Montague House, East Cliff, Ramsgate,
April, 1894.

Some months ago Dr. Chaning-Pearce kindly, at our request, gave us a testimonial about Triticumina bread, which we displayed in our shop window, but at his request withdrew. We now are sorry to find that we have, unknowingly, caused him annoyance, by having his testimonial printed on our bags, we have, therefore, agreed to at once withdraw this, and hereby certify that this display of the testimonial in the window and on the bags was without his knowledge or consent.

(Signed) B. F. Bryant,
For Bryant and Co.

◆

Literary Notes and Gossip.

An article entitled "Modern Surgery" appears in the current number of the *Nineteenth Century* from the pen of Mr. H. Percy Dunn, F.R.C.S.

⁂

Mr. Lewis announces for immediate issue in his "Practical" Series a volume on "Diseases of the Nose and Throat" by Dr. F. de Havilland Hall; and a new edition of Dr. Norman Kerr's exhaustive treatise "On Inebriety," will also be shortly issued by the same publisher.

⁂

A fifth edition of Mr. Field's well-known work on "Diseases of the Ear" is announced by Ballière, Tindall and Cox. We understand that the previous edition (a large one) was sold out in less than eight months—an almost unprecedented thing with a book on a "special subject." The same publishers announce a new edition of Dr. Ball's book on "Diseases of the Nose and Naso-Pharynx."

⁂

Dr. J. W. Ballantyne, of Edinburgh, has brought out the first number of *Teratologia*, or, "quarterly contributions to antenatal pathology." This is entirely a new step in medical literature. The contents of the number before us consist of a long and interesting paper on the fœtus amorphous, embellished with three plates. Then follows an article on "Fœtal Pathology in the Past," and the concluding papers are taken up with reviews, abstracts from current literature, &c. We wish the author success in his enterprise. Quite possibly there is an opening for a periodical of the kind.

⁂

The literature of influenza has been enriched by a huge quarto volume dealing with the epidemic of 1889-90. The author is Dr. Friedrich, a German, and it is at once evident that he has treated his subject with the marvellous minuteness and patient exhaustiveness of research which characterise the productions of his countrymen. Many interesting observations are recorded. For instance, it was found that in glass works those men who were employed at greatest distance from the furnace were attacked first. The disappointing thing about this monumental monograph is that no definite conclusion is arrived at with regard to the *fons et origo mali* of this mysterious malady.

⁂

Dr. Rentoul's staunchest opponent would hardly dare accuse him of self-interest or want of courage. Whatever that gentleman takes in hand is carried out with ceaseless energy, and obviously at great pecuniary outlay. His former onslaught on the proposed registration of midwives is stated to have cost him considerably more than £100, and now, at the moment of going to press, a pamphlet on the same subject from his pen and pocket reaches us, in which he discusses the whole question under the title of "The Proposed Formation of an Inferior Order of Midwifery Practitioners." We shall examine this pamphlet in due course, meanwhile, its publication is hereby placed on record.

⁂

The Manchester *Medical Chronicle*, with the April number, begins a new series. The familiar green cover has given place to one of a dark orange tint, and the size of the pages is slightly reduced. The professors and lecturers in the Medical Department of Owens College have taken it over, and will be responsible for its management in future. In an introductory notice it is stated that "every effort will be made to keep the quality of the journal up to as high a standard as possible, but no important alterations will be introduced into the arrangement and proportions of the contents, but the amount of matter will be at once considerably increased."

⁂

Among the new announcements of publications by Mr. David Nutt, no less than three are interesting from their connection with medical men. They are, "Lectures and Addresses (Biological and Zoological)" by the late Prof. Arthur Milnes Marshall, of Owens College, Manchester; "Welsh Folk-Vales, and other Stories," collected and edited by Dr. P. H. Emerson; and lastly, "A Philosophical Essay concerning the Pygmies of the Ancients," by Edward Tyson, M.D., (1699) edited, with notes and a preliminary dissertation on Pygmy races, ancient and modern, and their connection with tradition and myth, by Dr. B. C. A. Windle, Professor of Anatomy in Mason College, Birmingham.

⁂

NEW BOOKS AND NEW EDITIONS.—The following have been received for review since the publication of our last monthly list:—The Health Resorts of Europe, by Thos. Linn, M.D. Health at School, by Clement Dukes, M.D., B S. Lond. Treatise on Nervous Exhaustion, by Geo. M. Beard, A.M., M.D. Student's Handbook of Medicine and Therapeutics, by Alex. Wheeler, L.R.C.P.Ed. Dictionary of Active Principles of Plants, by Chas. E. Sohn, F.I.C., F.C.S. Annual Reports of the State Board of Health for Pennsylvania, vols. vii and viii. Lunatic Asylums, their Organisation and Management, by Chas. Mercier, M.B. Wright's Prescription Book. The Proposed Formation of an Inferior Order of Midwifery Practitioners, by R. R. Rentoul, M.D.

◆

Medical News.

Royal College of Physicians of London.

THE ballot for the election of Fellows of the Royal College of Physicians was taken at a meeting of the College on the 26th ult., when the following members were duly elected:—R. W. Burnet, M.D.Aberd., H. Davy, M.D.Lond., (Exeter), A. T. Davies, M.D.Cantab., M. Dalton, M.D.Lond., Lewis Jones, M.D.Cantab., J. S. Bury, M.D.Lond. (Manchester), W. L. Dickinson, M.D.Cantab., J. W. Washbourn, M.D.Lond., H. P. Hawkins, M.D.Oxon., H. D. Rolleston, M.D.Cantab., and E. C. Perry, M.D.Cantab.

West London Medico-Chirurgical Society.

THE Cavendish Lecture in connection with the above Society will be delivered by Sir William Broadbent, Bart., M.D., F.R.C.P., at the West London Hospital on Thursday, the 14th June, at 8.30 p.m., the subject being, "Some Points in the Treatment of Typhoid Fever." After the lecture the President and Council propose to entertain the members at a *conversazione*. The Council Dinner will be held at the Criterion Restaurant on Wednesday, May 30th, at 7 for 7.30 p.m. Members desirous of being present and of introducing guests are requested to intimate the Senior Secretary (Dr. Clemow, 1 Comeragh Road, West Kensington) as soon as possible in order that the necessary arrangements may be made.

The Sanitary Institute.

AT the Sanitary Institute Congress at Liverpool, Dr. Thomas Stevenson, F.R.C.P., Scientific Analyst to the Home Office, has consented to act as President of Section 3, Chemistry, Meteorology, and Geology. Dr. Edward Klein, F.R.S., has consented to act as President to Section 1, Sanitary Science and Preventive Medicine.

A Munificent Offer.

AT the opening of the bazaar in aid of the Manchester Southern Hospital in the new Medical School at Owens College on the 27th ult., Mr. Duncan Matheson announced that the trustees of the David Lewis bequest had made them the magnificent offer of £70,000 under certain conditions of amalgamation between the Southern and the St. Mary's Hospitals.

Royal College of Surgeons in Ireland.—Schools of Surgery.

PRIZE LIST, WINTER SESSION, 1893-94.

Descriptive Anatomy.

Junior.—Mr. J. Conway, 1st; Mr. F. J. Palmer, 2nd. Senior.—Mr. D. Kennedy, 1st.; Mr. W. M. Power, 2nd.

Practical Anatomy.

First year.—Mr. F. J. Palmer, 1st; Mr. J. Leventon, 2nd. Second year.—Mr. W. J. Sweeny, 1st; Mr. H. E. Eardley, 2nd. Third year.—Mr. M. Carroll, 1st; Mr. R. M. Hamilton and Mr. H. Montgomery equal, 2nd.

Practice of Medicine.

Miss C. L. Williams, 1st; Mr. A. C. Oldham, 2nd.

Surgery.

Mr. A. C. Oldham, 1st; Mr. G. E. J. A. Robinson, 2nd.

Midwifery.

Mr. P. J. Morrissey, 1st; Mr. A. Leventon, 2nd.

Physiology.

Mr. J. Thomson, 1st; Mr. F. Hefferman, 2nd.

Chemistry.

Mr. F. J. Palmer, 1st; Mr. R. H. D. Pope, 2nd.

Pathology.

Mr. A. Leventon, 1st.

Physics.

Mr. B. Scribner, 1st; Mr. G. F. Sheehan, 2nd.

Biology.

Mr. D. Hadden, 1st; Mr. B. Scribner, 2nd.

Conjoint Examinations in Ireland by the Royal College of Physicians and the Royal College of Surgeons in Ireland.

THE following candidates have passed:—

Second Professional Examination.

A. T. Benson, J. W. Benson, D. F. Clarke, H. F. Conynsham, A. A. Cooper, F. P. Cormack, K. Corsellis, H. E Eardley, E. A. Fenton, T. Fitzgerald, J. R. Hewetson, E. C. Hodgson, C. A. Kenny, M. R. L. Moore, B. McCaul, J. F. O'Keefe, F. J. W. T. O'Rorke, S. J. Scott.

The Royal University of Ireland.

Third Examination in Medicine.

Upper Pass Division.

Beggs, S. T., Queen's Col., Belfast, Rougham, J. A., B.A., Cath. Univ. Medical School.

The above candidates may present themselves for the further examination for Honours.

Pass Division.

Boyd, J. McA., B.A., Queen's Colls., Cork and Belfast, Burns, A., Queen's Col., Belfast, Carroll, W. S., Queen's Colls Galway and Cork, Cunningham, R. A., Queen's Col., Belfast, Davitt, R. E., Cath. Univ. Med. School, Floyd, S. F., Queen's Col., Belfast, Heron, F. T., Queen's Col., Belfast, McWilliam, W. A., Queen's Col, Belfast, Matson, J., Queen's Col., Belfast, Nixon, J. C., B.A., Queen's Col., Galway, Norcott, W. B, Queen's Col., Cork, O'Connor, D. J., M.A., Queen's Col., Cork, Smyth, W. S., Queen's Col., Belfast, Speller, W., M.A., Queen's Col., Belfast, Stitt, W. J., Queen's Col., Belfast, Trimble, A, Queen's Col., Belfast, Young, R. T., Queen's Col., Cork.

University of Durham.

THE following passed the second examination for the degree of Bachelor in Medicine at the April meetings of the Court:—

First-Class Honours.

Hatch, H. L., M.R.C.S., L.R.C.P., D.P.H, St. Mary's Hospital, London.

Coltman, James, College of Medicine, Newcastle.

Second-Class Honours.

Pearson, A. G. W., College of Medicine, Newcastle.
Senior, H. D., Charing Cross Hospital.
Dent, H. H. C., Mason College, Birmingham.
Rygate, A. M., Guy's Hospital.
Pratt, E. F., L.R.C P.Lond., Mason College, Birmingham.
Sutcliff, E. H., St. Thomas's Hospital.
King, J. W., College of Medicine, Newcastle.
Holgate, P., College of Medicine, Newcastle.

Pass List.

Anderson, J. C., Col. of Medicine, Newcastle.
Armstrong, P. L., Col. of Medicine, Newcastle.
Baker, Alexander, St. Thomas's Hospital.
Cahill, M. F., L.R.C.P., L.R.C.S., Catholic University, Dublin.
Carpenter, W. S., M.R.C.S., L.R.C.P., St. Mary's Hospital.
Dunn, R. A, M.R.C.S., L.R.C.P., St. Bartholomew's Hoopital.
Fell, W. G., Col. of Medicine, Newcastle.
Foster, J. J., Guy's Hospital.
Greaves, R. B., Sheffield School of Medicine.
Hughes, J. B, University Col., Liverpool.
Light, L. W., St. Thomas's Hospital.
Shapland, J. D., B.A., University Col., London.
Simmons, H., M.R.C.S., L.R.C.P., L.S.A., Bristol Medical School.
Simpson, W., Col. of Medicine, Newcastle.
Sheridan, N., Col. of Medicine, Newcastle.
Stevens, A. E., St. Thomas's Hospital.
Urwin, T. H., Col. of Medicine, Newcastle.
Varey, M., Col. of Medicine, Newcastle.
Walter, R. A., M.R.C.S, L.R.C.P., St. Bartholomew's Hospital.
Warner, A., St Thomas's Hospital.
Wreford, J., M.R.C.S., L.R.C.P., London Hospital.

The Mortality of Foreign Cities.

THE annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta —, Bombay 33, Madras 38, Paris 26, Brussels 18, Amsterdam 20, Rotterdam 24, The Hague 22, Copenhagen 19, Stockholm 18, Christiania 25, St. Petersburg —, Moscow 34, Berlin 17, Hamburg 18, Dresden 21, Breslau 28, Munich 23, Vienna 27, Prague 30, Buda-Pesth 27, Trieste 37, Rome 24, Turin 23, Venice 23, Cairo —, Alexandria —, New York 22, Brooklyn 17, Philadelphia 20, New Orleans 23.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

ACCEPTED PAPERS.

The following communications received since our last are hereby acknowledged:—

Some Therapeutic Omissions in Text-books on Diseases of the Skin, by John Kent Spender, M.D.Lond.

The Therapeutic Action of Organic Extracts, by R. W. Felkin, M.D., F.R.S.E.

The Period of Treatment of Spinal Caries, by Noble Smith, F.R.C.S.E.

The Treatment of Certain Forms of Advanced Cancer of the Uterus, by F. Bowreman Jessett, F.R.C.S.

Chronic Ovaritis, its Origin and Treatment, by W. J. Burleigh Robinson, M.D.

Dr. J. S. R.—The "puff" to which you refer in the local paper is obviously an indiscretion of a newspaper friend, for which it would be unjust to make the medical man referred to responsible. It is a piece of harmless nonsense which is equalled only by the writer's want of nice feeling.

Woodford.—The case speaks for itself, and it will be dealt with in our next. In future, please send all communications to the office in your division, it prevents delay. Your present note has to be remitted in this way.

L.R.C.P.Lond.—We cannot advise our correspondent as to which of the Medical Protection Societies is the best to join. The matter is one which he had better decide for himself after due inquiry among his friends.

Mr. W. H. S.—Our correspondent is not alone in holding the conviction that abuses exist. Indeed, we have been informed that the matter will shortly be brought under the notice of the House of Commons. A letter addressed to Sir Walter Foster, M.P., might be of service in the direction indicated.

THE ORIGIN OF THE ELECTRIC LIGHT.

Our Glasgow Correspondent says:—The Duke of Argyll had a distinguished visitor at Inverary Castle recently, and Lord Lorne had the amusing of him one day. He took him up to the dynamo house from which the Castle is lighted electrically, and showed him the wonders thereof. The man in charge was exceedingly courteous, and he stuffed the interested visitor, who did not seem to know much, full of the deepest electric lore. He fairly rioted in volts and ampères and such-like technicalities, and the visitor finally asked, "*Where the light itself originally came from?*" The question puzzled the operator for a second, but he ventured to express his conviction that it came from the water; and then Lord Kelvin, who was the visitor, and one of the best living authorities, smiled his placid smile, clapped his informant on the back, and said, "Well, my man, that's *one* thing you don't know any more about than I do."

Dr. H. Y. C. (Cheltenham).—We believe that only a very few subscribers withdrew their contributions to the Society for Promoting Christian Knowledge in consequence of the refusal of the Society to stop the circulation of Professor Franklin's book. Among these were Lord Coleridge and the recently imported Canon of Westminster, whose anti proclivities are not unknown to our readers.

Dr. Westgate is thanked for his communication, and the copy of the newspaper which he forwards. The matter shall receive attention in our next number.

Meetings of Societies, Lectures, &c.

Wednesday, May 2nd.

Metropolitan Hospital (Kingsland Road, N.E.).—At 5 p.m., Mr. Goodsall: Diseases of the Rectum. (Post-graduate Lecture.)

Obstetrical Society of London.—At 8 p.m. Specimens will be shown by Mr. Cutler, Dr William Duncan, Dr. Remfry, and others. Dr. J. Braxton Hicks: On Intermittent Contractions of Uterine Fibro-myomata, and in Pregnancy in relation to Diagnosis.—Dr. Remfry: Ligature and Division of the Upper Part of both Broad Ligaments, and the Result as compared with that following Removal of the Uterine Appendages.

Thursday, May 3rd.

Ophthalmological Society of the United Kingdom.—At 8.30 p.m. Living and Card Specimens at 8 p.m. Mr. Hartridge: A case of Scrofulous Keratitis (?). Papers:—Mr. Priestley Smith: On Periodical Testing of Eyesight in Schools.—Dr. A. W. Sandford: (1) Notes of Three Cases of Tubercle of the Iris; (2) A case of Double Optic Neuritis from Caries of the Sphenoidal Cells and Intra-cranial Abscess.—Mr. John Griffith: A Rare Form of Intra-ocular Melanoma.—Dr. James Taylor: Optic Neuritis in its relation to Cerebral Tumour and Trephining.—Mr. N. C. Ridley: Some Points in the Histology of Trachoma.—Mr. Simeon Snell: (1) Cases of Congenital Serous Cysts of Eyelids with Anophthalmos or Microphthalmos; (2) Osteoma of Orbit.

Royal Institution.—At 3 p.m., Prof. Dewar: The Solid and Liquid States of Matter.

Royal Meteorological Society and The Sanitary Institute (Parkes Museum, Margaret Street, W.).—At 8.30 p.m.. Mr. W. Marriott: Moisture, its Determination and Measurement.

Friday, May 4th.

West London Medico-Chirurgical Society (West London Hospital.).—At 8.30 p.m., Mr. W. H. Battle: Two cases of Traumatic Rupture of Liver.—Dr. H. Macnaughton Jones: Rest, Physiological and Therapeutical, in the Treatment of Eye Affections.—Mr. G. Charles Wilkin: Case of Epithelioma of the Ear treated by Injections of Pyoktanin (with specimen).

Saturday, May 5th.

Royal Institution.—At 3 p.m., Captain Abney: Colour Vision. (Tyndall Lecture.)

Monday, May 7th.

Odontological Society of Great Britain.—At 8 p.m., Mr. D Hepburn will open a discussion upon The Methods of Retaining Dentures in Edentulous Lowers. Mr. O. Fergus will exhibit A Dental Phantom.—Mr. Bland Sutton will show A Pus Cyst.

St. John's Hospital for Skin Diseases (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Loss of Hair.

Vacancies.

Cardiff Union.—Assistant Medical Officer. Salary £100 per annum, with apartments, attendance, washing, &c. Applications and testimonials to the Clerk by May 10th.

Fisherton Asylum.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

Huddersfield Infirmary.—Senior House Surgeon and Junior House Surgeon. Salaries £80 and £50 per annum respectively, with board, lodging, and washing. Applications and testimonials to the Secretary by May 7th.

Lewisham Union.—Medical Superintendent. Salary £275 per annum, with unfurnished house, washing, &c. An additional salary of £75 per annum as Workhouse Medical Officer. Applications and testimonials to the Clerk to the Guardians by May 10th.

London Hospital, Whitechapel, E.—Medical Registrar. Salary £100 per annum. Applications and testimonials to the House Governor not later than May 5th.

Stoke-upon-Trent.—(1) Visiting Medical Officer of the Workhouse; (2) Resident Medical Officer of the Workhouse. Salary of the former at the rate of fifty guineas, and of the latter £120 per annum, with board, washing, and furnished apartments. Applications before May 11th.

Western General Dispensary, Marylebone Road, N.W.—House Surgeon (unmarried). Salary £50 per annum, with board and apartments. Applications and testimonials to the Hon. Secretary by May 3rd.

Appointments

Inglis, E. M., M.B., Ch.M., L.R.C.P., L.R.C.S.Edin., L.F.P.S.Glasg., Health Officer for Kew, Victoria, Australia.

James, P., L.R.C.P.Lond., F.R.C.S.Eng., a Physician to the Wellington Hospital, New Zealand.

Jenkins, E. J., M.D.Oxon., M.R.C.P.Lond., M.R.C.S., Honorary Physician to the Sydney Children's Hospital, New South Wales.

Lamb, D., M.B., C.M.Glasg., Assistant Medical Officer to the City of Glasgow Fever Hospital at Belvidere.

Mansell, E. A., L.D.S. R.C.S., Honorary Dental Surgeon to the Liverpool Dental Hospital.

Massey, H. M., L.R.C.P.Lond., M.R.C.S., Government Medical Officer for the District of Hillgrove, New South Wales.

Quarry, M. H., M.B., B.Ch.Irel., Assistant Medical Officer to the Infirmary of the Parish of Lambeth.

Ryan, J., B.A., M.D., B.Ch., B.A.O. T.C.D., Medical Officer to the Hollywell District of the Shoreditch Union.

Sangster, J. J., M.R.C.S.Eng., L.R.C.P.Edin., Resident Medical Officer at the Adelaide Hospital, South Australia.

Smith, J. A., M.R.C.S., Medical Officer of Health for the Flockton Urban Sanitary District of the Wakefield Union.

Tresidder, E. S., L.R.C.P.Lond., M.R.C.S., Medical Officer to the Burrangong District Hospital, New South Wales.

Walsham, H., M.A., M.B.Cantab., M.R.C.P.Lond., Registrar and Pathologist to the City of London Hospital for Diseases of the Chest.

Weld, J. C., L.R.C.S., L.K.Q.C.P.Irel., Health Officer for the District of Hopetoun, Victoria, Australia.

Wilks, S. L. B., M.B., B.S.Lond., L.R.C.P., M.R.C.S., Medical Officer for the Grassington Sanitary District of the Skipton Union.

Births.

Bolster.—April 26th, at Nowshera, India, the wife of Surgeon-Major J. McM. Bolster, Army Medical Service, of a daughter. (By telegram.)

Tracey.—April 24th, at Willand, Cullompton, Devon, the wife of Henry Eugene Tracey, M.B., M.R.C.S., L.R.C.P., of a daughter.

Marriages.

Ayres—Haydon.—April 26th, at St. Mary's, Lambeth, London, Charles James Ayres, M.D., H.M.C.S., Mauritius, to Edith Clara, only daughter of the late George Henry Haydon, barrister-at-law.

Deaths.

Alexander.—April 15th, at Sinclair Terrace, Wick, of typhoid fever, Alexander Alexander, M.B., C.M.Ed., aged 45.

Blackwell.—April 22nd, at St. Andrews, M.B., James Hay Blackwell, Surgeon-Major, late H.E.I.C.S., aged 75.

Douglas.—April 25th, at his residence, Coolbawn, Warrenpoint, Co. Down, of pneumonia, Allen Edmund Douglas, M.D., F.R.C.S.I., J.P., son of the late Captain Edmund Douglas, R.M., aged 59.

Eddowes.—April 17th, at Pontesbury, Salop, William Eddowes, M.R.C.S.Eng., L.S.A., aged 83.

Lush.—April 28th, at Fyfield, Eastbourne, Wm. J. Hy. Lush, L.R.C.P. Lond., M.R.C.S., aged 43.

Marshall.—April 16th, at his residence, Kilmarnock, Alexander Marshall, M.D., L.F.P.S.Glasg.

ON INTERMITTENT CONTRACTIONS IN UTERINE FIBROMATA AND PREGNANT UTERUS IN RELATION TO DIAGNOSIS.

By J. BRAXTON HICKS, M.D.Lond.,
F.R.S., F.R.C.P.,
Consulting Obstetric Physician at Guy's Hospital, and St. Mary's Hospital, London.

IT may be in the recollection of some members of this society that in 1871, I read a paper, published in our "Transactions," vol. xiii, describing a fact, before overlooked, namely, that the uterus contracted and relaxed alternately at pretty constant intervals during the whole of pregnancy. In other words, that at intervals of about from five to twenty minutes, the hand could distinctly recognise an increase of its firmness, and then a recurrence to its ordinary state. That this could be observed without difficulty when the uterus was above pubes, but also that if low down or retroverted or retroflexed, it could be observed *per vaginam*. In this paper, as also in subsequent papers read before the Obstetric Section of the International Medical Congress, 1881, and following, I gave cases in illustration of the value of the knowledge thus afforded us as regards the diagnosis of pregnancy and other tumours complicating it, or independent of it. I also pointed out the physiological use of these contractions, the principal points of which I described in a paper read before the Royal Society, and published in its "Proceedings," 1878, entitled "On the Auxiliary Forces Concerned in the Circulation of the Pregnant Uterus in Woman." Before this society I also read a paper showing that the effect of these contractions was such on the abdominal respiratory wave (described by me in a paper read before the Medical Society, December, 1882, "On Tension of the Abdomen and its Varieties"), as to nearly obliterate the curves of the tracings, as shown by the gastrograph there described.

When my paper was read before the International Medical Congress in 1881, Dr. Matthews Duncan, in the discussion following, remarked that, "considerable subtraction must be made from the value of this diagnostic sign, because a soft fibroma without pregnancy, itself or its capsule or both, contracted quite as distinctly, and with as much change of shape as the gravid uterus." It does not appear whether Dr. M. Duncan himself observed this change. In a letter to the *Lancet* shortly after, I said that this might be the case, but that I had not, up to then, met with such a one, and that I thought it must be rare, and I remarked that I thought no one else had noticed it. In rejoinder, Dr. Herman pointed out that he had, in the *Obstetrical Journal*, 1880, published a case of fibroid tumour, in which he had noticed this varying density, and Dr. John Williams, in same number of the *Lancet*, Sept. 3rd, 1881, also called attention to a case he had passingly mentioned in a lecture "On the Periodical Changes which Occur in Fibroid Tumours," 1880. To this, I answered that, although I had not hitherto observed the change, yet I had great confidence in these gentlemen's powers of observation that I was prepared to assent that so far as these two cases went, this change did occur, but that further observations were required before we could accept the phenomenon to be of common occurrence. I then proceeded to show how far the power of contraction in fibroids interfered with the value of the contractions of a pregnant uterus as a means of the diagnosis of pregnancy. This I will not now repeat as I shall discuss this point later on. It was not till about one and a half years ago that I had an opportunity of seeing a case which was parallel to the cases of Drs. Herman and Williams.

Own Case.—It was in a lady, about 43, of a highly nervous temperament, becoming almost maniacal at menstrual periods. She had lately increased much in the size of abdomen, and the menses had been for four or five months irregular, absent for two months, but too frequent the latter portion, once or twice profuse. I found a tumour rather to right side as high as umbilicus, firm and prominent in centre. During my examination, I became conscious that it had become less dense and prominent. This variation was clearly marked during a prolonged examination, and I recognised that if she was not pregnant, then it was a fibroid simply, or fibroid with pregnancy, for the feel of the mass was not that of an ordinary pregnant uterus during its relaxed condition, and besides this, there was an irregularity in its outline. I consequently made examinations from time to time, but detected no increase of size corresponding to normal pregnancy, and the menses returned nearly regularly after some time had passed. It was evident that there was no complication of pregnancy, but a fibroma of the softer kind that still remains.

It is due to the above-named observers to corroborate their experience, and it is also due in the interest of our scientific advance that we should recognise that occasionally soft fibromas of uterus do undergo alternations in density. The bearing of this fact on our diagnoses is the next point that has to be considered.

As in pregnancy we have amenorrhœa as a most common condition, so in fibroma and its varieties there is very rarely absence of menses, but the most common condition is menorrhœa and metrorrhagia. There is, however, a difference in the relative frequency of these opposite conditions, Amenorrhœa is less frequent in fibroma than menses, menorrhagia, and metrorrhagia are in pregnancy of all kinds. If we exclude, however, the abnormal conditions of pregnancy, the infrequency of the continuation of the menses during the first half of gestation will more nearly compare, though slightly in excess, with the infrequency of the amenorrhœa in cases of fibroma.

When, therefore, we are desirous of diagnosis of tumours reaching from the size of a three and a half months' pregnancy to that of full term, and even over, it is in the unusual cases of fibroma with amenorrhœa, and in the more frequent though relatively to ordinary pregnancy much less common, cases of pregnancy with periodical appearance of blood that we have to call in other diagnostic aids.

But in forming diagnoses by the doctrine of probabilities, one might say in a case of enlargement of the uterus after the absence of the third menstruation, the size of the uterus being in accordance with that of the uterus in normal pregnancy, the health of the woman continuing good. If we decided that she was pregnant we should be right in 95 per cent.

For by the end of three months the temporary checks are most commonly rectified, and the accompanying swelling of uterus has subsided, while almost all the enlargements of the uterus other than by pregnancy are not only not coupled with amenorrhœa, but most commonly by menorrhagia and excess.

But careful consideration of condition of the uterine contractions in pregnancy and with fibromas will show how far these assist us in forming diagnosis.

One might say at the outset that the rate of frequency in these contractions will not help us, because in pregnancy the period of their occurrence is unequal. But in the case of fibroid I believe it is yet to be determined whether they occur spontaneously, or whether they are set in motion by the handling. In pregnancy they certainly occur irrespective of the handling, one often finds the uterus already to be firm and tense, and then relax during the examination.

Now when the uterus relaxes in normal pregnancy, although it was impossible to feel the fœtus by palpation before, yet when the relaxation occurs the fœtus is generally to be made out not only by its movements, but by "dipping or "bobbing" as some have called it; in the same way as one feels for solid through fluid in the abdomen, or a solid in an ovarian cyst. The tips of the fingers press the parietes firmly on to the uterus, and impress its walls steadily; then by a slight quick movement the fingers press still deeper, and if a fœtus be there a momentary resistance is felt, varying according to the size of fœtus and its mobility. If much fluid be present there the feeling is but very momentary, for the fœtus recedes as in ballotment. Now it is but rarely in normal pregnancy, but that the fœtus cannot be thus detected either externally, the woman placed dorsally or laterally, or *per vaginam.*

This recognition of the fœtus can be obtained in many of the few cases I have before alluded to where some kind of blood discharge is met with in pregnancy, limiting thereby to that extent their relative number.

But there is a different feeling generally given to the hand in the case of a large relaxed soft tumour, still more evident in the smaller and firmer tumour, and although I would not press this point too far, yet I may say that the yielding of a hollow body is different to that of the solid though elastic; in the one the resistance is only just beneath the finger, while in the other it continues to the centre.

But if we now take those large soft uterine tumours which exhibit the intermittent contractions, how very few of them will really make diagnosis difficult? In nearly all will be a longer history of menorrhagia, of growth, and noticeable bulk than in pregnancy, and particularly of the abnormal kinds of vesicular mole and hydrops amnii: and again in the normal pregnancy of equivalent size, the presence of the fœtus will almost always be made out by palpation, if not by other signs; particularly by the development of the os uteri, which would be very different in pregnancy. Still if the fœtus could not be felt during the relaxed state, I admit our diagnosis must be difficult judging solely by the intermittent action. But such cases are very uncommon.

In cases of vesicular mole the physical condition imitates very closely that of a soft fibroid, and as no fœtus is present, the existence of contractions will not help us to solve the difficulty, though of course there are other circumstances which enable us to make out the case, such as the short history, the state of os, the extrusion of vesicular bodies.

In hydramnios, however, besides the also rapid history, we have sensible fluctuation, and with care the presence of the fœtus to guide us, so the case becomes one of differential diagnosis in respect of ovarian tumour and other cysts, in which case the contractions will prove at once its uterine nature.

However, the cases in which the greatest difficulty of diagnosis between fibroids and pregnancy occur is in those abnormal conditions of pregnancy called carneous mole and early death of fœtus, with hæmorrhage, because in these there is great similarity both in physical characters and also in symptoms; not that we have the intermittent contractions to help us, for often the uterus remains firm as a hard fibroid for some weeks together. Though here again the recent character of the history is unlike that of a fibroid tumour, and generally commenced with an absence of one or two periods. These cases form but a small percentage of the total cases of pregnancy. The following cases illustrate the difficulty which may arise very occasionally:—

A lady had been suffering very severe paroxysms of pain just above pubes, many times in the day for a few weeks. She was hardly able to move at the time. She had not menstruated for four months. On examination I found the uterus enlarged to a size corresponding in pregnancy to the usual size. It was very hard and solid, the os not particularly enlarged, and the mass resembled a dense fibroid. There was no history of previous menorrhagia. There was nothing about the os to indicate closure, and I concluded she was pregnant and the pain was owing to the normal contractions exaggerated, probably by something abnormal in the ovum. I saw her at intervals of a week four times, finding the same conditions of pain and hardness. My examinations of the abdomen were prolonged each time in hopes of getting the relaxed state, but without success, till at the end of the fourth time, just as I was giving up, the whole uterus relaxed, in other words that which was so hard and solid, so long, had almost disappeared. Therefore I pronounced in favour of pregnancy; and so it turned out, in due course a healthy fœtus was born. However, when the uterus keeps continually rigid, it is generally in consequence of irritation produced by some disease of ovum generally accompanied by effusion of blood into placenta.

In cases of the complication of uterine fibroma and pregnancy, it has been remarked that the difficulty of diagnosis would be increased. But this opinion has been given without due reflection. The difficulty of making out this state will always be great in the early months, but unless the uterus be more than half-way round involved in the tumours, about the fourth month, one will be quite able to distinguish a difference in substantiality at least, if not to detect the fœtus, and then as the uterus contracts, so we shall notice that the more solid and relaxed portions are all included in the same body; and this and the converse being repeated at intervels, we gain the information of the existence of fibroids and also of pregnancy; and also we are able to note the point I have already alluded to, namely, the distinction between the feel of a relaxed fibroid and that of a pregnant uterus.

In cases of differential diagnoses between two tumours, say uterine and ovarian, we can utilise the contractions whether it be a fibroma, or pregnancy or both, recognising the one altering in firmness as uterine, the other as ovarian, same in an uterine tumour, and hydronephrosis, or in cases of extra-uterine to distinguish a pregnancy uterus from the sac.

It must be remembered that we do not in practice apply the test of this alternate action of the uterus till we had taken the history of the case, and before we approached the idea of pregnancy we should have excluded a good number of the cases to which I have alluded above.

And so, whilst we admit that a certain deduction has to be made from employing these contractions as absolute evidence of pregnancy, we find that they may be used in a large majority of cases, either as a distinct proof of pregnancy or in corroboration of other signs, or in differential diagnosis of abdominal tumours; and it is a point of much importance that we should have additions to the direct signs of pregnancy, for I have for many years taught that the secondary signs and symptoms are scarcely worth considering in the presence of the opportunity of direct evidence derived from the examination of the uterus and its contents.

THE PERIOD OF TREATMENT OF SPINAL CARIES.

By NOBLE SMITH, F.R.C.S.Ed.,

Surgeon to the City Orthopædic Hospital, and Surgeon to the All Saints' Children's Hospital.

I have elsewhere described the treatment of spinal caries as carried out at the City Orthopædic and at the All Saints' Children's Hospitals, and have upon several occasions described the almost uniform success which has attended this plan of treatment.

I propose now to discuss the question which often arises as to the length of time during which treatment must be continued before we may expect a cure of the disease, and also the time when the patient will be able to dispense with mechanical support. These are points of very great importance, in which every patient or his parents or friends are greatly interested.

The decision upon these questions depends very much upon the peculiarities of each case.

We may consider the subject from two points of view:—

1. *Period of consolidation of the diseased bones.*
2. *Period of time during which it will be necessary to continue mechanical support.*

1. Period of Consolidation.

The three chief items for consideration are:—

(*a*) General health of the patient.
(*b*) Extent of the deformity.
(*c*) Progress of the case.

(*a*) I think it may be laid down as a rule that, given a patient who is apparently robust, and in whom the disease is presumably a local affection, and where the degree of deformity is moderate, the shortest time in which we may expect complete consolidation of the diseased vertebræ is one year. I would consider this year to commence at the time of complete cessation of pain and all other active symptoms, such as high temperature or spasmodic contractions of the limbs. This is the most favourable result, as regards time, we can expect in ordinary cases, the only exceptions being perhaps in cervical caries and in some cases of lumbar caries.

In a case of cervical caries which I have recorded a cure seemed to have been brought about in six months, but I doubt the expediency of acting upon such a result.

Upon commencing treatment we depend much upon the thorough carrying out of our directions, and it not infrequently happens that directly pain has been subdued, and all acute symptoms have subsided, the patient believes himself nearly cured and able to return to a great extent, to his more active occupations.

If this course be taken some of the former symptoms return, and many weeks or a few months may pass before he realises the absolute necessity of greater care.

Here the commencement of the year must date from the period when the patient has learnt how to modify his movements and to so adapt his habits that pain and other acute symptoms are absolutely subdued.

In some instances, from the commencement of treatment, notwithstanding our utmost efforts, and the utmost efforts of the patients, it will be several weeks or longer before we can subdue the active symptoms.

During progress towards recovery many things may happen to retard the improvement, an illness, a sudden slip or fall, a severe shaking in a carriage, or a sudden twist of the body, as in turning round quickly. Any of these incidents may seriously prolong the period.

There is a great difference in patients. Some will readily adopt the principles of care, maintaining a rigid spine whatever they may be doing; going about with caution and steadiness; doing everything in a deliberate manner; never sitting down in a chair suddenly with a jerk; never looking round quickly; never bending forwards energetically.

These patients may take plenty of exercise, moving about freely, but always discreetly and carefully, always keeping their spines rigid, being guided by the action of the supporting apparatus, and never trying to resist it.

Others do not take readily to these habits. They are too graceful in their movements, too spasmodic in their dispositions, and are frequently bringing back pain or discomfort by their inconsiderate actions. Then we meet with individuals, and they are numerous, who are ever wanting to test their progress; just trying if the pain can still be produced by some particular movement, and never contented to keep from all actions which have previously produced discomfort.

These irregularities may retard the progress of consolidation, and thus prolong the period of cure. The patients with whom we have the greater difficulty are those who suffer little or no pain, with them we must use our discretion as to their actions.

If we consider the period of a year as the shortest time in which a robust patient can get well, so we must increase that time in accordance with the general deterioration of the patient's health. When there is general tuberculous infection, the ultimate result must obviously depend upon subsidence of the general symptoms, or, in other words, upon the improvement of the patient's constitutional condition.

Notwithstanding the truth of this assertion, we often see carious spines consolidate, although tubercular disease is progressing elsewhere. Tubercular meningitis may cut off a patient in whom good progress has been made as regards the caries, and we may even find consolidation of carious vertebræ in patients who die from this or other tubercular disease. When tubercular disease has become general, it is useless to discuss the length of time necessary for consolidation of a carious spine, the general health of the patient being of the first importance.

(*b*) *Extent of the Deformity.*—If the spine is thoroughly supported, and there is a moderately severe angular deformity, other symptoms being favourable, we may consider a year a fair time for consolidation, but if there be indications of a great loss of bone, and especially if the rigidity has given place to undue flexibility, then we know that a space exists which has to be filled up; and that several years must elapse before the repair can take place, and the new bone become perfectly consolidated. In such a case the surgeon may consider it desirable to try and approximate the diseased bones, but I do not think this would be a judicious thing to do. Sometimes a patient has done this for himself, and produced a terrible deformity, as shown by a specimen in St. Mary's Hospital Museum.

This approximation of the diseased bones might expedite the period of consolidation, but we can hardly suppose that anyone, in order to save a few years of care, would submit themselves to an increase of deformity.

(*c*) *Progress of the Case.*—Whatever our opinion as to period of time may be, upon commencing treatment, we ought to be always ready to modify it in accordance with the progress of the case. Experience teaches the surgeon to be most guarded in giving a prognosis as to time. In a very favourable looking case there may be a large abscess existent which is gradually approaching the surface, and which will ultimately have to be opened.

Abscesses may greatly prolong the period of treatment, so that no definite period can be safely depended upon. It may be further stated that other complications, such as paralysis, will necessarily prolong the period before a recovery can be expected.

2. THE PERIOD OF TIME DURING WHICH IT WILL BE NECESSARY TO CONTINUE MECHANICAL SUPPORT.

This must depend upon the degree of deformity. It is obvious that until complete consolidation of the diseased bones has taken place, and all symptoms have disappeared, the apparatus must be worn.

When perfect consolidation is assured, the further use of the support will depend upon whether the spine is sufficiently upright or not to support the body without the latter giving way from its mechanical inefficiency. If the deformity is very considerable, some support will always be needed if an increase is to be prevented. Under these circumstances, the patients feel so much comfort from wearing the apparatus that they do not think of giving it up.

It is not the part of the spine which was diseased which would give way, but the sound parts above and below.

In slighter degrees of deformity it depends upon the strength and activity of the patient, whether he can maintain his erect position or not without his support. Sometimes a partial wearing of it, say every other day, or once a week, or when laboriously employed, may be desirable, or a more simple apparatus may be used.

ON CASTRATION IN FEMALES: (a)

ITS FREQUENT INEXPEDIENCY AND THE SIGNAL ADVANTAGES OF CONSERVATIVE SURGERY IN THESE CASES

By C. H. F. ROUTH, M.D., M.R.C.P.Lond.,
Consulting Physician to the Samaritan Hospital for Women.

PART III.

MODES OF OPERATION ON THE ANNEXES.

IN a remarkable paper published by Dr. Doleris in the "Nouvelles Archives d'Obstétrique et de Gynæcologie," vol. vi, p. 401, on the Abuses of Castration, a paper in sequence of a former one on Useless Mutilations, &c. He refers to the extraordinary number of cases in which such castration, *i.e.*, the removal of the annexes of the uterus, occurs in France, and gives the following table :—

Here is a total of 511 performed by 7 operators by laparotomy :

Richelot .	. 170	Le Dentu	. 34
Terillon .	. 140	Routier .	. 22
Bouilly .	. 70	Segond .	. 17
Doyen (de Reims)	58	Total	. 511

Richelot's cases occurred in 2½ years ; Doyen's in a town of 100,000 inhabitants. This number of operators does not include seven other operators of distinction. These operations, he adds, are practised in 45 institutions where surgeons carry on the service, so that M. Doleris believes that the number should at least be reckoned as 10 times more frequently done than above statistically stated, *i.e.*, over 5,000.

And yet Dr. Doleris asserts it as his conviction that 8·10ths of these poor women could have avoided this radical operation. Dr. Doleris states further that out of about 300 cases observed in 3 years, he found about 50 in whom castration might have been reasonably practised, but that every day he found that he could cure them as effectually by other measures.

It is unfortunate for those who remove the annexes that the mortality is really considered as a negligable quantity, because so trifling.

These operations, Doleris tells us, are practised in France for ovarian folliculitis, catarrhal salpingitis, pelvic cellulitis, and true hysteria.

But we learn that the removal of the annexes is often performed in these realms, when the organs removed are perfectly healthy. Mr. Lawson Tait gives us his authority for this statement. In the *Lancet* for Feb. 7, 1891, p. 293, Mr. Tait in a lecture given before learned doctors, described a visit he had paid to one of his disciples, who triumphantly brought out two dozen appendages in bottles, which in almost every instance were free from guile.

In America, in the discussion upon Dr. Polk's paper (see "Transactions of New York Journal of Gynæcology and Obstetrics," p. 728, for August, 1893), Dr. Williams, of Baltimore, says : "For the last three or four years I have received a large number of tubes and ovaries in Baltimore, in fact, I have received all that were removed by five different operators for examination, so that I am able to say what few other men can, that a very considerable number of the operations are done absolutely with no justification. As the result of my work, covering at least 300 tubes and ovaries, that in at least 5 per cent. of the cases there was absolutely no anatomical ground for removing them. . . . I have seen a considerable number of young women who have had their ovaries removed for dysmenorrhœa, and in the vast majority of these cases there is no reason for it.

Dr. Wathers, speaking of Dr. Polk's paper, said he thought it would have a good effect upon those members of the profession who were so fond of removing the ovaries, whether they were diseased or not. He had seen ovaries and tubes removed in which you could not see one particle of disease, tubes a little smaller than normal.—*Ibid*, p. 729.

MEASURES TO BE TAKEN WITH DISEASED ANNEXES.

We come now to the practical part of this paper. What are we to do with diseased annexes ?

I.—The complete or partial extirpation of the annexes.

1. Complete extirpation the easiest and simplest, corresponding to the spaying of animals.

2. Partial extirpation.

A. Dr. Polk, partial resection of tubes, and of ovaries, and cutting or tearing adhesions, and replacing portions so treated within the abdomen.

B. Dr. Barrow's partial amputation of tubes and returning the healthy part in the abdomen.

C. Professor Pozzi, partial resection of diseased parts of ovary, the cut edges being brought together, if healthy, and stitched, or ignipuncture of ovary if cystic fixing ostium of tube to ovary.

D. Dr. Martin, also practises resection of the ovary in like manner, but without ignipuncture, and then resection of diseased part of tube and formation of a new ostium.

E. Salpingotomy as taught by Dr. Skutch, *i.e.*, a small piece of tube being removed and the parts brought together in cases of hydrosalpinx.

In all these modes of operation abdominal section must be performed to expose the annexes.

II.—Cases in which the treatment is carried through the vagina or rectum.

1. Dilatation and curettage of uterus.

2. The special treatment of gonorrhœal cases by electricity.

3. The relief of abscesses by the use of the aspirator.

I. *Complete Extirpation* has been largely recommended, and on both sides, even when only one annex is diseased. The reason alleged for doing so is that if one annex is diseased, the other soon will be. The objection to this method, however, is that although the easiest plan, it is not invariably necessary. For the remaining ovary may not become diseased, but enlarge, and by its increased size compensate for the loss of the other, and so many such women have become mothers. We do not remove both ovaries in cases of ovariotomy, and many of those so operated on have subsequently become mothers. I do not say complete extirpation may not be sometimes necessary, but even on this question gynæcologists would differ. Some, as Segond would say, do it but with hysterectomy and deprive a woman of her womb, which, if retained, is often a source of discomfort—forgetting the greater mortality. But this question does not really concern us at present.

(a) Paper read before the British Gynæcological Soc., April 19, 1894

II. A. *Partial Extirpation.*—To Dr. Polk I think, of New York, we must give the honour of having put this mode of operation boldly before the profession, and very unanimous should be the praise tendered to him for having defined a more merciful and a wiser mode of action. It is true he opens the abdomen, and looks in, but he respects the motherhood and the feminity of the poor sufferers on which he operates, and mutilates as little as possible. He takes up the axiom of another great gynæcologist, whom he also quotes emphatically, p. 653. I take it for granted, says Schroeder, that the essential matter in this question of the ovary, is the maintenance of menstruation and ovulation, because of its effect upon the physical and mental well-being of the patient.

1. *As regards Tubes.*—Polk recommends retention of the tubes in thickening after acute inflammation, unless the uterus be the cause. If so, it must be at once cleansed, curetted, and packed with gauze.—P. 651. Delay extirpation of tubes. If the tube be not dis-distended and is closed by recent lymph, he opens it, approximates the outer and inner coats, washes it out with plain water, and returns it to the pelvis (p. 652), but he removes all tubes distended with muco-pus, blood or sero-fluid, even to the very cornua uteri.

2. *As regards Ovaries.*—Generally these should be removed if the ovaries be sufficiently diseased. As a rule he removes both ovary and tube. But should the ovary also be removed with the tube, if the tube only is diseased? Polk replies in the negative. Remove the tube, but leave the ovary, even if the case be one of pyo-hæmato- or hydro-salpinx, and quotes ten cases so operated on, and with good results, one becoming pregnant subsequently.

3. *As regards Adhesions.*—If these imprison the ovaries and tubes, they will destroy their functions. If the adhesions can therefore be cut, or torn away safely, this should be done, and the organs will regain their integrity in many cases.

Dr. Polk's Modus Operandi as regards the Uterus.—In every case the uterus should be dilated, curetted with a sharp curette, and then packed up with as much gauze as it can possibly be made to hold. This clears the field.

As regards the Operations.—While the ovary is merely the seat of small cysts, *ignipuncture* with a fine cautery point is the best procedure, or with larger cysts enucleation and subsequent cutting away portions by a V-shaped incision. In the removal of a tube, or a portion of it, act as you would in a case of removal of a portion of intestine, &c. At the date of this paper Dr. Polk had operated in some one or other of these conservative ways in 80 cases, and these cases were for the most part again seen after periods of six months or two years, and he states that in all, except seven, excellent therapeutic results were obtained.—P. 654.

B. AMPUTATION OF PART OF TUBE—DR. BARROW'S MODE OF OPERATION.

In a paper by Dr. Charles Clifford Barrows, of New York, on the conservative surgery of the uterine appendages (*American Journal of Obstetrics* for December, 1893), after a short review of the more radical treatment by extirpation of the tubes, he refers to the paper by Dr. Polk, who treated diseased and adherent tubes and ovaries and cured them by more benevolent measures (*New York Journal of Obstetrics, &c.*, Aug., 1893). It was clear that under the name "Cellulitis" catarrhal salpingitis was cured every day by routine means, and that by simple breaking up of the adhesions and washing out a tube in catarrhal salpingitis, when even swelled to the size of a finger. In eight cases at different times where the inflamed and adherent appendages were freed from their adhesions, the fimbriated extremity of the tubes were opened. The tubes were washed out, and with the ovaries returned to the abdominal cavity and the patients were cured. Although most of his hearers maintained their preference to non-interference or complete extirpation, Dr. Barrows insisted upon a more conservative treatment and one founded on the *fons et origo* of its pathology.

All persons (he says) admit that salpingitis and ovaritis as a rule originate from the extension of some inflammatory condition of the uterus, or its lining membrane. Dr. Polk concludes from this fact that, irrespective of what you may do with the appendages themselves, the original source of infection must be removed, and to do this he advises curetting and firm packing of the cavity with gauze. This cures at once not a few cases of salpingitis.—*Ibid.* for Feb., 1892.

Now, Dr. Barrows adopts the same plan, either before or at the time of celeotomy, as it is quite possible and more convenient to perform these two operations synchronously. Indeed, he states that he has on more than one occasion curetted, packed the uterus, repaired lacerations of the cervix and perinæum, and resected the tubes and ovaries at the same sitting, all within one hour, thus avoiding a second etherisation.

By resection or amputation of the tubes Dr. Barrows means the cutting off of the diseased abdominal end of the tube, not the removal of a portion of the wall of the tube, the apparent healthy portion being returned to the pelvic cavity. In certain cases of pyo-salpingitis the tube may be amputated at some distance from the cornu of the uterus, and the formation of an artificial ostium abdominale may be so completed. In some instances he has noticed the tube which contains the pus is closed firstly at the extreme end of the infundibulum by adhesions with surrounding parts, ovaries, intestines, &c., but secondly it is also closed at a point about a half to an inch or more in length from the uterine cornu. It is in this sac that the pus accumulates. In the inner portion of the tube the aperture is patent, and any pus there formed is discharged by the uterus, but far more frequently neither the mucous, serous, or muscular coats of this portion are inflamed. It is in these cases where we have a healthy ovary, and the fimbriated extremity of the tube is not adherent to it, that he amputates the healthy portion of the tube, washes it, and slits it up a little way, and unites the serous and mucous coats of it by fine catgut ligatures, bringing the new ostium thus formed in close apposition to the ovary. The uterus may thus be curetted and filled with the gauze, all painful symptoms disappear even during menstruation.

Of the completeness of the cure Dr. Barrows had an opportunity of convincing himself in a patient who came to him for hernia, and on whom he had operated a year previously, removing a purulent tube and ovary from the right side, breaking up the adhesions on left side, resecting the tube and about one-third of ovary, and on examination he found the latter in apparently a perfectly healthy condition.

Dr. Barrows concludes his very interesting paper by a tabulated account of 18 cases so treated, besides a 19th not included in the table; 6 were cases of pyo-salpinx in which the tube was amputated and a new ostium made.

C. PROFESSOR POZZI'S CONSERVATIVE TREATMENT.

Professor Pozzi insists as one of his preliminary points that salpingitis being an extension from the uterus of disease, the uterus must be treated, and this by curetting, cauterisation and electricity, but this he believes will fail the moment that pus begins to form, and when in chronic cases the tubal walls have thickened and the fimbriæ united. He speaks doubtingly, however, as to massage, lest it should induce rupture, and electricity is equally hazardous except in neuralgic cases. He also opposes dilatation of uterus and internal ostium of the tubes, because it provokes neighbouring inflammation, and it does not open the os so as to allow free exit from the tube. Pointing next to the magnificent results obtained by resections of bones and joints in surgery, he concludes that there is abundant evidence that this may be done for the tubes. But he limits his operation. Cases which after laparotomy display profoundly disorganised appendages, a pyosalpinx with abscess of ovary, or complete cystic transformation of ovary and parenchymatous alterations of the tube, these must be removed in totality. But in hydrosalpinx with relative integrity of the ovary, cysts only the size of a pea, or an intact and permeable tube with diffuse ovaritis, sclerosis, or limited longer cysts, or microcystic degeneration, conservatism may be adopted. In the first case partial resection of the ovary may be done; in the second we may perform salpingostomy, *i.e.*, re-establishing an ostium by partial resection of the Fallopian tube.

The general rule Pozzi gives is that wherever the Fallopian tube is healthy and the ovary alone diseased we must endeavour to preserve a part, and only at the last extremity resign ourselves to a total extirpation.

The plan originally adopted by Pozzi was, first having ascertained that the tube was perfectly permeable by a stylet down to uterine cavity, the ovary was seized and a piece of it removed by a cuneiform section. The parts were thus brought together by catgut sutures. If the ovary is affected with microcystic degeneration, any portion of it, and frequently the hilum, is intact and not so affected, it is spared and the diseased portion alone removed, and thus the ostium of the Fallopian tube is fixed upon the ovarian stump by a few points of suture, salpingostraphy, and thus placed in position to receive the ova. More lately Pozzi has still further modified his *modus operandi* by opening all these small cysts by the knife, or actual cautery, which in itself often causes an energetic melting away of the chronic inflammations.

His remarks in his own words may be here added. He has practised complementary hysterophy upon only one of his six patients. Upon 4 he practised salpingorrhaphy, or suture of the Fallopian tube to the uterine stump, which he has also done in some broken adhesion cases. In 5 out of the 6 cases he removed the appendages in the opposite side.

To summarise: Fourteen women on whom he practised conservative operations on the ovary recovered, were cured, or immensely improved. In each case menstruation recurred, and one became pregnant.

MARTIN'S CONSERVATIVE OPERATIONS ON OVARIES, ETC.

D. Martin (*Deut. Med. Woch.*, July 27, 1893, Epitome B, Association Journal, Sept. 9, 1893) has also adopted conservative measures.

1. Resection of the ovary. Usually bilaterally diseased but sometimes only circumscribed cystic disease may be found in the other ovary. Under these circumstances, should the entire ovary be removed? His answer is in the affirmative, if there be no healthy tissue left, and if the process be suppurative, but not in some other cases. He refers to 27 such cases with one death. Two of these relapsed, but of the 24 remaining 8 bore children. Ignipuncture has been used by Dr. Pozzi, but Martin is satisfied with incision and stitching up.

2. Again, resection of a stenosed tube, the other being removed for disease. Here it may be more difficult to recognise the character of the disease. The contents of the tube must be carefully examined, if they are turbid or unmistakably purulent, or if the mucous membrane be ulcerated, the tube must be removed, otherwise resection with the formation of a new ostium may be practised. If any doubt exists, the whole appendix should be removed. Of 40 cases with 2 deaths only 4 were not cured or considerably improved, only one became pregnant, but 12 were unmarried, and the husbands of some others were asthenical or had had gonorrhœa.

Thus we have a mortality for the first class of cases of 3·7 per cent. and in the second class of 5 per cent.

Selected Prescriptions and Therapeutic Notes.

126.—An Application for Enlarged Glands:—

℞ Iodoformi;
Bals. Peruviani, āā ʒj;
Colodii, ℥j.

M. To be painted over the swellings every night.

127.—For Urticaria:—

℞ Liq. calcis;
Aq. lauro-cerasi;
Glycerini, æq. partes.

M. The skin is dabbed with some of the lotion, and then covered with a thin layer of cotton wool.—BOURDEAUX.

128.—For Fœtid Diarrhœa in Children:—

℞ Calomel, gr. iss;
Zinci sulpho-carbolatis, ʒijss;
Bismuthi subnitratis, ℥ij;
Pepsinæ, gr. xxx.

M. Divide into twelve powders. Three powders daily for a child of one year.—DR. E. TOMKIN.

129.—For Laryngeal Phthisis:—

℞ Iodoformi. ʒj;
Pulv. acid. borici, gr. vij;
Pulv. calcii phosph, ʒijss.

M. Morning and evening the throat should be insufflated with the powder.—PROF. COZZOLINO.

130.—A Mixture for Asthma:—

℞ Chloroformi, ʒj;
Etheris, ℥iss;
Syr. acaciæ, ʒj;
Tinct. cardamon. co., ℥j.

M. A teaspoonful to be taken every half-hour until relief is obtained.—*L'Union Medicale.*

131.—Pills for Chronic Bronchitis:—

℞ Ammonii chloridi, gr. xv;
Ammon. carb., gr. xv;
Pulv. ipecac, gr. iij;
Morph. hydrochloratis, gr. j;
Mucilaginis acaciæ, q.s.

M. Divide into ten pills, one to be taken night and morning.

THE Improvement Commissioners of Stourbridge have passed a resolution adopting the Notification of Diseases Act (excluding measles and whooping-cough). At the meeting at which the resolution was agreed to t was pointed out that there was now only one uthority in the county of Warwick which had not dopted the Act.

Clinical Lectures

CASES IN PRIVATE PRACTICE.

Case of Poisoning by Corrosive Sublimate by Absorption through the Unbroken Skin.

Under the care of Dr. Ed. F. Stephenson,
Ballyduff, Lismore.

Patrick Keefe, of Tubbernahulla, co. Waterford, æt. 28, labourer, suffered from varicose veins, and had a "few yellow pimples" on the calf of right leg. An ulcer had formerly been on the right leg also, but was now quite healed.

On April 1st he consulted a man named Donovan, whose father had gained some notoriety for the treatment of "tethers." Donovan was considered a good man also to cure "tethers," but not quite so skilful as his father. Donovan, having looked at Keeffe's leg, said he had "tethers," and that he "would cure it in half a minute with a couple of rubs." Keeffe promised to pay 10s. if cured. Donovan then mixed something with butter, and applied it with a knife to both of Keeffe's legs; the reason for applying it to the left leg, which had no pimples, being to prevent it getting "tethers." This occurred at 11.30 a.m. He then directed Keeffe to stand before the fire, where he remained for over an hour. The legs soon got hot, burning and very painful. Keeffe then put on bandages, that he was in the habit of wearing wet with lead lotion, on his legs. He left Donovan's house at 1.20 p.m., feeling very weak, with pains in his legs shooting up to the hips. At 2.30 or 3 p.m. there was violent purging. The bowels moved five or six times before he reached the house in which he lived. He also vomited on way home. At 4 p.m. he noticed lumps in his groins, and at 6 p.m. he passed blood by the bowels. I was called to see him, and reached the house at 8.30 p.m. He was then very weak and exhausted, and suffering considerable pain. On removing the bandages I found the skin of both legs, where the butter had been applied, whitened and greatly corroded, the surrounding skin being hot, burning, and inflamed. The lymphatic glands in the groins were enlarged and very tender. Having washed the legs, I quickly got the patient to bed. The prominent symptoms were: severe rigors, violent purging and tenesmus, the evacuations consisting of blood, suppression of urine, none having been passed since morning; temperature 100·4° F., pulse 68, weak and irregular.

Ordered: Pulv. opii, gr. j, in pill every three hours; poultices of linseed meal to loins.

On April 2nd the more prominent symptoms were: burning pain in stomach, with tenderness over epigastrium and colon, nausea, retching and vomiting (during night), purging, the evacuations consisting of blood and shreddy mucus, great thirst, salivation, expectoration of stringy mucus. The patient complained of having suffered great pain when passing water the first time during the night; temperature 99·3° F., pulse 68. Ordered:—

℞ Potass. iodidi, gr. iij;
Potass. chlor., gr. v;
Aquæ, ℥ss.
To be taken every four hours.

4th.—Stomatitis, with fœtor from breath, red line on gums, cramps in thighs. Complained of difficulty in passing water once during the night. Melæna and pains ceased.

6th.—Patient doing well; temperature normal, pulse 60.

10th.—Patient removed to Lismore Hospital, where he continues to improve under the care of Dr. P. R. Dennehy.

Donovan was arrested on April 2nd. He was charged at Petty Sessions in Lismore with having "unlawfully and maliciously inflicted grievous bodily harm" on Keeffe. The magistrates refused to receive the informations against him on the grounds that there was no *malice* shown. The prisoner was thereupon discharged.

Since writing the above, I have been informed of another case in which Donovan attempted to cure "tethers."

—— Brien, a boy, æt. about 12, living near Kilorth,w co. Cork, suffered from some form of skin disease. Donovan was brought to see him by the boy's father, said he had "tethers," and rubbed him all over with "butter," on Feb. 24th, 1894. The boy died on Feb. 28th. I have been unable to get further information about this case as the boy did not reside in my district. No inquest was held. In the interest of the public, and in justice to Donovan, in view of Keeffe's case, it would surely be desirous that the boy's body be exhumed, and the cause of death ascertained.

Transactions of Societies.

OBSTETRICAL SOCIETY OF LONDON.

Meeting held Wednesday, May 2, 1894.

The President, Dr. G. E. Herman, in the Chair.

FIBROSIS OF OVARIES.

Dr. Remfry showed two ovaries removed by Mr. Lockwood at the Great Northern Hospital from a woman, æt. 32, who had had ascites for eighteen months, for the relief of which she had been tapped several times. Neither heart disease nor albuminuria were present, but the liver was enlarged to about 1½ inches below the ribs. On making an exploratory incision nothing amiss was discovered inside the abdomen except the curious-looking ovaries, which were pale in colour, large, firm, and corrugated. Microscopically they were found to consist mainly of fibrous tissue with much cyst formation. Since the operation the patient had gradually been filling up again and had had to be again tapped. There was no history of alcoholism.

ENORMOUSLY DILATED FALLOPIAN TUBE WITH OVARIAN CYST.

Dr. Horrocks showed a specimen, taken from a healthy-looking woman, æt. 38. It consisted of an enormously dilated Fallopian tube, which lay right across the lower part of the ovarian cyst, and looked exactly like a piece of small intestine. The broad ligament lay over the tumour, and prior to operation the diagnosis was obscure. It turned out to be a case of ovarian cyst, and the corresponding tube was dilated to such an extent that one could introduce two fingers into it. It contained, when fresh, a fluid similar to that in the ovarian cyst. It maintained its exaggerated calibre right up to the uterus, so after applying a ligature as close to the uterine extremity as possible, he dissected out some of the swollen mucous membrane and applied tincture of iodine. He did not pass a probe into the uterus, so that he was not in a position to say whether or not the uterine passage was obliterated, as the other aperture appeared to be. There had been amenorrhœa for the last six months, but previously the patient had always suffered from menorrhagia or metrorrhagia. There was no torsion of the pedicle, which was as wide as the broad ligament itself.

Dr. Braxton Hicks on a case of

INTERMITTENT CONTRACTIONS OF UTERINE MYOMATA AND IN PREGNANCY IN RELATION TO DIAGNOSIS.

which will be found under "Original Communications."

Dr. Horrocks, commenting on the statement by an eminent abdominal surgeon that the occurrence of intermittent contractions of the uterus during pregnancy was doubtful, and that if they did exist their diagnostic value was probably very small, said it was open to anyone who would carefully examine the uterus to ascertain for himself that the author's observations on this point were observations of fact. He himself had demonstrated these contractions and relaxations to a whole class of students, and they could be made out as early as the end of the fourth month. This was only what he would have inferred from some researches which he had carried out on unstriped muscle fibres. Years ago when he found that they underwent alternate contraction and relaxation throughout life. It must under any circumstances be much more difficult to make out alterations in shape in fibroid myomata, and when this alteration did occur, it was very different from, and less than, similar contractions in the pregnant uterus. Owing to the contents of the uterus being fluid when it contracted, it tended to assume a spherical shape, whereas a fibroid tumour would not alter its shape nearly as much. Although he had examined a large number of fibroid tumours with this object in view, he had never been able to satisfy himself that any perceptible contraction took place. He asked the author whether he had noticed any periodicity in the contractions, and at what interval they occurred?

Dr. Hicks said the contraction was noticed two or three times during the *séance*.

Dr. Cullingworth observed that, though contractions did occasionally take place in soft uterine fibromata, this sign, considering the large number of these cases that came under their observation, was found in a very small proportion of them. This might of course be due to the fact that it had not been looked for, but though he had looked for it a number of times, he had never been able to satisfy himself that it actually took place, in spite of the fact that it is very easy to be deceived when looking out for any particular phenomenon. In reference to the author's observation that this sign would enable them to distinguish between an intra-uterine pregnancy and the sac of an extra-uterine pregnancy, he complained that no details had been given as to how this was done. He recalled a case of extra-uterine gestation in which abdominal section was performed eight months after the death of the fœtus. The uterus in that patient could be seen and felt undergoing rhythmical contractions, and it bulged forward, the abdominal wall rendering it distinctly salient above the pubes. The empty uterus lay in front of the gestation sac.

Dr. Fenton thought it would be conceded that this diagnostic sign was difficult to obtain in most cases of pregnancy. Their President, years ago, when he had the honour of being his house physician, used to impress upon them the importance of this sign, and they used to watch for it very carefully, except, however, in women with thin abdominal walls or in whom the movements of the fœtus were unusually brisk, no contractions could be made out which could by any stretch of imagination be called rhythmical, nor, indeed, any at all visible to the eye or hand, except on manipulation of the uterus. He was consequently somewhat sceptical as to the practical value of this particular sign.

The President pointed out that with an abdominal tumour which exhibited alternations of hardness and softening the chances are vastly in favour of its being uterine. He denied ever having taught that there were contractions that could not be *seen*, though they could be felt. The cases in which he had found this sign most useful were precisely those in which there was most difficulty in distinguishing between the pregnant uterus and a soft fibroma projecting into the uterus. It might be, as suggested by Dr. Fenton, that the contractions occurred in consequence of manipulations of the uterus, but if so, very little manipulation would suffice to elicit them. At the same time they could not fairly be described as rhythmical. Dr. Cullingworth had alluded to the difficulty of distinguishing these functions, but there was another sign which facilitated their so doing, viz., the alternate loudness and softness of the uterine souffle. This was loud when the contraction was coming on, becoming comparatively soft as relaxation took place.

Dr. Hayes suggested that the readiness with which the contractions could be felt depended not only on the thinness of the abdominal walls, but also upon the condition of the muscular system of the particular patient.

Dr. Braxton Hicks, in reply to Dr. Horrocks' question whether the author had observed the contractions in the fibroid in the case he mentioned, said that he had noticed them more than once in each examination. He also said, in answer to Dr. Cullingworth, that in the case of our detecting a living fœtus, he could not say whether it were intra- or extra-uterine, with regard to the doubt some may have as to the practical value of the knowledge of these uterine contractions, he had, in the many papers he had written, described cases illustrating the many advantages; but he might instance the case of suspected pregnancy where there was amenorrhœa. One could place the hand over the lower abdomen without raising the suggestion of pregnancy and finding a tumour above pubes corresponding to the date of amenorrhœa. Central, hard, and firm at the first, and then becoming soft, almost to be felt whilst handling it, and then, after a little time, hard again, one could satisfy oneself that it was pregnancy, sufficiently so to urge further examination. Where there is a uterine fibroid with pregnancy, it is not difficult to make out when the uterus contracts that the irregular and doubtful mass is one. Also in cases of twins, after the sixth month, the uterus is often of so irregular a shape that there seems to be two tumours, but when the uterus contracts the irregularity disappears, and it assumes the globular shape, and the apparent two are shown to be but one. The author further added in his first paper that he had no information whether it was possible for the distended bladder to simulate the pregnant uterus in regard to these contractions. He had no such information now, but he thought it important that observations should be made on this point when opportunities served.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of Obstetrics.

Meeting held Friday, April 13th.

The President, Dr. Richard D. Purefoy, in the Chair.

OVARY AND TUBE REMOVED FOR RECURRENT SALPINGITIS.

Dr. Alfred Smith showed a tube and ovary which he removed from a married woman, æt. 29, on March 21st, 1894, who suffered from a severe pain on the right side, of a burning, dragging character, referred to a point two fingers in width below and to the right of the umbilicus; this pain was constant and at times became very much worse, especially before and during the menstrual periods. There were extensive adhesions of the omentum to the abdominal wall, and evidence of general adhesive peritonitis. The ovary and tube were removed after considerable difficulty. Peritoneal bands, which were constricting the Fallopian tube on the left side, were broken down. The vermiform appendix, which was adherent, and fixed by peritoneal adhesions, was released. Recovery perfectly afebrile and uneventful. April 8th.—Changes came on; old pain disappeared. April 11th.—Changes completely over, and leaves hospital cured.

MYOMATOUS UTERI AND OVARIES, AND APPENDAGES, REMOVED FOR RECURRENT PERITONITIS.

Dr. W. J. Smyly showed—1. A large myomatous uterus, which he had removed by abdominal section. The operation was exceedingly difficult owing to two of the largest tumours having to be enucleated from the cellular tissue. One of these almost filled the true pelvis and caused so much distress by pressure as to necessitate the operation. The vagina was so compressed and distorted as to render its disinfection very difficult, and her death from peritonitis on the third day was probably due to this. 2. The second uterus, which was about as large as a cocoanut, and reached to within an inch of the umbilicus, was the first case in which he had removed a large myomatous uterus per vaginam by morcellement. He was, however, very favourably impressed, especially by the comparative absence of shock. 3. Ovaries and appendages removed for recurrent attacks of peritonitis. Upon opening the tubes after removal he was surprised to find them distended with blood.

Dr. M'Ardle thought that possibly Dr. Smyly's patient had died of thrombosis of the pelvic veins, causing emboli in the lungs. He had seen two similar cases, in which death occurred suddenly, and in which he discovered this to be the cause.

Dr. Smyly said that a *post-mortem* examination of the patient had been made, and that acute peritonitis had been found.

Dr. A. J. Smith said that double hæmatosalpinx was usually associated with double obstruction high up in the canal. Hæmatosalpinx is usually the outcome of tubal gestation.

ANENCEPHALIC MONSTER.

Dr. F. W. Kidd exhibited an anencephalic monster. There were some points of interest. The mother of this monster was only fifteen years and ten months old when it was born. She was only seven and a half months pregnant. She had had an *ante-partum* mammary abscess a month previously, which was opened and dressed at the Coombe Hospital. The monster presented by the face, the general rule in these cases being breech or transverse; it just breathed after birth. There was only one nostril, There was spina bifida of cervical and upper dorsal vertebræ and double talipes. At the same time as the patient had the mammary abscess she had collections of pus at the base of two finger nails. The same breast suppurated after delivery.

Dr. Smyly thought that there might be some connection between the pus under the patient's finger nails and the *ante-partem* mammary abscess.

Dr. Tweedy said that during the past year he had seen two similar cases. In one of the women a small sinus still existed when she was delivered, and perhaps she might have infected herself from it, for she had an attack of puerperal fever. He thought that parturient women should, if possible, have no open sores.

Dr. Thompson mentioned another case of *ante-partem* mammary abscess.

RUPTURED TUBAL PREGNANCY.

Dr. Alfred Smith read a paper on Ruptured Tubal Pregnancy, successfully treated by Abdominal Section. He could only find a record of two previous successful operations in Ireland—one by Dr. Smyly and the other by Professor Byers, Belfast. On March 22nd of this year he was asked to see a married woman whose changes had been regular up to February, when a menstrual period commenced which lasted up to March 23rd, without any unusual pain. She sought his advice because a dose of salts, taken in the early morning, had not acted, and that for the past hour or so before his arrival she complained of severe griping pains in the abdomen, and a feeling as if there was some lump in the back passage which caused a constant desire to stool, but without any result. A diagnosis of ruptured tubal pregnancy, with intra-peritoneal hæmorrhage, was made. As the great collapse pointed to no other conclusion, nothing very positive could be made out by the bi-manual method of examination. The abdomen was opened, and the left Fallopian tube, which was ruptured in its outer third, was removed. No trace of ovum could be found, although a careful search was made in the large quantity of blood clots which filled the pelvis. The specimen was shown. The peritoneum was douched with saline solution and a drainage tube inserted. The recovery, which was perfect, was interrupted by an attack of pneumonia on the second day after operation. An interesting query—Is this case an example of complete tubal abortion in ectopic gestation? The after treatment varied much from the routine method, as the patient received a generous dietary on the second day after operation without any inconvenience following. The case illustrates the value of—1st. Trendelenberg's table. 2nd. The use of saline solutions for peritoneal douche and enema in cases of severe hæmorrhages. And lastly. That our after-treatment in abdominal section can be guided by rational methods, and that it is not necessary to follow slavishly the old starvation process.

Dr. More Madden having congratulated Dr. Smith, said that it was a most interesting feature in the case that no fœtus could be found. The embryo usually escapes into the peritoneal cavity and perishes. Cases of tubal pregnancy are more frequent than is usually supposed.

Dr. Smyly said that success in these cases depends upon decision. The most difficult part of the operation is to decide to open the abdomen. When you are called to see a lady who, a few hours previously, was in perfect health, and who was seized with a fainting fit, you naturally hesitate to operate, hoping that, as sometimes happens, she may get all right, and then, perhaps, when she gets another fainting fit you imagine that the time for operation is past. He was astonished at the number of tubal pregnancies he had seen when in Berlin. An assistant in one of the hospitals told him that they got one on an average every fortnight. He thought Dr. Smith's case to be a typical one of "tubal abortion."

Dr. E. H. Tweedy said that he thought that flushing out the abdomen with hot water added to and never lessened the shock attending abdominal operations.

Dr. M'Ardle said that it was well before inverting the patient to remove as much blood clot as possible from the pelvis and abdomen.

Dr. Bate asked Dr. Smith did he think there was any connection between the tubercular disease of her lungs and the ruptured tube.

Dr. Smith, in reply to Dr. Bate, said he really could not tell. He said it was a curious fact, and perhaps it was only a coincidence, that all the patients suffering from tubal pregnancies of whom he had any record had been curetted some six or eight months previously. In this operation he had not used *hot* water, but saline solution of the temperature of the body. A marked improvement in the circulation followed its use.

The Section then adjourned.

THE HUNTERIAN SOCIETY.

Meeting held April 25th.

The President, Mr. C. J. Symonds, F.R.C.S., in the Chair.

DISCUSSION ON DIPHTHERIA.

Dr. Newton Pitt—In defining what we mean by diphtheria it is not sufficient to describe it as a disease characterised by manifestations in the throat, nor even as a throat affection associated with the formation of membranes, for such membranes may be due to traumatism or to the presence of staphylococci and streptococci, especially in presence of scarlet fever and measles. It may be, perhaps, defined to be an epidemic infective membranous form of sore throat often associated with nephritic changes and followed by the development of peripheral neuritis. Now the "sore throat" may take the form of mere injection of the mucous surfaces, or there may be tonsillitis or membranes to be seen. The question is, Are the milder forms of sore throat ever followed by the characteristic neuritis? The question as to whether the slighter forms of sore throat which often prevail during outbreaks of diphtheria only precede, or are themselves diphtheritic, must for the present remain open. The view that many of these slighter forms of sore throat are really due to the action of a specific bacillus is steadily gaining ground. Many membranous throats, however, only yield cultures of streptococci or staphylococci, while others, in the absence of any membranous formations, show the bacillus. This uncertainty as to what constitutes diphtheria explains how it is that so many outbreaks escape repression, and it also leads to confusion in the nomenclature. Thorne Thorne has pointed out the tendency of diphtheria to prevail in association with certain meteorological conditions although it is pretty generally conceded that unsanitary conditions *per se* are not sufficient to produce diphtheria any more than typhoid fever or cholera. Unsanitary conditions, however, are probably only a means of favouring the propagation of the disease.

Dr. Goodall.—Diphtheria may be defined as an inflammatory disease primarily of the tonsils or fauces attended by the formation of some sort of deposit, and frequently, though not necessarily, associated with the formation of a special membrane due to the development of a micro-organism associated with certain secondary effects due to the absorption of toxines. Membranes are thus not made an essential feature. As a matter of fact I believe it may be unaccompanied by any deposit whatever, for I have repeatedly met with cases in which the usual secondary effects were observed without any trace of exudation. There may thus be diphtheria with, and diphtheria without membranes. We have to ask ourselves whether there is a non-specific membranous laryngitis and a non-specific membranous inflammation of the fauces. I can only say that I have never come across a case in which the so-called diphtheritic paralysis followed in which the fauces were not previously affected. For practical purposes I am disposed to accept as diphtheria all cases of membranous sore throat in the absence of some other cause, such as scarlet fever. If there be any local spread, the disease is almost certainly diphtheria, and if it involves the larynx, then it is certainly diphtheria. Diphtheria sometimes seems to occur as a complication of other acute diseases. The two specific fevers with which I have seen it most associated have been scarlet fever and measles, though I have met it in association with whooping-cough, and once with typhoid fever. On only three occasions have I seen it in association with small pox. Of course, any one acute disease may complicate any other, but when this is the case the origin of the second disease can usually be traced to a definite source. No one of these diseases predisposes to any other, and the occurrence of one of them as a complication is quite accidental. Diphtheria differs, however, in two respects: viz., its occurrence in association with scarlet fever and measles is too frequent to be merely accidental; and it is often quite impossible to discover any history of possible communication. Scarlet fever is a disease for which diphtheria seems to have a special liking, and there is a certain similarity between the early symptoms of both of them. They are prevalent together, and are sometimes so intimately connected as to give rise to the belief that they are one and the same disease. The tendency of diphtheria to complicate convalescence from scarlet fever is well known. I have over and over again seen patients brought from the same house, some with scarlet fever and some with diphtheria. It is absolutely necessary to distinguish between diphtheria and a diphtheritic sore throat, for the use of the latter term tends to confuse the points at issue. We often see a tough thick membrane in scarlet fever, and it remains to be seen whether its occurrence is a mere coincidence. This is a very important point, because, if this membrane be diphtheritic, it is obviously dangerous to place children suffering from simple scarlet fever in the same ward as those who have the disease associated with this particular form of sore throat. Personally I am inclined to view this complication in scarlet fever as a consequence of a very severe angina. First, the larynx is very rarely involved in this form. Out of 68 cases of fever with diphtheritic fauces, in only 3 per cent. was the larynx affected, whereas in 1,071 cases of primary diphtheria, croup was observed in 204 cases. Only 3 of the 68 cases developed paralytic symptoms, whereas 125 of the other series did so. Again, the membrane which forms in the course of an attack of scarlet fever does not recur when once it has disappeared. Lastly, those cases of scarlet fever with a diphtheritic throat do not give rise to other cases of diphtheria in the ward. When undoubted diphtheria does occur in scarlet fever patients it is much more fatal than primary diphtheria. I have had ten cases of patients admitted suffering from diphtheria bearing evidence of a recent attack of scarlet fever. It would be interesting to know whether this is frequently observed in private practice. Though I have alluded to the fact that diphtheria occurs as a complication of measles I have never seen it supervene in association with rotheln or German measles. When diphtheria does occur in association with measles it is more fatal than when it complicates scarlet fever. Out of 15 cases of measles thus complicated 14 died. The membrane usually appears much earlier than in scarlet fever, very often while the rash is still out, and the larynx was affected in 14 out of 15 cases. Cases of uncomplicated measles may give rise to cases complicated with diphtheria. Of 1,064 patients with scarlet fever 27 got post-scarlatinal diphtheria—1·5 per cent. Sweeting on a series of 11,000 cases gives 3·3 per cent., whereas out of 128 cases of measles 15 were complicated with diphtheria, and 11·7 per cent. Among my own cases, 41 patients with primary measles, 6 were complicated with diphtheria. The frequency with which diphtheria occurs as a complication during convalescence from scarlet fever is said to be because this is a disease accompanied by throat inflammation predisposing thereto, but this plausible explanation is not borne out by facts. It is rare in diphtheria to get a history of a previous attack of sore throat. If the scarlet fever throat predisposed thereto diphtheria would be more frequent in this association than it is. Moreover, it is remarkable how little diphtheria tends to spread when these cases occur in scarlet fever wards. Again, of all the patients sent to our hospitals as suffering from diphtheria who only had tonsillitis, only two contracted diphtheria. It is evident, therefore, that other conditions must be present for a patient to contract diphtheritis besides an unhealthy state of the fauces.

Dr. **Sidney Martin**.—Very little is known about the membranous forms of sore throat other than diphtheria. Much confusion has been caused by the use of the term diphtheritic inflammation, which Virchow defined as "an inflammatory process characterised by an exudation of fibrin and by necrosis of the tissues." There are various causes of this form of inflammation, one of which is diphtheria. It would be best for us to discard this term and to speak of membranous or fibrinous inflammation, just as we speak of purulent or sero-purulent. The marked enlargement of the spleen which is observed in septic sore throats may, perhaps, enable us to distinguish between these cases and true diphtheria. At present we are compelled to rely for our diagnosis upon cultivations of the secretions. Diphtheria may, of course, occur in two forms, viz., mild and severe. We certainly meet with cases in which paralytic symptoms follow very slight attacks of sore throat which have never been suspected to be diphtheria. Then, too, the membranes may be extremely thin, so much so as only to be visible on making sections of the affected mucous surfaces. As I have shown elsewhere, the membrane is the fount and origin of the disease, a thesis which I think cannot at present be seriously gainsaid. Diphtheria may be defined as a disease of insidious onset (though it does sometimes begin suddenly) which may or may not be associated with membranous formations in the throat and accompanied by fever and bodily depression, with or without the presence of albumen in the urine. The tendency of the disease is to produce a cardiac affection showing itself by fatal syncope or tachycardia, or by palsy due to nerve degeneration, sometimes small in extent, sometimes widespread. It is characterised also by a tendency to invade the larynx by specific bacilli which cause a fibrinous exudation. This bacillus breeds in the false membranes and produces poisons, transforming the proteids of the spleen into products which give origin to the symptoms of the disease. In the case of a man who lived twenty-nine days and died after developing paralysis of the palate on the ninth day, with loss of knee-jerk between the twelfth and fourteenth day, and followed by general paralysis, sections of the spinal cord showed an increase of augmentation in the cells of the motor area of the cord and degeneration of the nerves leading to them. Rupture of the axis cylinder is a preliminary step to degeneration of the nerves towards the muscle. Ultimately only the primitive sheath remains, with masses of black here and there, which constitute the remains of the substance of Schwann. There is also an increase in the number of nuclei. In all cases of acute diphtheria which last more than ten days and die it is possible to make out this nerve degeneration. The lesions resemble the fatty degeneration which follows the experimental injection of the poisons from diphtheritic secretions.

Dr. **George Turner**.—Recent observations tend to confirm the view that diphtheria and drain defects are connected, if at all, only casually, but public opinion, like a pendulum, after swinging too far in one direction, is very apt to swing back again equally far in the other. Because sanitary defects do not appear to be directly responsible for outbreaks it would be unwise to assume that they are absolutely without importance. Bad smells, &c., certainly conduce to a prevalence of sore-throat, and I hold that throats thus affected are more susceptible to the poison. It is astonishing what a large proportion of patients suffering from diphtheria give a history of cold prior to the attack of diphtheria, and this I think is because one of the commonest manifestations of "cold" is a sore throat. In older accounts of diphtheria the membrane is said to have frequently spread round the margin of the teeth with the gums, and if this is no longer observed it may be by reason of the more general use of the tooth brush. I believe, too, that the symptoms are very much exaggerated if the patient happens to be living under bad sanitary circumstances. The disease certainly hangs about particular localities, and I can point out places in my district which are never free from diphtheria for twelve months together. Such places are usually very damp and very dirty. One often hears of families having scarlet fever and diphtheria either separately or in combination. I am not prepared to say that they cannot exist simultaneously, but I have no doubt that a mistaken diagnosis is responsible for 99 per cent. of the cases certified as scarlet fever and diphtheria. Persons whose families suffer from scarlet fever and who nurse them often suffer from sore throat, but these people do not spread diphtheria, while they do certainly spread scarlet fever. Patients who have had diphtheria without scarlet fever will generally be found to desquamate, and these diphtheria patients spread a disease which is scarlet fever.

Moreover, they do not as a rule suffer from diphtheria paralysis. In 1889 and 1890 scarlet fever was very prevalent in Bishops Stourton. There was only 1 per cent. of fatal cases, and it was imported thence into a small neighbouring village. In the following January between the 9th and the 23rd five cases of scarlet fever occurred and were removed to the hospital. Nothing more was heard of the disease until April, when a girl was sent in with diphtheria and died on the fifth day. Her mother, who had accompanied her to the hospital and had then returned home, was taken ill and was also said to be suffering from diphtheria. On the same day in another house a boy, æt. 9, was sent to the hospital, also certified to be suffering from diphtheria. In hospital, however, the diagnosis was changed into one of scarlet fever. I found three other children in three other houses suffering from scarlet fever. All the seven people I had discovered to be ill had obtained their milk from one particular farmhouse, and when I went to the farm I saw the farmer sitting by the fire with his throat wrapped up, the room looking straight into the dairy. Two of his children had been ill on March 19 and 29 and were then desquamating. The farmer was soon after sent in for diphtheria, but after awhile he was found to be suffering from scarlet fever. All the other 25 cases were unmistakable scarlet fever. The woman remained in the hospital for 24 days, and she had not been out of the hospital a week before she began to suffer from paralytic symptoms. That would doubtless be reported as a mixed epidemic, but all the cases had been consuming milk exposed to scarlet fever contamination. The woman had probably caught her diphtheria from the hospital, and not from her child. Bad surroundings intensify the ordinary scarlatinal sore throat, and when the throat symptoms predominate the true nature of the disease is not recognised. Most cases of diphtheria are mild, and there is hardly any form of sore throat which may not turn out to be diphtheria. Thus one sees in the hospital a marked case of diphtheria produce in another patient a slight sore throat, so trivial that it hardly attracts attention, and this mild case, taken to a distant village, sets up an outbreak of well-marked diphtheria, though you might not be able to recognise it. Those sore throats often commence the epidemic. If you make inquiry you will find that the first deaths are attributed to croup until a clear case of diphtheria is identified, and thenceforth all the cases are described as diphtheria. These patients with slight sore throat often do very little harm while they live at home, but if they are admitted to a school which has been reopened, the epidemic is started afresh. Children going to elementary schools are very apt to get wet feet or be otherwise exposed, and so get a condition of the throat which renders them very susceptible. It is to be hoped that we shall soon have some ready means of distinguishing one form of sore throat from another. Cultivation experiments are obviously out of the question in general practice. I suppose it is generally admitted at present that cows suffer from a disease which may communicate diphtheria. I have seen a form of sore throat among pigs which closely resembles the form of sore throat met with in human beings. Although I know that it is against the weight of skilled opinion that the disease can be spread from fowls to human beings, I know personally that fowls do suffer from a form of throat affection which is followed by paralysis, and that this disease in fowls often follows or precedes diphtheria among human beings. An old farmer woman of my acquaintance who was attending to her fowls thus affected, herself contracted diphtheria and spread it to her children, yet so far as I am aware there had been no case of diphtheria for many miles around.

Discussion adjourned.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.

Meeting held Tuesday, May 1st, 1894.

Mr. John Appleyard, F.R.C.S., President, in the Chair.

Case of Pseudohypertrophic Muscular Paralysis.—Mr. Hughes showed a child, æt. 7. During the past eighteen months his gait had altered, and the muscles became weak, the pupils were widely dilated, knee jerks gone, mental condition somewhat impaired, and loss of memory noted. The infraspinati were possibly somewhat thickened, and it was probably an atypical case of pseudo-hypertrophic muscular paralysis.

The Intralaryngeal Operation.—Dr. Sam Lodge showed specimens and preparations from growths removed by intralanyngeal operation. In two cases papillomata giving rise to dyspnœa after seventeen and twenty-five years respectively, and the other a mixed-celled sarcoma of rapid growth.

Case of Mastoid Disease.—Dr. Adolph Bronner showed three cases of mastoid disease and operation in adults, there was a history in each case of discharge from the ear, followed by intense pain in the mastoid region, in two cases there was no visible swelling over the mastoid process, in one case only slight swelling; in none was there any marked rise of temperature, and in all the periosteum and external layers of bone were apparently healthy. It was only after chiselling to the depth of six or ten millimetres that pus or granulation tissue was found. The cases were of great practical importance, and showed how extensive disease might be present in the mastoid process with no external swelling or sense of pain on pressure. Whenever pain was present we should not be content with Wilde's incision, but cut down on the mastoid antrum or cells, where in most cases extensive disease would be found.

Severe Case of Tetany.—Mr. Hebblethwaite read notes of a severe case of tetany beginning with pains, tingling and sensation of breaking in the muscles of the arms, then flexion of the thumbs across the hands and movements which persisted even during sleep in a stout woman, æt. 46, after a sharp attack of diarrhœa in the eighth month of her sixth pregnancy, and after nursing a child with typhoid fever. The attacks were worst some hours after an easy labour, violent general spasms of trunk and legs, and even of the muscles of deglutition and speech; very painful, and without any loss of consciousness. Chloral and bromide were used freely; the urine was normal. In the following pregnancy about the seventh month she had occasional attacks, which were kept under by sedatives. during labour these attacks gave rise to fear of dyspnœa.

Pitfalls in the Diagnosis of Pneumonia.—Dr. Major read a paper on pitfalls in the diagnosis of pneumonia; variations in the localisation of the early pain suggesting peritonitis, typhlitis, or even lumbar pain, with fever and small-pox. Violent early delirium, which, if fever cannot be made out, is indistinguishable from acute mania. The Skodaic percussion note may cause trouble; or "silent" pneumonia, unless we note that the heart apex is not displaced. Large consonating *râles* may occur during resolution, and in a thin or wasted patient might lead to the unfortunate diagnosis of advanced phthisis.

Mr. Barber showed a case for diagnosis, a young girl with a copious purpuric rash.

Dr. Adolph Bronner demonstrated a modified Javal's ophthalmometer for the direct estimation of corneal astigmatism.

Paris, May 5th.

Strangulated Hernia.

At the meeting of the Société Chirurgicale M. Ségond spoke on the choice to be made between an artificial anus and resection of the intestine with subsequent suture in the treatment of gangrene of the gut following strangulated hernia. For him, he having tried both operations, he preferred establishing at first the artificial outlet, and when the patient has sufficiently recovered from the shock and the prostration produced by the affection, he endeavoured to improve the position of the man by resection and suture, and so relieve him from a very disagreeable infirmity.

M. Terrie said that he entirely agreed with M. Ségond, as resection of the intestine was always a very grave and tedious operation. Yet he could not forget the results obtained by M. Murphy with his new method of entero-anastomosis, which succeeded in seven out of eight operations. Further, the operation is very simple as it only lasts about fifteen minutes. M. Terrier thought it would be well to try this method, for if it succeeded, as reported by Murphy, the treatment of strangulated hernia would be singularly modified.

Electrocution.

M. D'Arsonval related the case of a railway porter who was rendered senseless by an electric current of 5,000 volts. Although the man was apparently dead for forty-five minutes before help could be brought to him, he was recalled to life by artificial respiration and traction of the tongue as recommended by Laborde.

M. Laborde said that artificial respiration alone would not have sufficed in such a case, and cited the history of two men who were recently knocked down by an electric current of 2,000 volts near Geneva; one was treated exclusively by artificial respiration, the other by traction of the tongue. Only this latter recovered.

Treatment of Hydrocele.

The classical treatment of hydrocele, puncture and injection of tincture of iodine or some other irritating liquid, has been rendered much more simple by a *confrére* who has published the result of several cases cured rapidly by his method. He inserts the trocar into the most dependent part of the tumour and removes the liquid; he then injects a five per cent. solution of phenic acid which is removed almost immediately. The trocar is introduced a second time into the canula, and pushing it up towards the highest point a counter opening is made. The trocar is again withdrawn, and a drainage tube is passed through the canula and left in position, the canula being removed. The patient can immediately get up and walk about. The drain is withdrawn on the fourth day, and in a week the man is cured.

Favus Tonsurans.

The following treatment has been considered very efficacious in favus. The hair is cut close around the spots and the parts washed with ordinary soft soap, after which the compress hereunder is applied three times a day:—

Thymol, ʒss;
Chloroform, ʒv;
Olive oil, ℥iij.

As soon as the crusts covering the patches become detached the parts should be carefully epilated, and, finally, a solution of two parts of tincture of iodine and one of glycerine should be painted once a day over the denuded spots. The treatment lasts about a month or six weeks.

Ice to the Heart.

Dr. Jullien, of Saint-Lazare, has published an article on the advantages of applications of ice to the heart, increasing its tone and vigour. Called to a young girl who was suffering from typhoid fever, he treated her by the Brand method, but to little purpose, as the cold bathing did not have much effect on the temperature. The patient grew rapidly worse, the pulse beat was 160, and the temperature stood at 103°; death was imminent. At this point the idea came to him to apply a bag of ice to the heart. Fifteen minutes afterwards the number of pulsations diminished and their strength increased; if the ice were removed the alarming symptoms returned. Consequently, the ice was continued for several days, and the patient made a good recovery.

In another case the same treatment produced a like satisfactory result.

Germany.

[From our own Correspondent.]

Berlin, May 4th.

Malakine.

Another antipyretic, to which the name of malakine has been given (μαλακός, soft) on account of its gentle action has been just introduced by the Chemical Industry Society of Basle. It is a salicyl derivation of paraphenetidine, and, therefore, nearly allied to phenacetine. It is met with in the form of small clear yellow acicular crystals, with a melting point of 92°C., is insoluble in water, scarcely soluble in cold alcohol, but readily in hot. Soluble in caustic soda forming a soda salt, weak mineral acids separate it into salicyl-aldehyde and p. phenetidine. After experiments had shown that it was harmless on animals, it was tried in cases of infective fevers, acute rheumatism, and neuralgias, and the result was ascertained to be that the drug is an agreeable and safe remedy in acute rheumatism, that it possesses the great advantage of being free of bye effects, and deserving of use in place of other salicyl preparations in delicate people. As an antipyretic, malakine acts slowly and gently without any disquieting symptoms; it acts well in weak people with debilitated circulations. It may be given for long periods without harm to the digestion in neuralgias, habitual headaches, &c. It is best given in wafer, and from two to four grammes may be given daily.

Dr. Oscar von Bauer, who had tried it in Prof. Drasche's wards, agrees on the whole with what has been already stated as to its mild and gentle action, and also as to its efficacy in acute rheumatism and as an antipyretic.

Quinine and Methylene Blue in Malaria.

Dr. H. Rosin has been making investigations into this subject in Prof. Senator's wards, and reports his results in the last number of the *Deustche Med. Wochensch.* The principal object of the research was to determine under the microscope the influence of these agents on the living malaria parasites, the plasmodia, and to compare the effects observed with clinical results. Calculating that quinine in the doses ordinarily given in ague reaches the blood in a dilution of about 1 in 5,000, a solution of this strength was applied to the living plasmodia. Contrary to expection, the movements continued as heretofore, and were observed even after the lapse of ten hours.

After this a solution of methylene blue was next tried in a strength of 1 in 20,000 of neutral saline fluid. Immediately this solution was applied, the movements of almost all the plasmodia ceased at once, and the nuclei became completely motionless, and *simultaneously* the parasites began to take on a blue colour, so that after a few minutes they were quite blue, whilst the nuclei of the leucocytes were completely free from change. After the lapse of half an hour, the nuclei of the white blood corpuscles were stained, the red blood corpuscles retained their colour, form, and shape. The movements that ceased from the methylene blue did not return. In the physiological saline solution, the red blood corpuscles were preserved several days, and also the leucocytes with their blue coloured nuclei. The author recommends the methylene blue saline solution as an excellent staining agent for the plasmodia, provided the solution is added to the fresh blood preparation in which the parasites are still living. He thinks the living parasites have a greater affinity for the colour than dead ones. He believes the relation between the reagent and the parasite is rather a vital than a chemical one.

The Twenty-Third Surgical Congress.

This Congress was commenced on April 20th, (for the first time holding its meeting in the Langenbech House) under the presidency of Prof. von Esmarch. The meeting, which usually takes place in Easter week, having been postponed on account of the International Congress at Rome. At the opening meeting the President alluded in fitting terms to the lamented death of Theodor Billroth, "in whom the German society had lost a founder, an honorary member, a leader, and a master." The scientific work was begun by an address by Prof. Bruns, of Tübingen, on "the Results of Tuberculous Joint Inflammations under Conservative Treatment." This paper is perhaps the most important submitted to the Congress. I hope to refer to it later. The next paper was by Dr. Hoffa, of Würzburg, on "the Pathologic Anatomical Condition after Operation for Congenital Dislocation of the Hip," showing by a preparation how new cartilage is really formed in the socket. He then proposed a new method of operating for resection at the hip-joint, pointing out that the bloodless treatment of coxitis was practicable where the ligamentum teres was absent, but impracticable when present.

Fœtal Circulation.

At the last meeting of the Gesellschaft Strassmann next read a paper on the closure of the ductus arteriosis, prefacing his remarks with the various theories advanced by different authors, such as thrombi, which he considered a rare occurrence; another critic placed it to the credit of the contracting vessels. The changes that have taken place in the ductus cannot clearly be proved by anatomy. Histological changes point to alteration fn the walls of the vessel, but is not conclusive proof of the closure. He considered that we must look for a mechanical agency in its closure or an alteration of pressure in the aorta. He is inclined to favour the mechanical by the easy opening into the aorta. Zunz after many sections on sheep concluded that the opening was closed by a sort of valvular or roof covering. Strassmann has also observed this plate covering in the ostium, but there are certain conditions that must be present to accomplish the closure. The breathing must commence when the blood pressure is immediately reduced on both sides of the heart as well as the aorta; on the subsequent rise of pressure the duct has been closed and if an equilibrium exist the separation is complete. By injections with coaguable fluids Strassmann has accomplished this theory by experiment. If the fœtus be not fully developed the lamella may not be in a condition to close the opening which is found experimentally by the same fluid. This theory would justify blood-letting by the cord, which would probably carry the child off by failure of the heart. Virchow divides these cases into primary and secondary, the latter those which have closed and again reopened. The former he considers due to atelectasis in breathing, abnormal pressure in the heart, stenosis, pulmonary artery, or undeveloped ductus arteria. Strassmann is of opinion the mechanical is brought out in the opening of the lumen in advanced years without disturbing the circulation. Rokitanski observed such a lamella in aneurysms and stenosis, which arose from the morbid changes. Again, the clinical proof is in favour of the mechanical closure from the momentary cessation of the flow in the duct. The sounds of the heart in the newborn are as clear as the fœtus. There is no blowing sound in the fœtus because both streams are moving in the same direction, but if the duct remain open after birth a systolic murmur is heard from the rushing of the blood from the right side into the left. Senator said the communication was interesting, but he could not clearly see how the inspiration reduced the pressure in the pulmonary artery, while it rose in the aorta. He also maintained that no murmur was present when the two currents were of equal pressure and moving in the same direction, but if unequal a murmur would be found. Strassmann said that the pressure was reduced in the aorta by the inspiration, and that both symptoms were reduced at first.

◆

Austria.

[FROM OUR OWN CORRESPONDENT.]

Vienna, May 4th.

Traumatic Epilepsy.

After Dr. Clùr had demonstrated his new sphere for illuminating cavities, Weiss showed a case of Prof. Benedikt's to the Gesellschaft with a strange history of epileptoid attacks. The patient, æt. 40, was a printer by trade, and was received into ward on the 7th March, complaining of pain over the occiput, with a feeling in the head of being "stuffed or padded" in addition to this feebleness of the legs. The examination of the part in movement of the neck was normal, except a slight increase of the tendon reflex, which might be observed on some occasions. His mental condition seemed to be normal, and otherwise he had nothing to complain of.

The history dates as far back as 1869-70, when he had several attacks of lead colic but recovering from this, remained perfectly healthy up till 1874, when he got his right leg broken, which healed up within three months, yet in 1875 we find him still moving on crutches, being unable to walk, and the foot greatly turned in.

Again he received an accident on the injured leg, was confined to bed, but it healed up within eight days. In 1881, he received an injury to the chest while manœuvring which produced hæmoptysis, and caused him to remain in bed sixteen days. About this time, he had a fit, the first recorded in his history. In 1882 he had another attack, which left him paralysed on one side for eight days after the attack, and disappeared with baths. In 1893, his father died, and again the fits supervened, continuing more or less since that date on the slightest emotion or severe effort.

The first fit is described with spasm, difficulty of breathing, stiffness of the right arm, and sudden cessation of right leg, with cramp on effort, accompanied with paralysis agitans. Sometimes this contractile movement was jactitatory, and could be transposed to the left side by holding the right leg. In severe attacks, "trismus" was present, with a pendulum movement of the head; the mind throughout was never clouded. After each attack, there was an excited sexual desire, accompanied with the emission of great quantities of urine, which was often cloudy. A few drops of amyl-nitrite were tried in the fits, but without the slightest result; pushing this on a subsequent occasion transposed the jactitations to the left side, but did not modify the attack; trismus was still present, *i.e.*, a tetanic cramp in the region of the nervous trigeminus. Galvanising sympathetic of the neck rapidly induced these phenomena on the right side easier than the left.

The patient always knew where the cramp would end. No matter whether it commenced in the right arm or other part of the body, it must proceed to the right leg before leaving him, on the lower third of the tibia, where the bone appears to have been broken; a scar still exists, where pressure will induce the attack. This would appear to be an increased growth of nervous substance on the surface of the bone, for after its removal by the knife and chisel, the fits having entirely disappeared.

There is strong evidence to show that there was traumatic epileptoid neurosis in this case, combined with hysteria of a common character that could be induced through this scar.

Recuperative Power of Nature in the Eye.

Prof. Mauthner next gave the Society a lecture on the power of Nature in many hopeless cases where interference would be reprehensible, and illustrated his remarks by recording a few cases which have come under his personal notice. The first was a young man, æt. 16, who came to him complaining of headache. On examining the fundus he found both eyes light blue, the retinal veins widely dilated, power of vision of left eye normal, right eye one-eighth. In answer to questions about injury to the head, mother said that when he was a child of three years he fell from the table on to the floor, and since that time has complained off and on, of pain in the head, vomiting and appearing white. A traumatic chronic inflammation at the base seem to be the cause of the ocular disturbance. In spite of all treatment the lad became worse, epileptic attacks, ensued, the ocular nerve was so much reduced that perfect blindness was almost reached. The limitation was concentric, the power of vision in right eye 6·60, left 6·36; after this time rapid blindness ensued; nothing but exudative shrinking of the nerve could be expected, the patient was attacked with variola; vision gradually improved till the following year when it reached 6·4, but the epileptic attacks did not cease. Again in the left eye a large segment of the upper and internal side became light blue, while the other part had a rose colour. At the line of demarcation the blue colour stood far in advance of the white, which in all cases is a strong indication of nerve destruction in the eye. It may be presumed that the variola poison was the active agent in removing the exudation from the base of the cranium.

◆

The Operating Theatres.

ST. THOMAS'S HOSPITAL.

Radical Cure for Double Inguinal Hernia—Extra Peritoneal Gut in the Left Side.—The patient operated on by Mr. Anderson was a man, æt. about 30, who had been suffering from a large scrotal hernia on the right side for some years; a small hernia on the left side was of more recent origin. The right side was first operated upon; the sac was isolated, ligatured close to the internal ring, and cut off close to the ligature, no sutures were used for the pillars. The wound was then closed. The operation on the left side was next commenced. On cutting down over the external ring, a piece of intestine was found, nearly the whole circumference of which was uncovered by peritoneum; it was thick, presented a strong longitudinal muscular coat uniformly distributed as far as could be seen, and there was no trace of sacculation. Above this was a peritoneal sac; this, on being opened, was found to invest the upper third or fourth of the exposed intestine, and could not be detached from it. The opening in the sac was sutured. On the outer side amongst the elements of cord was found a small serous tube, not communicating with the peritoneal tube before mentioned, nor with the peritoneal cavity; but, from its relation with the cord, appearing to be a relic of the funicular process; this was isolated and removed. The wound was then closed. Mr. Anderson remarked, with reference to the condition found on the left side, that the case appeared to be very remarkable, if not unique. The hernia, he pointed out, was sacless and direct; here was a portion of gut almost entirely uncovered by peritoneum passing through the external abdominal ring; it was hard, he thought, to say what portion of intestine this represented; from its great thickness, it could only have been large intestine, and structurally it bore a close resemblance to rectum, but it was possible that it might have been a misplaced sigmoid flexure, or even cæcum. Of course, nothing could be done to effect a permanent cure, and nothing was left but to close the opening in the peritoneum. The tube found on the outer side almost certainly represented the processus vaginalis, which on the right side in all probability formed the sac. With reference to the operation on the right side, Mr. Anderson mentioned that he had for the last ten years performed all operations for radical cure by simple ligature of the sac at the level of the internal abdominal ring. This he had done on anatomical grounds, as in the absence of a tube the structural arrangement of the abdominal wall naturally resisted the protrusion of a hernia in the inguinal region, and in any case a passage must be left for the cord, and even if the cord be transplanted, as has been recently practised, the surgeon was merely replacing one aperture by another. An operation for strengthening the abdominal wall by sutures could have only a temporary effect, whilst some operations would even tend to weaken the resistance. Suture of the external ring alone would be obviously of little use even if it could produce a permanent effect, because an intestinal protrusion might still enter the canal, and it would possess all the dangers of a hernia which had escaped through the external ring. It is, in fact, he thought, attempting to bolt the front door against thieves while leaving the back door open. Statistics, as far as they go, have not shown any decided advantage from the complicated methods which are still multiplying. It is, he said, of course, difficult to trace hospital patients, but in all of his own cases which he had been enabled to follow for one year or more the cure had been substantial, and no patient had returned with a recurrence.

GREAT NORTHERN HOSPITAL.

Two Operations for Intestinal Obstruction, Inguinal Colotomy and Subsequent Enteroplasty. Mr. Herbert Allingham operated on the case of a woman who had suffered from repeated attacks of obstruction for some years. About ten days previous to the first operation she was admitted to the hospital under the care of Dr. Beevor, for a sudden attack of obstruction which had already lasted about a fortnight. Dr. Beevor at once asked Mr. Allingham to see the case. On examination she presented the following points: aspect abdominal, constantly vomiting, abdomen distended, tympanitic, colicky pains with well-marked intestinal movements. Per rectum and per vaginam examination negative. It was inferred from the history of the case that the obstruction was somewhere in the large intestine, therefore it was thought advisable to perform inguinal colotomy; the abdomen being opened the sigmoid flexure was found to be much distended. Before opening it, however, Mr. Allingham passed his hand into the abdominal cavity hoping to find the nature of the obstruction. No growth or band being found in the pelvis, the descending colon and as much as possible the transverse was handled with negative results. As the large intestine was found to be so distended, Mr. Allingham inferred it was a case of over distension, giving rise to paresis of the gut and thus causing the symptoms of intestinal obstruction. The sigmoid flexure was therefore brought into the wound, fixed there, opened, and a Paul's tube inserted. Next day, the obstruction not being relieved, Mr. Allingham decided to open the abdomen on the right side over the cæcum. This was done by an incision four inches long on the right linea semilunaris. The cæcum was found to be distended, the hand was introduced into the abdomen and the ascending and transverse colon was thoroughly explored. No stricture being felt, it was determined to carefully hunt through the small intestines. Commencing at the ileo-cæcal valve the small intestines were carefully pressed through the hand and as examined returned into the abdomen. At a point about the junction of the jejunum and ileum it was found that two coils of intestine were bound together to the extent of about two inches by firm adhesions. With great difficulty the coils were separated and in one of them was discovered a firm fibrous stricture. The gut above this was greatly dilated. The stricture being of an innocent nature it was determined to perform enteroplasty rather than resection of the stricture. The strictured gut having been pulled well out of the abdomen and that cavity protected by sponges, a longitudinal incision was made through the gut and the stricture at a point opposite the mesenteric attachment; the incision was about three inches long and opened the intestine; the longitudinal incision was then converted into a transverse one by catching hold of each side of the centre of the longitudinal incision with clip forceps and drawing those two sides apart. The mucous membrane of the *upper side* of the now transverse incision was united to the mucous membrane of the *lower part* of the now transverse incision by many interrupted silk sutures. Mr. Allingham was unable to put in Lembert's sutures to bring the serous surfaces together because the peritoneum had been stripped off the gut in separating it from the other coil of intestine. There was much oozing of blood from the lower peritoneal surface—this was arrested by swabbing it over with perchloride of iron. The gut was then washed and returned into the abdomen and allowed to rest just under the incision in the abdominal wall which was united in the usual way with the exception that one stitch was left loose and the wound allowed to gape at this point; this was done in the hope that if there were any leaking from the sutured gut it would find its way out of the abdominal cavity. Mr. Allingham said that the interest of the case lay in the fact that although the stricture was in the small intestine the large intestine was enormously distended. He remarked that although this plastic operation had been performed in cases of stricture of the pylorus, he believed that, as far as he knew, it was the first time it had been performed for stricture of the intestine. He drew attention to the advantage of this operation in that it was less risky and less severe than resection of an innocent stricture, and by converting the longitudinal incision into a transverse one a large piece of healthy gut was let into the free part of the bowel, the stricture being divided and falling behind. It is satisfactory to state that a week after the patient was doing perfectly well.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 9, 1894.

THE PUBLIC APPRECIATION OF MEDICAL MEN.

The meeting held on Thursday last at the Prince's Hall may be said to have marked an era in the history of the profession. The occasion was one in which many notable men, under the presidency of His Royal Highness the Duke of Cambridge, foregathered for the purpose of formulating some scheme to perpetuate the memory of our distinguished *confrère*, the late Sir Andrew Clark. Undeniably an added interest was lent to the proceedings by the presence on the platform of the ex-Premier, Mr. Gladstone, whom all the world knows had been guided by Sir Andrew Clark through many a shoal of sickness and ill-health. But the appearance of Mr. Gladstone for the purpose of supporting a memorial scheme on behalf of his late "trusted physician" had a pathetic side to it which could scarcely have passed unnoticed by the majority of those who were present. The aged ex-Premier, himself suffering from the inevitable infirmities of a long and arduous life, and inferentially carrying the conviction with him to his audience, that within a short period he would have to seek the aid of surgery in order to regain his lost vision, still made the effort to be present in order to speak a word in favour of his friend, "not only," as he expressed it, "on the grounds of duty and respect, but of gratitude and personal affection." A greater tribute than this to Sir Andrew Clark's worth, in the opinion of Mr. Gladstone, could scarcely have been paid. It seemed to throw some light upon the personal relationship which had existed between the distinguished physician and his still more illustrious patient; it tended to show that, diverse as were their paths in life, a mutual bond of union had sprung up between them which nothing could ever have severed saving death. Probably only those who are intimately acquainted with Mr. Gladstone have any knowledge of the depth of feeling which the loss of his physician has caused to the ex-Premier. Indeed, it is not difficult to gather from the remarks in his speech at the meeting something of what the effects of this loss has been to Mr. Gladstone. He touched upon many points bearing upon his relationship with Sir Andrew, and more than once appeared to hint at the void in his life which the death of Sir Andrew had created. Perhaps the full pathos of the panegyric upon his lost friend was reached when Mr. Gladstone said, "He followed me from month to month, and week to week, and never more than in the last year of his existence, with something that resembled a paternal affection." But in bearing testimony to the value of

Sir Andrew Clark and his "noble life," Mr. Gladstone took the opportunity to pay a tribute to the medical profession which, in breadth of appreciation, has, we may safely say, never before been equalled on any public occasion by any public man. "The profession itself," he remarked, "is one with regard to which it is impossible, I think, not to be conscious that its position in our generation, and in some generations previous, has been a position continually advancing and continually rising. . . My own life is long enough to have enabled me to witness, and in some degree to measure, the change which has taken place. I have had the good fortune of knowing many distinguished men in the profession during the past three score years; I have seen also a great change in capacity, in attainments, in competency to deal with the difficult and almost insoluble problems which are continually presenting themselves to the mind of the medical man." These are undoubtedly words the full power of which the medical profession will be able to appreciate, and the fact that they were uttered by, perhaps, the most representative man of his time, endows them with a value which few would be prepared to dispute. The death of Sir Andrew Clark has been a loss greatly felt by the profession, as well as by the public. But the proceedings last week, at the Prince's Hall, may be said in some measure to have detracted from the loss which the profession has sustained, for in honouring the memory of the late Sir Andrew Clark in the manner which the meeting in question did, the profession has been highly honoured, inasmuch as not only were men present whom to the world are famous, but so representative was the gathering of those belonging to all sides of public opinion in this country that it may truly be said that in many respects the occasion was one which was unparalleled in the history of the profession.

◆

CHEMISTS AS PRESCRIBERS.

In the current issue of *The Asclepiad* Sir B. W. Richardson discusses the subject of medical quackery under the above heading, and after describing the several classes of quacks as terrorists, homicides, nostrummongers and specialists, he devotes a certain space to counter-prescribing, concerning the regulation of which he makes several suggestions which call for some amount of criticism. Commenting on the difficulties which must at times beset even the most conscientious chemist who declines to usurp the office of the physician as a prescriber, Sir Benjamin Richardson professes to see no remedy for the dilemma which thus occurs from time to time other than that of legalising the practice of prescribing "in the hands of a specially elevated and examined class of practical pharmacists." It is inferentially assumed in the article that an examination similar to that now obtaining at the Pharmaceutical Society, and supplemented by a further test in the subjects of examination, less midwifery, at present required for a medical licence would be sufficient guarantee of fitness on the part of successful candidates, for the exercise of the wider powers thus to be conferred. But it is fair to inquire whether this would certainly be the case; for it undoubtedly would mean that such qualified chemists would assume, as of right, the full prerogatives of medical men to the extent that these were capable of being exercised with the barrier of their counter between themselves and their patients. Nor does the proviso that out-door visiting should be prohibited to such physician-pharmacists necessarily mean that their attentions would not be given to the diagnosis and treatment of even serious ailments. If, therefore, they can be qualified to deal satisfactorily and safely with the subjects of disease, to the extent of determining the nature of their suffering and the remedies appropriate to their relief, together with the details of their administration; and this after the modified education in medicine, surgery, and pathology which is implied in the fact that such practitioners will be still unqualified to seek admission to the Medical Register; then it naturally arises to inquire how the privileges and powers thus gained differ save in technical details from those pertaining to fully equipped physicians and surgeons? The duty of prescribing is wholly apart and widely removed from that of preparing a prescription; and while the person entrusted with the latter duty needs to be deeply acquainted with the qualities, the actions, and the uses of the remedies prescribed, in order to the most efficient performance of his special functions as a dispenser, he will still fall short of knowing *what* to prescribe in different circumstances of disease, which can come only from practical acquaintance with the natural history of disease as it is studied in the wards and in the post-mortem room under the skilled direction of competent teachers. But such a method of gaining the requisite information is impossible to pharmaceutical students for many and obvious reasons; and so long as the conditions now obtaining rule the preparation of candidates for the two professions, it will certainly remain so. The question of counter-prescribing, nevertheless, remains a subject of anxious consideration; not alone because of the injury it possibly causes to the profession of medicine by withdrawing legitimate practice to the chemists' shops, but also on account of the possible mischief to the public arising from the application of untrained and unskilled knowledge to their ailments. It is so rarely that we are in a position to do other than admire and approve the suggestions that Sir Benjamin Richardson makes in his serial, *The Asclepiad*, that it is with a feeling almost of diffidence that we venture to question the wisdom of his advice in the matter in question; but the remedy for the existing evil is to be sought, we cannot but think, the process in of "levelling up," as he himself insists, though not on exactly the lines indicated. Rather will it be by creating a stronger fellowship between the two branches, and by arousing in pharmacists a desire to do their share of the work in the most perfect way attainable without the assumption of claims that belong of right to the prescribing class alone.

◆

BUDDING ANTI-VACCINATIONISM.

The sentimental sympathies of the South Dublin Guardians with the poor oppressed anti-vaccination martyr, to which we called attention last week, have had a cruel wrench from the Local Government Board and from public opinion, and the result has been that the Guardians have hastened to repair their error and to immolate the martyr. No doubt we shall have the usual show performance at the police-court, when the apostle of liberty to spread small-pox will take the *rôle* of Ajax and will defy the lightning, and will insist on his furniture being seized at a time of day when there will be plenty of people about to look on and sympathise. At any rate, it is well that the toast-and-water sentiment of the South Dublin Guardians should be laid aside for the present. We learn from the speeches of the anti-vaccinationis's that one of the 161 unions in Ireland, the Enniscorthy Union, has declared for them. *Cadet questio !!* Why discuss vaccination any further when the Enniscorthy Guardians have pronounced its doom ?

One of the disciples of anti-vaccinationism in Dublin (there appear to be only two) writes : "When such men eminent in the world of medicine and science as A, B, C, D, E, and F [we do not like to mention names lest our criticism might offend], who have minutely studied the question, declare vaccination to be delusive, dangerous, and deadly," what more is to be said ? Shall we be forgiven if we say that, with an intimate general knowledge of the medical profession and scientists extending over nearly forty years, we have never heard of some of these "men eminent in the world of medicine and science" and, with one exception, what we know of the others does not inspire us with unflinching trust in their knowledge or judgment ? A is not to be found in the "Medical Register" or Medical Directories, and we never heard of his "eminence." B was a chemist and physicist of the highest rank until he fell within the same influence as that which overwhelmed Stead's individuality. Since then he has subsided into a believer in "spooks" and all the rest of it, and he may be omitted from consideration in the vaccination controversy. C (if we are right in our identification of him) was once entitled to respect as a scientist, and when it is shown to us that he has declared "vaccination to be delusive, dangerous, and deadly," we shall be ready to offer due homage. D we cannot identify, there being 41 practitioners of that name in the "Medical Register," none of whom we ever heard named as an anti-vaccinationist. E we know. He has always posed as a general popular sceptic in everything medical, and his papers are models of heterodoxy, for the sake of heterodoxy. We shall not do violence to his reputation by declining to recognise him as "eminent" in anything. Last comes F, a gentleman who is the special apostle and organiser, paid or unpaid, of anti-vaccinationism and, so far as we know, has not, and never had, any other scientific speciality whatever. Thus it appears that, out of the whole number of medical practitioners in the kingdom (31,644 in number), and the infinite multitude of medical practitioners and scientists throughout the world, the anti-vaccinationists can only muster six persons with the scientific record which we have presented. Stay ! We make them a present of one other in the person of a gentleman who was not long since struck off the "Medical Register" for "infamous conduct in a professional respect," but is, nevertheless, an untiring public exponent of anti-vaccinationism.

Notes on Current Topics.

An Historical Instance of Synostosis.

A WRITER in the *Century* magazine for last month makes some interesting remarks upon the anthropological features of the skull of Sir Walter Scott, the famous novelist and poet. As, of course, is well known, Sir Walter was lame, and the author says the peculiar shape of the skull is closely associated with his lameness ; "both were due to a congenital error in bone-making. When about eighteen months old he had a slight illness, caused by dentition. On recovery he was found to have lost—as was thought at the time—'the power of his leg'; the real fact being that the child refused to move a suffering limb. From some cause, probably congenital, and brought into action by dentition, the process of bone-making was arrested, inducing swelling and shrinking of the limb and lameness, from which he never recovered, though it did not prevent great activity upon his feet. The defect or fault in the bones of the leg extended also to the skull, in other words, error in bone-making then showed itself. Post-mortem examination revealed that there had been a premature union of the two parietal bones along the sagittal suture, due to an arrest of bone-making along the edges of the suture, which closed like a vice upon the expanding brain. This closure affected only the sagittal suture ; the coronal suture was left free, and the brain pushed the vault of the skull up and back, creating the oblong shape so noticeable in the mask and so similar to that of the microcephalous idiot." The author reasons from this that had synostosis not occurred Sir Walter might have been an infinitely greater man than he was. The statement, however, that the lameness was due to faulty bone-making is open to doubt. A much more probable explanation is that the symptoms were due to an attack of infantile paralysis. Another curious feature to which attention is drawn is, that some of Sir Walter's senses were very far from being acute. He had hardly any ear for music, and his olfactory sense, according to Lockhart, was somewhat primitive. When, for example, venison happened to come to the table in a condition of such "highness" as to make the guests uncomfortable, Scott remained quite unconscious and indifferent to the pervading effluvium. Some evidence, moreover, appears to exist that his sight was faulty The author makes the most of the interesting study of speculating upon the effects of the synostosis upon the life-work of the distinguished novelist, and what the result would probably have been had no premature union of the bones of his skull taken place.

The Dalrymple Home for Inebriates.

THE Committee of the Dalrymple Home for Inebriates at Rickmansworth has just issued its tenth annual report. During the past year forty patients were admitted, of whom twenty-three were "under the Act" and seventeen private patients. Of the forty cases admitted twenty-one entered for three months, fourteen for six months, and only five for the period at present allowed by the Inebriates' Act. It is worthy of note that the health of the patients generally was uniformly good; one case, however, necessitated being discharged owing to progressive phthisis, and another for a condition bordering on lunacy. It is evident that the Committee experiences some difficulty in carrying on its good work, in consequence of the incompleteness and inefficiency of the present Act. The recommendations which have already been laid before the Home Secretary for amending the legislation mainly refer to compulsory curative restraint in respect to habitual drunkards, but nothing has been done so far officially towards taking the recommendations in question into consideration, although they have been generally approved. We regret to see that the Committee has had to commence its year's work with a deficit of upwards of one hundred and fifty pounds, but in view of the financial depression of the past six months, this is by no means so bad a record as might have been the case.

Medical Men in the Law Courts.

The cases in which medical men, either as plaintiffs or defendants, have figured in the Law Courts of late have been something phenomenal. Libel actions between one another, prosecutions for alleged grievances in the sale of practices, prosecutions for the payment of damages on the grounds of alleged negligent treatment, may be cited as instances of the regrettable manner in which recently the profession has been *en evidence*. Then, nothing could be more unfortunate than the serious *contretemps* which has arisen in connection with the Council and the Members of the Medical Defence Union. However, it is sad to have to note that differences between medical men are not confined to this country, for a short time ago a libel action between two members of a hospital staff in Castlemaine, Victoria, N.S.W., was fought out to the bitter end. The basis of the action was that each accused the other of incompetence in the treatment of a case of retention of urine. After lasting seven days, the jury returned a verdict for the defendant, with costs. In the counter claim the judge divided the charges into eleven paragraphs, on the fourth and seventh of which the jury found for the plaintiff with a farthing damages—a verdict which carried costs with it. The judge took the opportunity to say that never in his long experience had he seen such a trivial case so elaborated, and added that the actions should never have been brought. Thus, after seven days' litigation, both of these medical men were saddled with enormous costs, without having gained the objects for which the actions were brought. Moreover, it was quite evident from the remarks of the judge that no public sympathy was shown for either of them.

The Scottish Colleges and a University Degree.

The Colleges in Scotland, in whose hands the granting of the triple qualification lies, appear to be dangerously supine with regard to a matter which would appear almost to threaten their very existence. One of the ordinances of the Scottish Universities Commission, which is now lying on the table of the House of Commons, if passed will, as at present drawn up, preclude the licentiates of the College from obtaining a University degree. Of course, up till now this privilege has not been very much sought after; but if, with a London University founded, capable of stamping the hall-mark of a University Education on college-taught students, not to speak of the competition of the four Universities in Scotland on their new and more popular basis, the Scottish Colleges do not bestir themselves before it is too late, their extramural schools of medicine will dwindle, and their licentiates, from whom a large portion of their revenue accrues, will become as rare as snow in summer. In the past the competition between the extramural schools, with their independent teachers, and the Universities has been of great service to both. With the prospect of a University degree at the end of their college course students might still be induced to stay outside the University walls. Without it, in all probability, London would engulf them in her insatiable maw, while the Universities, left alone, would become mere money-making machines, even more so than they are at present. The degree proposed to be given is that of St. Andrew's University, and the authorities of that ancient seat of learning are quite willing to confer it if proper powers be obtained. It is time that the Colleges, in their own interests, should attempt to attain their ends, and, by concerted action, if possible, strive to rest their medical schools on a surer foundation.

The Harness Belt Libel Action.

Another action arising out of the fraud alleged by the *Pall Mall Gazette* to have been practised by Harness, of the Electrical Battery Company, has just been settled by Mr. Justice Wright and a jury in the Queen's Bench Division. The plaintiff in this instance was Mr. Fleet, a solicitor, who sued the proprietor of the *Pall Mall Gazette* to recover damages for libel The passage which was regarded as libellous ran thus: — "Besides the *Electrical Review*, *Science Siftings* was involved in the circular issued to the newsvendors. *Science Siftings* had been even more outspoken in its criticisms of the *système* Harness than the *Electrical Review*, and Harness thought himself safe in using a writ to stop the articles. But *Science Siftings* took an exceedingly smart step, and counter-claimed for large damages against Harness and against one Augustus Fleet, his solicitor, who had been ill-advised enough to sign the circular. But Harness tamely crawled down to the office in Fleet Street, with his solicitor, determined to square the case. Meanwhile his hapless solicitor, who was plainly uncomfortable, and who had begged, cost what it might, to have his own name kept out of the action, interposed vainly to prevent his client's making a fool of himself. Before Harness left he paid up damages to the extent of £1,000 and £300 costs, embracing both the claim and the counter-claim in which scandalous allegations were made." In summing up his lordship said he agreed with counsel for the defence that newspapers performed important public functions, which it was almost impossible to perform effectually if every word they wrote and every reference they made was to be made the subject of an action. The jury found for the defendant, and judgment was given accordingly.

The Increase of Diphtheria.

It is satisfactory to note that the Metropolitan Asylums Board is providing additional accommodation for patients suffering from diphtheria. The rapid increase of that disease, not only in London, but throughout the country generally, has been strikingly shown in the annual report of the Asylums Board. The total number of cases in the metropolis during 1891 was 5,907, a sufficiently large return. In the following year, however, the numbers rose to 7,786, while in 1893 they reached the very serious figure of 13,026 cases. These facts may well cause anxiety to those interested in the state of the public health. They point, moreover, to imperfect preventive measures, whether aimed at the originating causes of the malady, or at its subsequent spread among the community. The etiology of diphtheria is still obscure in many of its phases, and might with advantage receive more attention at the hands of the Local Government Board. The study of this disease, its origin, its methods of propagation and of dissemination, would, from an economic point of view, repay the expenditure of large sums upon a thoroughly scientific investigation.

Woman Medical Enterprise.

A Miss Lilias Hamilton, a medical woman, has just embarked upon an enterprise which may or may not result advantageously to herself. She has left India for the purpose of undertaking the medical care of the women of Ameer Abdurrahman's household. Kabul has never had much of a reputation for its favourable reception of English persons, and an Englishwoman, unprotected, albeit nominally under the protection of the Ameer, is scarcely likely to alter the record in this respect. It is not surprising, therefore, to find that the Indian Government has informed this enterprising, though we cannot but think foolhardy lady, that she has joined the Ameer's household at her own risk, disclaiming at the same time all responsibility for whatever may happen to her. Miss Hamilton is promised, on her arrival, a personal guard of six soldiers, three of whom will always accompany her whenever she goes out. Probably everything will go smoothly so long as the guard is maintained, and thus an outward show of respect and consideration for their ruler's latest importation might induce in her a sense of security, ending, perhaps, in the relinquishing of the official presence of the soldiers as unnecessary. Then the time of the crafty Afghan would come, and the hated presence of one of English blood would be in peril of summary removal at the hands of a fanatic crowd. Nominally, the engagement of Miss Hamilton's services is for a period of six months, and quite possibly, of course, an agreement has been drawn up between the Ameer and herself to this effect!!! But the conviction in our mind is very strong that the case cannot be more aptly described than by the familiar words, "Will you walk into my parlour?" said the spider to the fly!

The Cutaneous Absorption of Guaiacol.

Recent investigations go to show that guaiacol is readily absorbed by the skin. MM. Linossier and Lannois have found that the process is a very rapid one; a quarter of an hour after the drug had been applied to the skin it was detected in the urine, and the elimination was not complete at the end of twenty-four hours. Analysis showed that in the urine passed during the whole of one day, no less than 55 per cent. of the guaiacol applied was present. Investigation showed, morever, that in order to obtain the maximum degree of absorption it was necessary to cover the part of the skin over which the drug had been spread with an impermeable dressing and some layers of cotton-wool, in order to raise the temperature of the part. This method of administration seems to possess some advantages, and is especially indicated as far as guaiacol and creosote are concerned, the use of which beyond a certain extent is limited, owing to the gastric disturbance excited when the drugs are given by the mouth.

The Case of Dr. Herz.

The French Government have abandoned the extradition proceedings against Dr. Herz, so that there will be no more occasion for the great grandsons of Nelson's powder boys, or boatswains, or post captains at Trafalgar, to write agony letters to the *Times* for the purpose of drawing public attention to the hapless position of the interesting exile and obtain a gratuitous advertisement for themselves. Dr. Herz is still at Bournemouth, and we believe is in much the same state of health as that in which he reached our shores. There is some comfort in the reflection that the possibility of a public scandal was avoided by the decision arrived at to make no attempt to bring him to Bow Street for the purpose of carrying out the extradition proceedings. Dr. Herz was pronounced to be suffering from a serious organic affection, and it would have been contrary to all the dictates of humanity to have exposed him, while in an alien country, to conditions imperilling his life.

A Sanitary Committeeman's Insanitary Property.

A member of the Sanitary Committee of the Board of Works, St. Saviour's, Southwark, has lately been fined by a London magistrate. By a curious irony of fate he was convicted of owning property unfit for human habitation. His premises were proved to be in a dilapidated condition, the roof being defective, in fact, the sky could be seen through the roof, the walls were without plaster, and the closet defective and without water. The defendant, who did not trouble to appear in court, was fined in the substantial sum of £20, and at the same time a closing order was issued. As a contemporary very justly remarks —"If the notions of the defendant as to wholesome houses may be gauged by the condition in which he keeps his own property in question, the value of his services as a sanitarian to the parish of St. Saviour may well be questioned." It is just possible he may be one of a class of landlords who regard the holding of office on public boards as a kind of insurance against inconvenient inquiries.

The Restraint of Small-Pox Patients.

The fever hospital authorities at Bristol appear to have a specially troublesome set of patients. It was only a short while since we reported the case of an inmate who was fined by the magistrates for leaving the hospital and walking about the neighbourhood. In commenting upon that occurrence we pointed out that the discipline must be lax, and that there should be some further inquiry into the case. Another case has now been reported from the same institution. It appears that a young man and his wife were under treatment for small-pox. For some reason or other the husband was annoyed with the other patients, so he and the partner of his troubles got over the difficulty by simply going out of the place and walking through the streets to their own home. Surely the hospital authorities have a right to interfere in a case of this kind, and prevent patients leaving the hospital under such circumstances. If they do not possess that power the sooner the admission to fever hospitals is made conditional, or the power of retention be conferred legally, the better for everyone concerned. The Bristol magistrates, we are pleased to observe, inflicted a fine of three guineas upon this impulsive young man.

The Meteorology of Cholera.

With undoubted presence of an epidemic of cholera at Lisbon, albeit mild in form as it appears to be, it behoves all the sanitary authorities in this country to be well on the alert, and prepared for a possible invasion of the foe. It is not, however, without interest at the present moment, when the disease is beginning to assert itself again, to refer to the meteorological conditions which seem to favour its progress. According to Surgeon-Captain Herbert, who contributes a paper on "The Meteorology of Cholera in Madras Presidency" to the current number of the *Indian Medical Gazette*, the most important indices of the weather generally are the registers of the barometer and rain gauge. Investigation shows that they bear a very definite relationship to cholera activity in India. The conclusions arrived at are that the severest cholera years are marked by drought, especially in the summer monsoon; with cholera severe only in the cold weather there is an average south-west and an excessive north-east monsoon; cholera and non-cholera years have more rain than usual in the summer, and commonly, though not always, a li ool-weather rainfall. In brief, drought in the earlier monsoon is favourable, and excess unfavourable, to cholera prevalence. The relationship of the rainfall to cholera is not so easy to explain. In the months of October and November, for example, when the heaviest rain of the year falls, excess is favourable to the disease, provided the earlier rain has been light. Nevertheless, the cold weather cholera does not usually attain any intensity till the heavy rain has ceased. Moreover, when the cholera reaches its height in December (as was the case in the years 1875 and 1891) the late rains have been less than normal. It is worthy of note that cholera does not make a fresh start after complete absence for some time until some rain falls. The deduction, therefore, is that the causes which favour its occurrence are at work chiefly in periods of light summer rainfall, but the full result is not seen until the ground is drying after the heavy north-east rains.

The Prospects of a Smallpox-Pox Epidemic in Mile End.

Owing to the phenomenal neglect of vaccination in Mile End, this "hamlet" of the metropolis is ripe for an epidemic of small-pox. We believe that there are at least 7,000 persons against whom, for failing to submit to vaccination, the Mile End Board of Guardians could issue a summons if the Board, so neglectful of its duty, was willing to put the law in force. The serious condition of affairs in this respect is further exposed in the recently-issued report of the Medical Officer of Health for the district. Dr. Taylor points out that in the early part of last year it was only through the vigorous and prompt intervention of the authorities that a severe epidemic of small-pox was prevented from developing. As it was, no less than 116 persons were attacked, and of these eight died. In thirty-five cases of children, the medical officers found that twenty had not been vaccinated, ten had been vaccinated, and of the rest, the evidence was not conclusive enough upon either of these points. Of the eight deaths which occurred, five were of unvaccinated persons. Possibly, when it is too late, the Board of Guardians of Mile End will awake to their sense of duty. Nevertheless, it is a sad commentary upon their common-sense and intelligence to have to record that their experience of small-pox in the district last year has had, so far, no effect upon them in enforcing the compulsory clauses of the Vaccination Act.

The Queen's College, Cork.

A "Visitation" of this College is fixed to take place on the 16th of May. This means that Justices O'Brien and Holmes, the Moderator of the General Assembly, and the Presidents of the Irish Colleges of Physicians and Surgeons, will assemble in Cork to hear some complaints against the administration of the College. On this occasion the President, Dr. Slattery, is cited by certain of the professors, and certain of the College Council, to justify himself about matters of which they complain, but no one, but themselves, knows, at present, what these matters are. An interesting point about these visitations, which occur not infrequently in one or other of the Queen's Colleges, is that no provision seems to be made for the payment of the expenses of the visitors who attend. There may be, perhaps, a great deal of honour to be got out of sitting for some days to adjudicate upon the intestine squabbles of such an institution, but it may be doubted whether the honour compensates for the loss sustained by prolonged absence from business. If the Queen's College, or any other public institution, desires to retain the services of arbitrators whose time, brains, and reputation are valuable to it we do not see why the institution should not pay, like any private individual.

Charges of Indecent Assault against Men.

Mr. Lawson Tait recently read an interesting paper before the Birmingham and Midland Counties Branch of the British Medical Association, in which he drew attention to the arrangements which exist in Birmingham for dealing with charges against men, made under the Criminal Law Amendment Act. It appears that all cases in which charges made against males for sexual offences against females are submitted to him by the police authorities for an independent investigation and report. So far, nearly a hundred cases of the kind have come under his notice, and of these, as showing the necessity of full inquiry, he found it necessary to advise prosecution in only six, in all of which convictions were obtained. In about sixty-six he advised that no effort at prosecution should be entertained, and his advice was accepted by the police. The cases convicted included three of injury by the fingers in libidinous assault, two cases of the communication of primary syphilis to young children by genital infection, and one case of precocious pregnancy. Another case was one of rape upon a young child, when the perineum was completely torn through and the septum divided nearly up to the uterus. In this instance the man committed suicide before the police were able to arrest him. The great point, however, which Mr. Tait insists upon is that the Criminal Law Amendment Act should be amended in order to protect boys against being induced by adult women to have sexual intercourse with them. According to Mr. Tait this is by no means a rare offence; "relatively," he says, "I am not sure if it is not as common as its converse." There is no doubt that while every protection is afforded to the female sex by the Act in question, the male sex are placed at a great disadvantage, not only in the manner pointed out by Mr. Tait, but also in the power which women possess of bringing false charges against men. The arrangement, therefore, which the police have adopted at Birmingham for dealing with these cases appears to be one which might with advantage be copied by other municipal authorities.

Dr. H. Down, of Tiverton, who died on Saturday evening, at the age of 72, was for several years Deputy Inspector-General of the Army Medical Department, and went to live at Tiverton, in 1869, where he succeeded Dr. Scott in practice, but retired into private life in 1877.

Death under Chloroform during Enucleation of an Eye.

Chloroform fatalities seem somehow to be more frequent now than they used to be. Another death was recorded last week of a patient who had just submitted to enucleation of the left eye. He was a man of seventy years of age, and was considered by his medical adviser to be quite healthy, and a suitable subject for the operation. In support, moreover, of this view nothing was found at the post-mortem examination to which the fatal effects of the chloroform could be attributed. The medical evidence at the inquest pointed to the fact that the respiratory movements were the first to fail; in other words, the heart continued to beat for some time after the breathing had ceased, but all efforts to restore the respiratory acts, such as artificial respiration, galvanism, &c., were quite without avail. In this case it would have been of interest to examine microscopically the condition of the medulla oblongata with a view to ascertaining whether any degenerative changes had taken place in the neighbourhood of the respiratory centre. This, we believe, is the first instance in which death from chloroform has occurred during the enucleating of an eye.

Unique Condition of Hernia.

In this week's "Operating Theatres" will be found a most interesting case showing the stumbling blocks which may occur in cutting down on a hernia for radical cure. For a surgeon having the experience of Mr. Anderson (who was the operator on this occasion) to say the condition found was remarkable would at once draw attention to it, but when he adds that as far as he knows it is absolutely *unique*, the case merits the serious consideration of all surgeons. Undoubtedly many peculiarities are met with in the numerous operations for the radical cure of hernia, yet they are mostly of a kind for which the surgeon is more or less prepared. But the one which will be found in the "Operating Theatres" is calculated to puzzle any surgeon, and more especially to put his anatomical knowledge and surgical resource to the test, not only on account of the hernia being sacless and direct, but also and principally from the impossibility of knowing what the piece of bowel really was beyond the fact of its being large intestine. If it really were *cœcum* in a *left* inguinal hernia, it would be a parallel to Mr. A. Cooper's case, reported in "Operating Theatres" many months ago, in which that surgeon had to perform inguinal colotomy on the right side through finding no colon on the left.

The Education and Registration of Midwives.

A Special General Meeting of the North of England Obstetrical and Gynæcological Society was held in Manchester, on Friday the 4th inst., to consider this subject, the President, Dr. Burton, in the chair. After some preliminary conversation a resolution to the effect that the Society considered it would be of advantage "if midwives were better educated and also controlled in their practice" was put and carried unanimously.

THE Local Government Board have decided to refuse the application of the Acton, Chiswick, and Hanwell Local Boards for a provisional order to acquire compulsorily certain land in the picturesque village of Perivale on which to erect an infectious disease hospital.

MR. F. BRAINE ROCKSTRO, L.R.C.P.Lond., M.R.C.S., was committed for trial on Friday last at the Alfreton Police-court on the charge of indecently assaulting a patient, æt. 18, in the course of his professional duties. The defendant was at the time acting as assistant to Dr. Stamford, of Tibshelf, and denies the allegations. As the case is *sub judice* we refrain from comment.

AN inquest on the body of Surgeon J. H. Drake, son of the late Admiral Drake, who had committed suicide, was held at Brixton, on Thursday last. Deceased was in a state of despondency and in pecuniary difficulties. A verdict of "Suicide whilst of unsound mind" was returned.

ABOUT twelve months ago the Islington Guardians, at the request of the local Anti-Vaccination League, suspended prosecutions for non-compliance with the Act. Small-pox, in the meanwhile, has increased, and the Guardians have issued handbills urging upon the people the necessity of vaccination.

AT a meeting of the Governors of the Exeter General Dispensary, held last week, Mr. Russell Coombe, F.R.C.S., was elected to the vacancy on the staff created by the death of Dr. M. L. Brown.

THE Earl of Chesterfield has presented a medal, to be called "The Chesterfield Medal," for annual competition by the students of St. John's Hospital for Diseases of the Skin.

THE annual dinner of the Volunteer Medical Staff Corps will take place on Wednesday, May 30th, at the Café Royal, Regent Street, W.

MR. JAMES MASON, of Oxford, has given £500 to the Building Fund of the Radcliffe Infirmary, Oxford.

DR. WILLIAM OGLE has been placed on the Commission of the Peace for the Borough of Derby.

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

POORHOUSE FEES.—In August last, the Medical Officer of the East Dundee Poorhouse being out of town, and his substitute not to be found, the Governor wishing for medical advice for an old woman, who had suddenly become unwell, sent to Dr. Robert Miller, who resided in the neighbourhood. Dr. Miller has now come to loggerheads with the Parochial Board with regard to his fee, assessed by him at a guinea, by the Board at five shillings. The case came before the local Small Debt Court last week, and the Sheriff found for the Board on the ground that there was no contract between them and Dr. Miller, and that the call to do work was a call to do charitable work. It seems to us that Dr. Miller was very ill-advised in the first place in proceeding for his guinea at all, and that an arrangement with the Medical Officer of the Board, whom he really represented on an emergency, would have been preferable. Secondly, the charge of a fee of a guinea for visiting a pauper case in a poorhouse, and, as the evidence brought out, only requiring some stimulant, seems to be high, though it may be legal. In the course of the case Dr. Miller is reported to have made the statement that all insurance companies pay a fee of one guinea, and some two, for each examination. How everyone who does insurance work must wish that this were the case! for most of the offices now only pay half-a-guinea if the sum assured be under £250, or even in some cases under £500. But, on the other hand, the Sheriff's ruling seems peculiar, for surely summoning a practitioner to see a patient is practically a contract, unless, which does not appear in the evidence, Dr. Miller was only distinctly asked to fill the place of the medical officer for this one case. As the medical officer, we suppose, is paid a salary per annum, and not a fee for each case he sees, it seems proper that the onus of such a case should lie on his shoulders, for it is his duty to see that each case is attended to.

UNIVERSITY OF EDINBURGH.—The Summer Session in the Medical Faculty began on May 1st. On that day also the examination in Clinical Medicine for the Final Professional was commenced, the Clinical Surgery examination having been started on April 26th. The writtens will be held on June 18th and 19th, to be directly followed by the orals.

THE members of the Edinburgh and Glasgow Medical Club dined together in Glasgow on Friday night last week.

EDINBURGH MATERNITY HOSPITAL.—Drs. Underhill and Milne Murray have succeeded Drs. Berry Hart and Barbour for the summer months at this hospital; and the new house surgeons are G. A. Macdonald, M.B., C.M., and George C. Sandford, M.B., C.M.

THE LATE MEDICAL CONGRESS AT ROME.—Professor W. T. Gairdner, in opening his summer course at the Glasgow University on the 1st inst., referred to the International Medical Congress at Rome, and his visit thereto. In the course of his remarks he said it was difficult to understand how the great work of Morgagni could have sunk into such a state of medical decadence as that of Italy in the fifties. The magnificently-enthusiastic reception accorded to Rudolf Virchow in 1894 by the whole Italian nation, and the graceful and appreciative *éloge* pronounced by the great German pathologist on John Baptist Morgagni as the first and greatest of his predecessors in well-ordered pathological research, might be taken as marking in a very striking and almost dramatic way the rejuvenescence of Italy in medical science. That Virchow was the legitimate successor of Morgagni in the present day no one can doubt. It might even be doubted whether in any country of the world there is any intervening name which could be placed in the same rank as these two. Yet the marvellous fact was that, in and about 1850, Italy seemed to have lost touch altogether with the lines of progress initiated by their own greatest pathologist, and the art of healing had sunk into a corresponding position of obscurantism. These things were a lesson for us also, if we should ever be tempted to suppose that by casting away or neglecting the foundations of the medical art we could ever hope to improve it in its more practical as contradistinguished from its scientific aspects.

Treatment of Infectious Diseases in Islay.—At a meeting of the Argyll County Council, the attention of the Council was drawn to a serious case concerning the treatment of infectious disease which happened on a farm in Islay a short time ago. The house, occupied by poor people, was burnt to the ground with everything belonging to them, and without the slightest pretence at any compensation being made, beyond the fact that the matter was to be reported to the chief constable.

The late Dr. Samuel Moore's Will.—The will of the late Dr. Samuel Johnstone Moore, 15 Blythswood Square, Glasgow, has now been lodged for registration, and, as already mentioned, the bulk of his estate has been left in trust for the foundation and support of an institution to be called "The Dr. Samuel Johnstone Moore Convalescent Home for Nurses." It is provided, however, that no steps be taken towards the foundation of the trust unless the residue of the estate amounts to £45,000, and if it should not amount to this sum at the date of his death, the income is to be accumulated till this sum has been reached, and then the project is to be carried out.

◆

MEDICAL SOCIETY OF LONDON.

The meeting on Monday evening last (May 7th) the last of the session, opened with an interesting paper by Dr. Walter Carr, giving the result of some 120 autopsies of children suffering from tubercular disease. He concluded therefrom that tubercular disease usually commences in the glands, the liability being greatest in early infancy and decreasing with advancing age. He showed that the disease commenced in the glands in 58 per cent. of the cases. Secondly, he pointed out that tubercular lesions in the cervical glands, as in the joints, may arise by infection through the blood stream, but caseation of the bronchial and mesenteric glands, when primary, is usually, if not always, the result of direct infection from the organ with which they are associated, such affection occurring, it may be, without any local lesion marking the entrance of the poison. He pointed out also that tubercular disease is much more frequent in the thorax than in the abdomen in the proportion of 79 to 29. Caseation of internal glands, from the frequency with which it is met with after death, must often exist alone and quite unsuspected, being in many cases quite impossible of diagnosis. Lastly, he pointed out that prophylaxis was the most important factor in treatment.

Dr. Sidney Martin did not think the author had correctly stated the proportion of cases of abdominal infection, but he admitted that it was often a matter of great difficulty, if not of impossibility, to determine post-mortem where was the point of entry. He observed that in spite of all that had been spoken and written about the infectivity of food, we, as a matter of fact, knew very little about it. He pointed out that with a sufficiently large dose of the poison the animal contracted tuberculosis, a local primary lesion marking the site of infection. With smaller doses the glands became infected without any local lesion to show how and where it had entered. The point of origin of some cases of so-called primary tubercular meningitis or disease of joints might be discovered in small calcified glands in the mesentery.

Dr. Routh opined that the inflammation of the glands which marked certain varieties of infection was an effort of nature to prevent contamination of the organism as a whole.

Mr. Percy Dean read the notes of a case of perforation of a chronic ulcer of the duodenum in a woman, causing acute peritonitis, in which he excised the ulcer and sutured the intestine with complete success. Unfortunately, some time later, just as the patient was on the point of leaving the hospital for a convalescent home, symptoms of intestinal obstruction supervened, due, as it turned out, to a band of fibrous tissue pressing on the intestine. This was operated on by Mr. Eve, but the patient sank and died. Several other perforations and necrotic patches were found post-mortem in the neighbourhood of the band.

◆

MR. GLADSTONE'S OPINION OF THE MEDICAL PROFESSION.

In the course of his speech at the Prince's Hall, London, on the occasion of the meeting held to promote a memorial to the late Sir Andrew Clark, Mr. Gladstone made the following remarks :—

I have the honour to address an audience which is composed, I have no doubt, in no inconsiderable degree, of Sir Andrew Clark's brethren in the noble profession which he adorned. In truth, although Sir Andrew Clark was a person whose name constitutes in itself an ample warrant and apology for a large gathering such as that I see before me, yet I feel also that this gathering is an occasion which associates itself with the profession at large. Undoubtedly it was to me a matter of most lively satisfaction when I observed, as the whole world must have observed, on the death of Sir Andrew Clark the thrill of affection and interest which ran through the whole world. A sense of the heavy loss they had sustained, and a desire to render some worthy and adequate testimony to the memory of Sir Andrew Clark.

The profession itself is one with regard to which it is impossible, I think, not to be conscious that its position in our generation, and in some generations previous, has been a position continually advancing and continually rising. In truth, your Royal Highness, if we could go back for some distance, the other learned professions, as they are sometimes called, undoubtedly had a start of the medical profession. I think as much as four or five hundred years ago, in the very first beginnings of the commerce of the country, the lawyers in scores and hundreds sprang up almost like mushrooms from the ground, and disposed of disputes which necessarily arose wherever property was brought into existence. At that time medical men were hardly heard of. But the position of the profession at the present day has become one of vital and commanding interest to the whole of society, and I anticipate that that interest must continue. While wealth increases, while inventions and discoveries increase, wants will increase and enjoyments will increase, and, in connection with wants and enjoyments, there will, I fear, be a corresponding development of infirmity and disease. And the medical profession braces itself to grapple with the situation which has been created, and continually advances in knowledge, credit, and importance. My own life is long enough to have enabled me to witness, and in some degree to measure, the change which has taken place. I have had the good fortune of knowing many distinguished men in the profession during the past three score years ; I have seen also a great change in capacity, in attainments, in competency to deal with the difficult and almost insoluble problems which are continually presenting themselves to the mind of the medical man.

It appears to me that it was eminently desirable that in a time like this a man such as Sir Andrew Clark should rise to the head of his profession. For after all we require something more than knowledge, something more than skill. We require great devotion to the purposes of the profession ; and that devotion never, I think, was exemplified in a more remarkable manner than in the career of Sir Andrew Clark. I remember a small incident when Sir Andrew Clark had been spending his well-earned vacation at a residence which he temporarily occupied in Scotland, and when the few weeks he allowed himself for retirement were nearly exhausted a friend came to him and supposed he paid him an excellent compliment when he said, "I condole with you, Sir Andrew Clark, on the approaching close of your vacation." Sir Andrew

Clark, looking at him, said, "Sir, I love my profession." He did love his profession with his whole heart and soul. While engaged in that profession he loved it not only with a sincere and cordial but with a chivalrous devotion. (Cheers.) We need not say that the age of chivalry is altogether passed as long as we have, as I trust we may still have, among us men of the type of Sir Andrew Clark. There was no part of him, no faculty, no portion of his time which he did not devote with his whole soul, with the whole strength of purpose he could command, to the great work that was before him, not merely to the attainment of knowledge, but the application of that knowledge to the dimunition of human suffering.

I think the profession, if I may presume to say so, has done well in the determination that Sir Andrew Clark might, in the present age, be taken up by common consent as a typical man, the representative of all that is best and noblest in the profession and in its purposes. In every profession there is something more, I would almost say something more important, required than knowledge and capacity, and that is character. The position of medical men is one which brings them more and more within the intimacies of the family circle, which brings them more and more into the confidence of those for whose benefit they are consulted. In order that they may be worthy of that confidence and may turn it to account it is not requisite merely that they should have studied with fidelity, or even with ardour, the difficult subjects to which they devote their minds. But it is requisite that all these qualities should be exhibited by them in conjunctiun with their professional skill. I cannot help hoping that our proceedings on a day like this will be read extensively throughout the country, and especially I am quite certain that they will be everywhere read by members of the medical profession. Although some of them are advanced in life, many are very young, and I rejoice to think what an honour, benefit, and privilege it is to the young members of the profession to be called upon to contemplate a career and character like those of Sir Andrew Clark.

Dr. Church has shown how in the case of Sir Andrew Clark the boy was father to the man. He says that in his very early days, when he was the merest youth in the town of Dundee, and in the very initial stages of his profession—how at that time he acquired, first, the deep love of his profession, and secondly, that profound sense of religion which attended him through his whole life—which supplied him with his guiding principle and purpose, and which produced in him this singular result, that when his mind had been absorbed in the arduous questions continually brought before him in the course of his practice, it was his delight—and all those who knew him will sustain me in what I say—it was his delight and practice to find a recreation, not in trifles and in frivolity, but in betaking himself, naturally, to the consideration of Divine things. I may say that I have come here to fulfil an office and to pay a tribute, not only of duty and of repect, but of gratitude and personal affection.

Of course I am not a competent judge of the skill of Sir Andrew Clark. What I have seen is his patience, his thoroughness, and his absorption in the case of his patient, as if that one case was the single subject with which he had to occupy his mind. I must add, in my own instance, that I have also had to note a warmth of friendship and assiduous prosecution of the task he had set to himself of watching my health, which I know not how adequately to describe. But I may add this, that though he was a much younger man than myself, he followed me from month to month and week to week, and never more than in the last year of his existence, with something that resembled a paternal affection. It is good to look back upon a life of this kind, and in my own case the recollections, which I shall always cherish during the residue of my life, reach over a period of nearly thirty years. Sure I am that whatever happens, whatever may have been the past advances of the medical professfon—and they are great—whatever may be the future advances of that profession—and in all likelihood they will be greater still—there never will come a time when that profession will not be justly satisfied and glad to have recorded upon its annals a name such as the name of Sir Andrew Clark.

◆

CHINESE ETHICS AND PHILOSOPHY.

In the course of a paper read by Surgeon-General Gordon at the Victoria Institute, on Monday last, some few remarks occurred which will doubtless be of interest to our readers. Thus, according to what may be called the Code of Domestic Hygiene of the Celestials, too great an anxiety acout the health of the children is an excess into which many parents fall. Has a young child the least indisposition, he is immediately surfeited with medicines and cordials, his constitution thereby ruined, his health impaired, his days shortened. He observed that in ancient times, granaries and other provisions against famine were kept up under the orders of government, soup kitchens, and various charitable organisations maintained; that in towns and cities hospices for the aged, orphanages, and hospitals for the blind still exist.

In quoting from a "Collection of Maxims, Reflections, and Examples of Morality," the characteristics of a charitable physician, according to the Chinese ideal, were given to this effect, namely,

"Yen Yang had, by his application, rendered himself a very skilful physician, but it was with a view to exercise his profession in charities. He not only never refused his medicines to any who asked them for their diseases, but if the patient was poor, he also gave him some charity that he might procure the necessary aids in his sickness." A second instance was that of Kin Ko:—"A physician of great skill, to which he added equal disinterestedness and an uncommon charity. Whoever called him, he immediately ran to assist them, and this at all times. He saved the lives of a vast many poor children, and he had a singular talent for this. If any poor patient stood in need of *jin serig* (a), or any more costly remedy, he furnished it at his own expense; he thereby saved the lives of a great number of people." From which the fact appears that in China, as elsewhere, charity and philanthropy were personified in the worthy professor of art and healing.

Respect for labour is a cardinal principle in Chinese ethics. With that people labour is held to be the natural inheritance of man, as it is, also, of all created beings. It is a condition of nature, and the essence of man. "It is a necessity, but when its end is not understood, it becomes a punishment." Labour, whether manual or mental, is held to be the duty, as it is the privilege of man. From times the most ancient, this has been so; agitators and others who oppres the workers have been excecrated, while the national characteristics alluded to continue even to our own day. "To stop the hand is the way to stop the mouth." Such is the teaching of a Chinese familiar proverb. In a country, also, where the youngest cannot afford to be idle, there is observable among the young an air of staid gravity quite beyond their years, the reason being that they are early under obligation to take their parts in the serious business of life. Man, according to Chinese philosophy, is from the nature of his being, a creator and a worker. The sure way of ennobling labour is to show its intimate agreement with natural laws, but the operation of these laws must not be set at nought by other laws, civil or political.

According to a Chinese song, "When the sun begins his course I set myself to labour; when he descends below the horizon I sink into the arms of sleep. I quench my thirst from my own well; I feed on the fruits of my own fields. What can I gain or lose by the power of the Emperor?"

The influence of doctrines such as these by hereditary descent through many generations has been to stereotype in Chinese character a fitness for steady industry and perseverance, which, when accompanied, as it for the most part, is by extreme frugality of habits, renders the individual thus trebly endowed the dangerous, and often successful, competitor in industries which the Chinaman has proved himself to be. In his own country, and more especially in some of its largest cities, it is no uncommon thing to see one portion of a family of artisans pursuing their special occupation throughout the entire hours at daylight, and other members take up the same work at nightfall, and so continue it till morning, and so on continuously, for they know not the Sunday's rest.

(a) *Panax quinqiufolia*, an esteemed and costly drug.

Correspondence.

[We do not hold ourselves responsible for the opinions of our correspondents.]

A NEW MEDICAL GRADE.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You wrong me. The suggestion you criticise in your last week's impression is word for word the same as was spoken by me years ago in the speech to which you refer. The suggestion was then, as now, all, and altogether towards the elevation and advantage of every practitioner of medicine. It proposes a mode of meeting a national necessity and public want (which, *nolens volens*, must be satisfied) by enforcing elevation and soundness from the lower to the upper, instead of declination from the higher to the lower; nay—as we see now in sixpenny shops kept by fully qualified men—to the lowest grade.

I pray you think on the matter without prejudice, and I am sure you will credit me still with being, what I hope I have ever been, and ever shall be, the faithful servant of the profession in which my life has been cast, and the best interests of which are my first consideration.

I am, Sir, yours, &c.,
B. W. Richardson.
25 Manchester Square, London, W.,
May 5th, 1894.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I have pointed out that those who advocate the so-called "registration of midwives" are in reality aiming at the establishing of an inferior order of midwifery practitioners. It has, however, remained for Sir B. W. Richardson to propose in the May number of the *Asclepiad*, p. 371, the formation of an inferior order of *medical* practitioners. He there says:—"And I prove, hold that the time has come when the difficulty of counter-prescribing should be met, not by levelling down, but by levelling up; that is to say, by making such prescribing a legal practice in the hands of a specially elevated and examined class of practical pharmaceutists. . . . The qualification thus granted extended solely and legitimately to counter-practice, never to outdoor visiting, would at once smooth away the present difficulties and persistent annoyances." Is it not a great pity that Sir B. W. Richardson should make so down-grade a proposal? I quote it to show the tendency of some consultants to rob the general practitioner of his work, and to show that he evidently wishes to benefit and encourage "prescribing" chemists by filching a share of the medical practitioner's work. Might I remind Sir B. W. Richardson that the time of the *partially* educated and *singly* qualified practitioner has ceased. Even in France, by their Medical Act 1892, the grade of the partially educated *officier de santé* has been put a stop to; while as regards the employment of midwives Her Majesty's representative in France has reported as follows;—"At the present time medical men attend many more deliveries than formerly, and are gradually taking the place of midwives." Why, therefore, should England be asked to take a backward step in medical and midwifery education and practice? The office of the *singly* qualified and *partially* educated practitioner has been put a stop to by the Medical Act 1886. Why should any practitioner propose to repeal that Act?

I am, Sir, yours, &c.,
Robert R. Rentoul.
Liverpool.

WHAT CONSTITUTES UNSOUNDNESS OF MIND?

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—You naving favoured me, a general practitioner, with inserting two letters on a subject about which I am so little cognisant, and having thus far confined myself to showing the treachery of phraseology, if loosely employed, as I demonstrated in "Climacteric Mania," I crave a little space to pursue the subject still further.

There can, I think, be no doubt that the question of insanity in its broadest acceptation casts one adrift upon a sea of speculative thought; indeed, almost enough to shake our confidence and uproot so-called civilisation itself. Quite recently I read a law case of disputed sanity, the medical witness being asked to define it, *i.e.*, Insanity, candidly admitted his inability. Surely no more serious compromise of medical evidence could exist, and on these grounds I ask to submit a few more suggestions on the definition thereof. Let us suppose, therefore, as in the above case, that the witness had attempted to define insanity as follows: "I mean by an insane person, one whose general conduct and ideas so far deviate from that section of the community amongst whom by nature he has been associated, as to render it necessary to deprive such person to a greater or less degree of freedom of action common to the other members of the same community." I fail to see how the bar, if you will pardon a slang expression, could have returned much change. I have said to "a greater or less degree" advisedly, because it might be necessary to deprive an insane person of his liberty to a very limited degree only. Thus: I once knew a shrewd lawyer, well-bred and excellent company, who moved in Society much like others, and unfortunately possessed a delusion in being the victim of some poisonous intent on the part of relatives and others. Society in its present state would resent, and, indeed, I could not myself, if asked, be any party to a certificate for his removal to an asylum. But supposing the delusion influenced his testamentary disposition, depriving his near-of-kin of natural and legitimate expectations, he must be deprived of his liberty to that lesser extent as to invalidate him as a testator.

With regard to the legal definitions of insanity, they appear to me vague and incoherent. In a text-book on Forensic Medicine (Husband) the law, if accurately interpreted, runs thus: "To excuse a man from punishment on the ground of insanity, it *must be distinctly proved*—the italics my own—that he was not capable of distinguishing right from wrong, and that he did not know at the time of committing the crime that the offence was against the laws of God and Nature." Now, Sir, I venture to state at a guess that the majority of insane who commit crime are aware that it is a breach of the laws of man; on the other hand no inconsiderable number who would be regarded by the best experts thoroughly sane have the slightest belief or feeling of moral responsibility. If, therefore, all sense or belief in moral responsibility be absent, as it frequently is amongst the sane, how can the law reasonably insist, upon proof of its absence as a *sine qua non* in insanity. Moreover, if we test moral responsibility in a purely logical or theoretical sense I feel bound to submit we are brought face to face with a most abstruse problem. Allow me an example. Suppose two persons resolve say to skate, but warned of the danger of the ice one, intrepid and fearless, ventures and drowns, the other, cautious and timid, refrains and escapes. Intuition tells us both are morally responsible, and, indeed, acting upon that supposition *to a degree* constitutes our sanity; but supposing further it be advanced that the intrepidity of the one and the timidity of the other depended upon their respective nervous organisations, over which they had no hand in organising, and hence that their *apparent* responsibility was not their real. For these reasons I contend a proper definition of insanity should not touch the question of moral responsibility, or, in other words, "The laws of God." In conclusion I thank you most heartily for your indulgence.

I am, Sir, yours, &c.,
Clement H. Sers.
Queen's Road, Peckham, S.E.,
May 4th, 1894.

The Mortality of Foreign Cities.

The annual death-rate per 1,000 in the principal foreign cities, according to the weekly returns communicated to the Registrar-General, is as follows:—Calcutta —, Bombay 34, Madras 30, Paris 23, Brussels —, Amsterdam 19, Rotterdam 27, The Hague 19, Copenhagen 19, Stockholm 17, Christiania 16, St. Petersburg 27, Moscow 34, Berlin 18, Hamburg 19, Dresden 23, Breslau 27, Munich 25, Vienna 25, Prague 34, Buda-Pesth 30, Trieste 33, Rome 21, Turin —, Venice 20, Cairo 49, Alexandria 40, New York 22, Brooklyn 20, Philadelphia 20, New Orleans 26.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Dr. M. G.—You would not be justified in making an examination of the girl without her formal consent, and this, if your suspicions are well founded, she is certain to refuse. Nor is this a case in which silence gives consent. It is safer to rely on the results of such an examination of the breasts, &c., as can be obtained, and in case of doubt to advise her being sent home for a while "under observation."

Sir Wm. Broadbent is thanked for his note.

Dr. J. H. B.—We will make the necessary inquiries and write you the result.

Meetings of Societies, Lectures, &c.

WEDNESDAY, MAY 9TH.

Hunterian Society.—At 8 p.m., Adjourned Discussion on Diphtheria. Dr. Washbourn: Early Diagnosis of Diphtheria and Bacterial Cultivation.—Dr. George Turner: Relation to Diseases of Lower Animals.—Mr. Shadwell: Mode of Spread. Dr. Thorne Thorne, Dr. Edward Seaton, and other speakers. Dr. Hingston Fox: Mortality during Thirty-five years past illustrated by Diagrams. Drs. Pitt and Goodall to reply.

Laryngological Society of London (20 Hanover Square).—At 5 p.m., Dr. Dundas Grant: Lupus of the Nose and Larynx.—Mr. R. Lake: A case in which one Lobe of the Thyroid has been Removed for Graves' Disease.—Dr. Felix Semon: (1) Two cases of Malignant Disease of Larynx treated by Thyrotomy and Radical Removal of the New Growths; (2) A case of Lupus of Pharynx and Larynx; (3) Sequel to a case of Obscure Pharyngeal Ulceration shown at the February Meeting.—Dr. Scanes Spicer: A case of Fixation of Left Vocal Cord.—Mr. W. R. H. Stewart: A case of Unilateral Laryngitis for Diagnosis.—Dr. Watson Williams: An Intra-laryngeal Syringe for Submucous Injections.

London Post-Graduate Course.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. Sidney Martin: Modes of Infection in Tuberculosis. Royal London Ophthalmic Hospital, Moorfields.—At 8 p.m., Mr. A. Q. Silcock: Choroidal Affections, with illustrative cases. Hospital for Skin Diseases, Blackfriars.—At 1 p.m., Dr. Payne: Psoriasis.

Metropolitan Hospital (Kingsland Road, N.E.).—At 5 p.m., Dr. Drysdale: Phthisis Pulmonalis, a Contagious and Hereditary Disease. (Post-graduate Lecture.)

THURSDAY, MAY 10TH.

British Gynæcological Society.—Adjourned Discussion on Dr. Routh's paper on the Conservative Treatment of Diseases of the Uterine Appendages.

London Post-Graduate Course.—Hospital for Sick Children, Great Ormond Street.—At 3 30 p.m., Dr. O. Sturges: Clinical Lecture. National Hospital for Paralysed, Bloomsbury.—At 2 p.m., Dr. Ormerod: Paraplegia. Central London Sick Asylum, Cleveland Street, W.—At 5.30 p.m., Mr. John Hopkins: Cases in the Wards.

North London Medical and Chirurgical Society (New Board Room, Great Northern Central Hospital, Holloway Road, N.).—At 9 p.m., Dr. Harry Campbell: The Treatment of Chronic Heart Disease.—Dr. Morison: The Practical Bearing of the Aspirative Forces in the Circulation.

Royal Institution.—At 3 p.m., Prof. Dewar: The Solid and Liquid States of Matter.

Royal Meteorological Society and the Sanitary Institute (Parkes Museum, Margaret Street, W.).—At 8.30 p.m., Mr. F. Gaster: Fog, Clouds, and Sunshine.

FRIDAY, MAY 11TH.

Clinical Society of London.—At 8 30 p.m., Mr. J. R. Lunn and Dr. C. E. Beevor: A case of Syringomyelia.—Dr. Churton: A case of Pancreatic Cyst with Diabetes; Incision of Cyst; Death a year afterwards; Atrophy of Pancreas.—Dr. Vivian Poore: A case of Enteric Fever occurring in a Diabetic subject.—Dr. Lee Dickinson: Hæmoglobinuria from Muscular Exertion.—Mr. Martin Randell (introduced by Dr. Rose Bradford): A case of Peliosis Rheumatica.

London Post-Graduate Course.—Hospital for Consumption, Brompton.—At 4 p.m., Dr. Sidney Martin: Cases of Phthisis.

Royal Institution.—At 9 p.m., Rev. S. Baring-Gould: English Folk Song.

SATURDAY, MAY 12TH.

London Post-Graduate Course.—Bethlem Hospital.—At 11 a.m., Dr. Hyslop: Acute Mania.

Vacancies.

British Institute of Medicine.—Assistant in the Bacteriological Department. Immediate applications to the Hon. Sec. (See advert.)

Cardiff Union.—Assistant Medical Officer. Salary £100 per annum, with rations, apartments, attendance, washing. Applications and testimonials to the Clerk by May 10th.

Chesterfield Hospital and Dispensary.—Junior House Surgeon and Dispenser. Salary £50 per annum, with board, apartments, &c. Applications and testimonials to the Secretary by May 17th.

Church Stretton Union.—Medical Officer and Public Vaccinator. Salary £10. Applications and testimonials to the Clerk not later than May 10th.

Derby County Asylum, Mickleover.—Locum Tenens. Salary £2 2s. weekly, with board, &c. Applications and testimonials to the Medical Superintendent.

Durham County Hospital.—House Surgeon. Salary £100 per annum, with board and lodging. Applications and testimonials to the Hon. Sec. by June 1st.

Fisherton Asylum.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing. Applications to Dr. Finch, Salisbury.

Kent County Asylum, Chartham, near Canterbury.—Junior Assistant Medical Officer (unmarried). Salary £125 per annum, with furnished apartments, board, and attendance. Applications and testimonials to the Clerk to the Committee of Visitors on or before May 14th.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Resident Medical Officer. Salary £60 per annum, with board, apartments, and washing. Applications and testimonials to the Secretary by May 15th.

Nottingham Borough Asylum.—Assistant Medical Officer (unmarried). Salary £100 per annum, with board, apartments, and washing. Applications and testimonials to the Medical Superintendent by 21st May.

Stoke-upon-Trent.—(1) Visiting Medical Officer of the Workhouse; (2) Resident Medical Officer of the Workhouse. Salary of the former at the rate of fifty guineas, and of the latter £120 per annum, with board, washing, and furnished apartments. Applications before May 11th.

York Dispensary.—Resident Medical Officer (unmarried). Salary £150 per annum, with furnished apartments, &c. Applications and testimonials to W. Draper, Esq., De Grey House, York, on or before May 15th.

Appointments

Cohen, G. A., Resident Medical Officer to the National Hospital for Diseases of the Heart, Soho, London, W.

Langlands, F. H., M.B., Ch.B.Melb., F.R.C.S.Eng., Demonstrator of Anatomy at the University, Melbourne, Victoria.

Lyle, H. W., M.R.C.S., L.R.C.P.Eng., House Surgeon to King's College Hospital.

Mackay, F. W., M.B., C.M.Edin., Resident Physician to the City Hospital, Edinburgh.

Master, G., L.R.C.P.Lond., M.R.C.S., House Surgeon to the Suffolk General Hospital.

Mitchell, A. B., M.B., B.Ch., B.A.O.Irel., Honorary Surgeon to the Ulster Hospital for Children and Women.

Mortimer, J. D., M.B., F.R.C.S., Medical Officer to the Earlswood Hospital for Infectious Diseases.

Morison, A., M.D., F.R.C.P.Ed., M.R.C.P., Physician to the St. Marylebone General Dispensary, London, W.

Nicholls, S. R., L.R.C.P.Lond., M.R.C.S., Medical Officer for the No. 1 Stratford Sanitary District of the West Ham Union.

Robinson, F., M.B.Vict., Ch.B., Resident Medical Officer of the City Hospital, Parkhill, Liverpool.

Seaton, D., M.B.Vict., House Surgeon to the Leeds General Infirmary.

Smith, F. M. G., L.R.C.P., L.M.Edin., M.R.C.S., Medical Officer for the No. 4 Sanitary District of the St. Albans Union.

Steward, E. S., M.R.C.S., L.R.C.P., House Physician to the Leeds General Infirmary.

Thomas, J. G., M.B., M.S.Edin., Medical Officer for the Penderyn Sanitary District of the Merthyr Tydfil Union.

Tindal, A. S., M.D., C.M.Glasg., Physician to the Tradeston Dispensary of Victoria Infirmary, Glasgow.

Todd, L. R., M.R.C.S., L.R.C.P., House Surgeon to the Leeds General Infirmary.

Turner, W., M.R.C.S., L.R.C.P.Eng., House Surgeon to King's College Hospital.

Wace, C., M.R.C.S., L.R.C.P., Assistant House Physician to King's College Hospital.

Walker, H. R., L.S.A., House Surgeon to King's College Hospital.

Walker, F., M.R.C.S., L.R.C.P., Resident Medical Officer to the Ida Hospital, Leeds.

Webb, J. C., B.A.Cantab., M.R.C.S., L.R.C.P.Eng., Assistant House Acoucheur to King's College Hospital.

Births.

Goddard.—May 1st, at Pentonville Road, N., the wife of Bertram Goddard, L.R.C.P.Lond., M.R.C.S., of a son.

Sturge.—May 4th, at Belmont Lodge, New Eltham, the wife of H. Havelock Sturge, M.R.C.S., of a son.

Marriages.

Watkins—Doleman.—April 30th, at St. Matthew's Church, Nottingham, Ernest R. Powell-Watkins, M.R.C.S., L.R.C.P.Ed., of Nottingham, to Margaret Agnes, second surviving daughter of Mr. John Doleman, of Musselburgh and Nottingham.

Deaths.

Baber.—May 4th, at 32 Cranley Gardens, South Kensington, John Baber, M.D., of Meopham and Brighton.

Laseron.—April 28th, at his residence, The Green, Tottenham, Michael M. A. H. Laseron, M.D., aged 74.

Lunan.—April 25th, at Blairgowrie, Perthshire, Robert Lunan, L.R.C.S.Edin., aged 81.

Park.—April 30th, at Milverton Lodge South, Leamington, Surgeon-Major Thomas Park, late Royal Artillery.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

VOL. CVIII. WEDNESDAY MAY 16, 1894. No. 20

Clinical Demonstrations.

By JONATHAN HUTCHINSON, F.R.S., LL.D.,

Ex-President of the Royal College of Surgeons, England,
Consulting Surgeon to the London Hospital.

MR. JONATHAN HUTCHINSON was "at home" on the afternoon of the 27th ult. for his usual demonstration of clinical cases at his Clinical Museum in Great Portland Street. These "afternoons," judging from the attendance of practitioners, are fast becoming very popular, a fact which is by no means surprising, considering the halo of attraction which environs all Mr. Hutchinson's work as a teacher. His facile manner in demonstrating a case, and of endowing it with interest, by drawing upon his illimitable stores of clinical knowledge are striking features of his wonderful capacity in this respect. Presumably it is not known yet to the profession in London that these demonstrations are perfectly free, that Mr. Hutchinson welcomes all practitioners who may wish to come, and that the meetings take place on Tuesdays until further notice, otherwise it could not fail to be the case that the rooms would soon be overcrowded.

Among the cases which came under notice on the 27th ult. was one of

PRURIGO.

The patient was an elderly man of 63. His whole skin was in a pruriginous condition, with scars in many places, and the case was described by Mr. Hutchinson as a typical one of prurigo. The man was evidently a "good scratcher." On inquiry the patient stated that the disease first troubled him when he was thirty years of age, and since then he had never been free from it. The irritation was always worse when he was warm in bed at nights, and was infrequently kept awake for three or four hours at a time scratching himself. The question of the duration of the disease was one of some importance. Mr. Hutchinson did not agree with Hebra's views on the matter, namely, that prurigo always began soon after birth and continued to the end of life. He (Mr Hutchinson) had never met with a case of the kind, neither in private nor hospital practice. He had sought for cases diligently but without result, and even in the hospitals in Vienna he could not find a patient whose history supported Hebra's description in this respect. The probability was, however, that the disease never began quite without some exciting cause. Among such causes might be enumerated, attacks of scabies, jaundice, or the presence of lice in persons whose skins were naturally irritable. As the result of one or other of these abnormal conditions scratching would follow, and then from this beginning the disease would continue and increase. There was one symptom, however, described by Hebra which was very constant in prurigo, and that was enlargement of the glands in the lower part of Scarpa's triangle. The characteristic features of these enlarged glands were that the latter were quite indolent, showed no tendency to increase, and no inclination to soften and break down. But experience proved, according to Mr. Hutchinson, that when enlargement of the glands was present an unfavourable prognosis of the case could only be given. [In the patient under notice this symptom was marked.] It was a fact that many things increased the itching in these cases, and notably bile in the blood, and where diabetes was present. With respect to treatment local remedies were only of use. Arsenic was powerless to effect any good. Strong solutions of tar, that is to say, the liquor carbonis detergens without any dilution, will be found to be of most value. Strict instructions, also, should be given as to diet. All fish should be forbidden, and anything which was found to cause irritation of the skin avoided. On the other hand, among other things, plenty of green vegetable could be allowed. The patient, in this case, whose occupation was that of a wood sawyer, denied ever having been troubled with pediculi, but admitted having had several attacks of gout, a fact which would tend, Mr. Hutchinson said, to increase the irritation.

The next case was one of

VARICES OF THE LEGS.

This patient was an old man of 75, both of whose legs showed a good deal of staining, with chronic œdema, and a number of small varices. The integument also was at one or two spots just beginning to ulcerate. In answer to the question whether he was accustomed to stand for many hours in the day the man replied in the negative, his occupation being that of a clerk, during which he sat at a desk. This patient also admitted a gouty history, and Mr. Hutchinson remarked that it was the part of all gouty inflammations to be attended with vascular enlargement. The most marked features of gouty inflammation of the skin were duskiness of hue, œdema, and venous turgescence. There were, however, many worse things than gout. Gout often was found associated with longevity. The teeth of gouty people were generally, also, very good, while the nails were sound and strong.

The next case was an interesting one of

PERFORATION OF THE NASAL SEPTUM.

The patient was a young man of about 27, with a clear ruddy complexion, in whom there was a perforation of the nasal septum, together with some necrosis of the alveolus above the canine tooth on the left side. It used formerly to be supposed that a perforated septum was always an indication of syphilis, but such a view was entirely erroneous, and in proof the patient under notice was a very interesting example. Some years ago both Sir James Paget and Mr. Hutchinson pointed out in papers contributed to the medical journals that perforation of the septum occurred in tuberculous patients whose history was absolutely negative in respect to any syphilitic infection. The perforation in the present case was such that Mr. Hutchinson was able to pass a bent probe through one nostril and cause it to project through the other. The patient denied having had syphilis, and there were undoubted signs of his having suffered from tuberculous lesions. In the first place there was a pucked scar on the cheek, just below the inferior and outer margin of the orbit, the result, in all probability, of a tuberculous periostitis with caries of the bone, followed by adhesion of the skin. Again the little finger of the right hand was merely represented by a stump, owing to exfoliation of the whole of the first phalanx. There was, moreover, thickening of the corresponding bone in the little finger of the left hand, and the patient stated that this finger recovered without any abscess forming, some years ago when his hands were affected. Over the middle of the metacarpal bone of the left thumb there was a deep cicatrised hole. All these lesions developed when the patient was about fifteen years of age. At that time he had been apprenticed to a saddler, and in the course of his trade he was required to hold between his knees a large contrivance, commonly seen in saddlers shops, for keeping the piece of work in position while the latter was being sewn. The result of the pressure applied by his knees was the development of a large abscess on the inner side of his right thigh, which, at the time, was opened, while on the left side in the corresponding situation a hard lump, freely movable, could now be felt, which was undoubtedly the calcified remains of an abscess. On inquiry a strong family history of tuberculosis on his mother side was elicited, a number of his maternal relations had died of phthisis. No lesion of the skin had developed in this case.

The last case was one of

MERCURIAL TEETH.

The patient, a young man of 23, came to show himself, whose teeth were typical of those which had suffered from the effects of the administration of mercury in early life. The enamel was defective, the teeth were thin and discoloured, and the first molars, as was usually the case, wholly carious, while the bicuspids were fairly good. On inquiry it was elicited that he had had convulsions in infancy, for which so-called soothing powders were given containing mercury. Associated with convulsions it was common to find lamellar cataracts, and examination showed that in this patient this lesion was present, though not to a degree which interfered much with vision. There was no reason for supposing that the administration of the mercury had anything to do with the development of the opacities in the lenses.

ON CASTRATION IN FEMALES: (a)

ITS FREQUENT INEXPEDIENCY AND THE SIGNAL ADVANTAGES OF CONSERVATIVE SURGERY IN THESE CASES.

By C. H. F. ROUTH, M.D., M.R.C.P.Lond.

(Concluded.)

MODES OF OPERATION ON THE ADNEXES.

II. CASES IN WHICH THE TREATMENT IS CARRIED ON THROUGH THE VAGINA OR RECTUM.

1. It is well to note first what is now admitted on all sides, but which is of immense importance, that disease of the annexes is merely an extension of disease by contiguity of surface from the vagina and uterus.

2. That in many cases of diseased tubes there is complete communication between the uterus and the tube. In Dr. Lewer's 100 post-mortem cases in 8 cases out of the 17 cases of disease of the adnexa, the dilated tubes freely communicated with the uterus, in 2 cases (where the fimbriæ of the tubes were occluded on both sides, there was communication with the uterus on one side but not on the other (Pathol. Card of Fall. tubes, "Obstet. Trans.," 1887, p. 220). Dentu describes two cases in which there was spontaneous evacuation of the tubal contents per uterus (Nouveaux, *Archives de Gynœcologie*, vol. 7, 1892, p. 127-8). Two more cases he mentioned in the Congress of Surgery n 1891.

3. It is also stated, by Dentuthat in most if not all cases of *hydrosalpinx* the opening with the uterus is patent. Indeed, the very symptoms of the disease, recurring from time to time, especially when the patient has caught cold, or as a sequence of endometritis, and when as generally believed the dropping of some of the secretion into the peritoneum, gives rise to slight peritonitis, is proof of this patency on the uterine side from whence came the recurring inflammation. Clearly, therefore, as in its earlier stages and even sometimes later, you cannot, unless you perform abdominal section, know whether it is a case of hydrosalpinx or pyosalpinx, the indication is to treat the case *per vias uterinas*, as if it were the former.

4. It is beyond doubt that in many cases where the abdomen has been opened and adhesions or portions of the annexes removed, nature has subsequently gone far to cause all, or very nearly all, morbid appearances to disappear. This has been proved not only by post-mortems of patients on whom laparotomy has been performed for disease of annexes, or adhesions have been separated; but also by those cases in which the abdomen has been opened a second time for some other disease, and in which on examination restoration to integrity in an adnex previously operated on, has been observed.

Lastly, it must also be borne in mind that an ovarian abscess, quite the size of a hen's egg, may become dormant. The more liquid parts are absorbed, and a substance not unlike that found in wens fills up the organ, and is otherwise harmless. Twice I have seen this. Once in a young lady who had abscess of the ovary. The pain and local symptoms entirely subsided. Later on in life she died of poisoned blood. The ovary was found at the post-mortem in this condition. In another case in which I performed ovariotomy, for a cyst on the right side, the ovary on the left side, about the size of a pigeon's egg, contained a similar cheesy substance. Several years before I had treated her for left salpingitis, and for years back it had given no trouble.

The treatment of many of these cases beginning through the uterus itself, has been practised by Doleris, Dentu, Mangin, Dr. Bell, of Glasgow, and more lately by Dr. Robert A. Murray. The last named gentleman's cases are fully detailed in the *Gynæcological Journal* for November 1893.

The plan of treatment adopted by all these gentlemen with some slight modifications may be generally described as follows: First, perfect rest is enjoined. Secondly, the inflamed adnex is treated by ordinary antiphlogistic measures, so often neglected by those affected with the "furor secandi." Blisters locally. Hot antiseptic injections, purging and allaying any feverish excitement. When this has been done, and the more active symptoms are overcome, then dilatation of the uterine cavity by sea tangles or sponge tents carefully asepticised can be safely carried out. The uterus by the second or third day is dilated sufficiently. It is then curetted thoroughly and plugged with iodoform gauze. Under this system experience has demonstrated that the inflammation of the adnexa disappears, and the patient enters into convalescence. It should be remarked that in these cases it is impossible, as the abdomen is not opened, to say whether these are cases of pyosalpinx, or salpingitis, but probably many of them are of the former class, 19 cases are so recorded by Dr. Doleris, and 25 by Mangin, in all but 2 of which recovery takes place. In several of the cases detailed, discharges of a purulent character passed *per vaginam*, and drainage had to be had recourse to. At any rate they prove that in ordinary cases of salpingitis chronic or acute, castration is not necessarily required.

The cases of Dr. Murray, which are given under the cases for gonorrhœal inflammation of the tubes, however are more striking still, and were all cases of pyosalpinx, and got well by precisely the same mode of treatment as the cases of Doleris and Mangin.

In a few of the cases of Doleris and Mangin, electricity was employed as an adjunct, but more with a view of diagnosing the extent of the inflammatory lesion, and whether acute or chronic.

(a) Paper read before the British Gynæcological Soc., April 19, 1894.

THE ELECTRICAL TREATMENT.

Of inflammation of annexes as a result of gonorrhœa. Some years back when in Paris, and through the kindness of Dr. Apostoli whilst following his klinik, I was surprised at the readiness with which this variety of disease was cured by electricity. The principle was to place one of his pads on the belly and a stiletto well guarded by non-conductors inferiorly, but the upper inch of which terminated by an envelope of charcoal, was placed within the cavity of the uterus. The electrode on the belly was positive, that in the uterus negative, and then for about ten minutes a continuous current of so many milliampères as did not give rise to much pain, was passed through the pelvis. Now these cases had all a genuine history of gonorrhœa. In these we had the characteristic urethritis, and the ovaries and tubes were painful and swollen. These cases all got well. I thought at first that the charcoal *in utero* might act as a counter-irritant. But I find that two other causes may be assigned. One that dilatation of the tube is induced by the electric current, and so allows the fluid to escape more readily *in utero*. This has been denied, and indeed, pronounced as a dangerous operation. Dr. Kehrer quoted by Mr. Alban Doran, in his paper read before the Medical Society on the Treatment of Chronic Disease of the Uterine Appendages ("Med. Soc. Trans., vol. iv, 239) has stated that it may if applied to the uterine cavity, cause rupture of a suppurating Fallopian sac. It is a pity that in such cases, the variety of current and its power, and which pole was placed *in utero* are not definitely stated, also whether it is a strong interrupted current or continuous one, either it is evident might produce this result, especially if the positive, but I am satisfied that the continuous negative current does produce dilatation of the uterine cavity. Even if scarcely admitting a quill it will soon allow two fingers to be introduced. The positive has the opposite effect as I have often verified. How also does it act in cases of stricture of the urethra in the male? This shows how necessary it is to be more precise in these objections. Dr. Prochownich has stated that even 40 milliampère currents cannot be borne in the female urethra, but then he does not say whether he refers to the positive or negative pole.

But a second reason has been given by Dr. Prochownich. Electricity is fatal to gonococci as he has often proved, even killing the germs, and the uterus can bear safely a current up to 120 milliampères. Mr. Doran, in reference to this statement, quoted in his paper, says "this statement sounds wild, yet it at least claims a definite action." This is a philosophical observation, and verifies the old proverb "Truth is stranger than fiction." This electrical action, however, receives confirmation, from the Webster process of purification of sewers by electricity. A strong electric current was passed through the sewage by means of iron electrodes. It is claimed that by this process, the organic constituents of sewage are not only split up by electric action and precipitated, but oxidised by the nascent oxygen and chloride oxides evolved. Tried at Salford it gave fairly satisfactory results. But this process has been much simplified by M. Hermite, of Havre, and examined on behalf of the British Institute of Preventive Medicine by Dr. Ruffer. Hermite's plan is to pass a current of electricity through sea water. This leads to ozone, free chlorine and various unknown oxygenated products of chlorine being set free; which possess a marked oxidising and bactericidal action. It not only kills these organisms, but destroys all odours, even the black sides of sewers became polished and clean when this sea water is passed into the sewers. It is clearly evident from this, that Apostoli's treatment of gonorrhœal salpingitis and ovaritis is based upon scientific foundation. It is manifest, therefore, in such cases, that even the electrophobists in our profession, should pause before they practise castration.

This conclusion in no way militates against the mode of treatment of gonorrhœal cases adopted by Dr. Robt. A. Murray, and recorded in our last quarter's journal, indeed, is rather confirmatory as effecting a cure without castration. He cures his cases by the measures before detailed, rest, antiphlogistics, dilatation, curettage, &c., but this plan appears simpler.

CASES TREATED ENTIRELY THROUGH THE UTERUS AND BY PUNCTURE OF THE PYOSALPINX THROUGH THE VAGINA OR RECTUM.

In the Association Journal (2, 1888, p. 828) a curious case of salpingitis and ovaritis is described by Schlesinger, of St. Petersburg. She was a multipara, æt. 42, ill after an abortion with a tumour in the right iliac fossa, operated by abdominal section by Dr. Seydel, on February 21, 1784. Particulars are fully given. Finding he could not remove it, he aspirated the tumour, drawing by suction with his mouth the purulent contents in the tube four times daily. A little fever followed for a week but in a fortnight the opening began to close and the patient recovered. Two years after this woman continued in perfect health.

Now here was a case which with our appliances could have been treated far better, a proper aspiration syringe in the present day applied, and without need of abdominal section at all.

I may say that starting with the certainty that in nearly all cases of salpingitis the disease originates with the uterus, if we attack that organ as we should any inflamed organ elsewhere, we can arrest the process of the disease, and this is the plan that I advocate. Perfect rest being insisted on.

1. Local blood letting either by scarifying the cervix, or cutting the os on both sides to promote some escape of blood, or in other cases 5 or 6 leeches applied to the cervix. In the case of virgins, if the hymen be very small, and not easily dilated, I apply leeches around the anus after the French mode, occasionally over the region of the adnexa.

But 2, I prefer instead of applying leeches over the locality of the adnexa, to apply a blister there, and as the hairs are apt to interfere with its close application, and I do not care to increase pain even in these parts temporarily, I use the liquid blister, two coatings, and then cover it over with medicated cotton. The blister will rise in about eight hours fully, and so soon as I have cut open the bullæ, the cotton is applied again, and in about three hours more bullæ have risen, which are again cut and the cotton applied a third time. the blistered portion may be dressed in the usual manner. One blister has thus done the work of three.

3. Using antiseptic measures freely, if I find that the tubes are relieved, the application of strong iodine or carbolic acid to the uterine cavity will often determine a cure.

4. If not, dilatation by sea tangles, carefully asepticised, is effected and then strong iodine applied. I do not usually find it necessary to use the iodoform gauze but have repeated the sea tangle tent covered with cotton dipped in carbolic acid.

5. Supposing, however, that the ovary or tube continued to enlarge, I should use hot douches in the vagina, hot poultices on the abdomen, keep the bowels well open by gentle purgatives and enemata, and treat any feverish symptoms as in ordinary cases of inflammation.

6. When I can detect fluctuation, I linger no longer but aspirate. If the matter is not offensive, I inject the cavity with iodine, and put no drainage tube in. If it is offensive, then I leave a drainage tube in, and

wash out the cavity daily with iodine until the discharge is very inconsiderable in quantity; when left to itself it generally heals.

A question here presents itself, where should the perforation be made, per vaginam, rectum, or abdomen? I have performed, and successfully, the operation of puncture in all these three situations. Wherever the swelling can be most readily felt, and where its coverings are thinnest. With antiseptic precautions all are safe, but as a rule, where it can be avoided, I think it is safer not to puncture through the abdomen.

Then, as to the choice of the vagina or rectum. The vagina is the cleanest medium, but it is also an open cavity, and we must not forget that each time a woman *ex*pires, the external air has a tendency to rush in, and so air may enter into the abscess opened, and become offensive, and require through the drainage tube a much longer use of the iodine lotion. The rectum is closed, and not so influenced by respiration, and for this reason, if the abscess be low down, it is advisable to puncture through that cavity, and this is especially the case with virgins. Care should be taken to use a drainage tube with a catch, so that once placed in position, it will remain *in statu quo*, and not come out.

Cases.

Feb. 14, 1880. Mrs. A., about 22. Right ovary inflamed, tender, afterwards left subsequently, at periods dysmenorrhœa. Treated by blistering and purging, afterwards tonics. Became pregnant. Confined October, 1883. Subsequently, about six weeks after change of residence, ovarian trouble returned. Punctured, a small quantity of pure healthy pus came away, recovery subsequently rapid.

Mrs. F. W. A., about 30. Mother of three children. Had suffered from menorrhagia in June, 1880. After trial of various remedies, uterus dilated, curetted, bringing away two mucous polypi, size of large beans. Touched cavity freely with iodine paint. Recovery complete. About three weeks subsequently, in July, laid down while very thinly clad on a very hot day close under an open window. Left ovarian inflammation followed, fever, &c. Finally, in about two weeks, punctured, washed out with iodine, giving exit to much fœtid pus in August. Some tenderness higher up followed, and some matter escaped. Recovery complete.

Mrs. McC., about 35. Married, several years without children, very neurotic, anæmic. Had had several attacks of endometritis. In 1880, had a good deal of dysmenorrhœa, and several attacks of ovarian pain, cystitis and indigestion. Finally, fever set in, and an abscess formed in the left ovary. This was opened with the aspirator, and about ¼ pint of very fœtid pus withdrawn, the cavity being well washed with iodine. Amelioration followed. but a relapse took place, and the abscess was again opened, fœtid pus again withdrawn, and the cavity washed out with iodine, but a drainage tube was kept in, and the cavity washed out daily. Perfect recovery followed. But she is still very neurotic, and liable to attacks of sickness and ovarian pain.

Mrs. M. Married some years, childless, not living with her husband, stating he had given her syphilis. Was residing in an hotel during the winter. Was seized with diarrhœa, a cold night, went down badly clothed to a water-closet, two stories below, caught a chill. A large abscess was in process of formation, left ovarian region. As soon as she could be conveniently removed to a private hospital after several days of complete rest, I punctured through the abdomen, where it was pointing with the aspirator; a quantity of air first made its exit, then about half a pint of very fœtid pus, iodine was injected, and a drainage tube kept in. Recovery followed. I heard of this patient about six months afterwards; she expressed herself as delicate, but much better. This illness occupied about two months. A quantity of solid effusion existing in Douglas space remained in process of absorption when last I saw her.

Mrs. R., seven years ill, perityphlitis, one child. Procidentia followed, then metritis, intense dysmenorrhœa producing almost insanity. Uterus inflamed, os almost closed. Came under my care February, 1890. Great tenderness of uterus, liver, and annexes, specially left side. Perfect rest, anodynes, purgatives, counter-irritation. In August, a buckle pessary introduced. Great relief to all symptoms. The buckle pessary was kept in till March, 1891, when it was removed. She missed it greatly, and was rampant to have it replaced. On examination in June, 1891, found metritis present, left ovary again enlarged and tender, and liver large. Rest, blisters, and counter-irritation reduced this state, and she left comparatively well. All enlargement of ovary had disappeared, but there was dysmenorrhœa present, which, however, was completely relieved by a Cross mixture. This case was very trying, the patient being very much spoilt and neurotic, and the fever extreme, and intestines from the first more or less matted together.

Miss McC., unmarried, a short very thin, delicate woman, consulted me for symptoms of dysmenorrhœa. Pain in both ovarian regions, the left originally the most painful, but now the right. There was the usual symptoms co-existing of endometritis, leucorrhœa, &c. On examination, the left ovary was distinctly enlarged about the size of a large pigeon's egg, but scarcely tender, No fluctuation in it. The right ovary felt as large as a turkey's egg, and was very tender, quite fixed to surrounding parts, but with a distinct indication of fluctuation. The question was, should I aspirate or perform abdominal section? In consultation with a distinguished abdominal surgeon, he was strongly in favour of opening the abdomen. I did so with the usual precautions. I found the left ovary about the size of a pigeon's egg, hard, but without any signs of inflammation. It had contained pus, I thought, but the watery particles having been absorbed, it was almost solid. Not so the right ovary. This was very much of the shape of one of Barnes' largest bags, matted and adherent to the surrounding tissues, and the covering in several places as thin as paper. I declared my inability to remove this entirely and wished to perforate and wash out the sac. My surgeon friend thought he could do it, and with my permission attempted to do so, but failed, bursting the sac, and letting out a very putrid pus. We removed the remains of the sac, sponged the matted intestines as well as we could, but the case died in three or four days from septicæmia, spite all we could do for our poor patient. Now, I have very little doubt that had I aspirated this case, I should have given my patient a better chance of life. The putrid contents of the ovarian sac were not more putrid, nor was the sac larger than other cases, where I have aspirated and saved my patient's life.

March, 1891. B. R., æt. 40, married fifteen years. Nullipara, catamenia, four to five weeks interval, scanty. Has had a stationary fibroid of uterus for ten years, reaching umbilicus.

Present illness.—Was chilled by up-draught in w.c. during period, followed next day by rigor, pelvic and general pains. Temperature for first few days between 100° and 102°. On 7th day, temperature rose to 105°, and for next two weeks varied between 104° and 104·6°. Pelvic examination showed lower zone of uterus fixed by hard phlegmon in sub-peritoneal cellular tissue, being especially marked on both sides of vagina, reaching lowest on right.

Aspirated deeply behind and to right of cervix, and ℥vj most offensive brown pus drawn off. Cavity washed out with iodised water. Temperature remained high for some days after an initial drop, and then slowly subsided to normal in fifth week. The same night that the aspirator was used, an adjacent abscess containing inodorous pus opened into bladder, but after twenty-four hours no pus passed per urethra. Patient convalesced slowly but satisfactorily. Pelvis now normal.

S. M. July 15, 1892. Æt. 38. Married, one child eighteen years ago. Had a rigor after last "period," with right abdominal pain. Temperature 101° to 103°. Examination. Cystocele, uterus prolapsed, fixed and pushed forward by tense bulging, elastic mass in Douglas pouch, and behind right broad ligament.

July 16. Aspirated *per vaginam.* ℥iij fœtid pus drawn off. Cavity washed out with iodised water. Exudation gradually cleared up, and temperature fell gradually, being 99° to 101° in first week, 98° to 100° during second, and normal during third. Discharged convalescent, and uterus mobile.

I could add other cases, but these, I trust, will suffice to prove the advantage of aspiration as a method of cure.

Conclusions.

1. The ovary, besides being concerned in ovulation, secretes especially, but in conjunction with other glands, a peculiar principle, spermin, which being reabsorbed into the blood, is most useful in the nutritive oxygenating and recuperative power to maintain the well-being of a female, and the want of which leads to bodily and mental debility. (Part No. 1.)
2. The complete castration of females leads to forced sterility, and in many cases to the induction of an earlier menopause and premature old age, and frequently to decay and perversion of mind. Partial castration produces similar effects, but to a minor degree. (Part No. 2.)
3. The mortality of cases of diseased adnexa when left to themselves varies from nil to 4 per cent.
4. But the mortality of cases operated on by abdominal section varies from 2·5 per cent. to 12·1 per cent. (Part No. 2.)
5. Complete castration has been practised too frequently and often unnecessarily.
6. Preceded by abdominal section, the modes of operating more conservatively by *partial* castration, *i.e.*, by resection of tubes, or tubes and ovaries combined, and by ignipuncture of cysts in the latter, gave much more satisfactory results and with less mortality even in cases of pyosalpinx and with no impairment of motherhood and power of child-bearing. (Part No. 4.)
7. The mode of treating diseased appendages *per vaginam* or rectum without abdominal section on the uterus itself, by electricity in cases of gonorrhœal pyosalpinx, and by puncture with the aspirator offers the greatest advantages, the mortality being almost nil, the recoveries durable, and the motherhood left intact.

◆

PAY-PATIENTS AND OUT-PATIENTS IN HOSPITALS. (a)

By H. C. TWEEDY, M.D. Dubl., F.R.C.P.I., Diplomate in State Medicine, Trin. Coll. Dubl.,

Physician to Madam Steevens' Hospital.

Dublin is justly proud of her hospitals. From the year of grace 1720, when the first general hospital was founded in the city by Madam Steevens, of happy memory, down to the present time, the work done in them has been of incalculable service to our less fortunate fellow-countrymen, and at no period of their existence have they reached a higher level of efficiency than is the case to-day. It is therefore with regret that we observe signs, slight signs, it is true, but not the less requiring our vigilance, that our hospitals are in danger of being utilised by the general public in a manner never contemplated by their pious founders. This is manifest if we consider—1st, the class of patients seeking admission to the pay-wards; 2nd, the class of patients frequenting the hospital dispensaries.

Let us take first the question of pay-wards. These were originally established to meet the needs of such persons as clerks upon small salaries, ladies in reduced circumstances and others unable to pay for proper nursing, not to speak of doctors' fees, but gradually a privilege intended for such as these, is being usurped by those much better off as regards worldly goods.

Whether private patients should be admitted at all into a general hospital is a matter open to discussion, but when persons in good circumstances come into a hospital as private patients, at a nominal charge, the responsibility becomes a very grave one for those who permit such a flagrant abuse of a charity.

And what does the hospital gain by such cases? Little or nothing. The cost of an ordinary patient *per diem* is 3s. 9d., if we include maintenance, establishment, and management. Few patients give more than one guinea per week, so that in the majority of instances the hospital loses at least 5s. 3d. per week.

But what of the doctors? The position of physician or surgeon to a hospital is, in most cases, an honorary one. The staff receive their share of the students' fees, and nothing more, save the privilege of using the ordinary patients as teaching material. Pay-patients, however, are not available for such a purpose; this would be highly resented by them or their friends; nor can the doctor receive any remuneration from them. It is a matter of honour with him not to take fees from hospital patients, but were he detected doing so, his hospital would, in accordance with a rule of the Hospital Sunday Fund, receive no grant from that body. If the pay-patients are to be taken into our hospitals at all, their circumstances should be rigidly inquired into, and none received save those absolutely unable to pay for, in their own homes, the advice and the nursing that they need. But after all, why should a charitable institution be burdened with this class of patient? Let us hope that we may see here before long special institutions that would meet their requirements. There is a growing need for private hospitals established say by limited liability companies, such hospitals should in their construction and management meet all the requirements of modern science, and should contain first, second, and third class accommodation, according to the rate of payment, all patients having an equal right to the services of a President medical officer, and should they require further advice, being at liberty to call in any doctors they pleased *at their own expense.*

To turn now to the question of extern patients. It will first be necessary to review briefly the provisions existing at present for the outdoor medical relief of the poor. If we take the large district comprised within North and South Dublin and its suburbs, from which the out-patients to the Dublin hospitals chiefly come, we find, according to the census of 1891, a population of 356,240 persons. For this population the Poor Law provides 27 dispensaries, 30 medical officers, and 11 apothecaries, who, according to the last report of the Local Government Board, attended 100,216 persons in one year.

Then we have 10 general hospitals and 14 special hospitals, all with out-patient departments attached to them.

Now the out-patients of a hospital may be classified under three headings: 1. Accidents treated as out-patients. 2. Midwifery cases treated as out-patients. 3. Cases attending the dispensaries of the hospitals.

Of cases included under the first two headings accurate registers are kept, so that their numbers can be relied upon. The returns of the Dublin hospitals for the past year are: Accidents (extern), 30,695; midwifery cases, 4,574—total, 35,269.

(a) Read before the State Medicine Section of the Royal Academy of Medicine, April 20th, 1894.

The dispensary cases amounted to the enormous total of 218,475. These figures cannot, of course, mean individuals, but must include the entire *number of attendances* of each patient; but assuming that each patient attends the dispensary six times—if we divide 218,475 by 6 we get 36,412. This number added to the accidents and midwifery cases before mentioned, gives a total of 71,591, which is probably very near the mark, and this last number added to the total number of patients (100,216) attending the Poor-law dispensaries, gives a total of 171,807 persons, or 482 to the 1,000 of the entire population of the district, rich and poor receiving gratuitous medical relief exclusive of those who are admitted intern patients to the various hospitals.

It is difficult to estimate the number of those who might fairly be considered entitled to such relief; but if we look in the returns of the Registrar-General for the Census of 1891 we find a classification which may help us. House accommodation is divided into four classes. The fourth class comprises the very poor living in crowded tenement houses. This class contains in round numbers about 100,000 persons in Dublin and its suburbs, undoubted objects of charity, and closely corresponding to the Poor-law returns just mentioned.

Those occupying third-class accommodation in the better sort of tenement houses consist chiefly of artisans, most of whom are in sick clubs or benefit societies, and cannot be regarded as paupers. At the same time, they might fairly be permitted to avail themselves of the advantages offered in our hospital dispensaries, were they prepared to pay a small sum, sufficient to prevent the charity being at a loss by them. And this, as a matter of fact, is the class that avails itself most largely of the extern departments of the Dublin hospitals.

The evils of this indiscriminate charity are obvious:—1st. Direct pecuniary loss to the hospitals. It has been estimated that the cost of each out-patient at a hospital is 1s. 6d., and when this sum has to be multiplied by thousands, it becomes a serious item in the annual expenditure. Let us illustrate this, assuming the approximate number of 100,000 persons occupying fourth-class house accommodation to be a fair estimate of the absolutely poor. If we subtract this number from the total of those receiving external medical aid from the Poor-law and the Dublin hospitals combined, viz., 171,804, we have remaining over 71,807. If we take again from this number the 11,807, assuming that these persons pay something at the few hospital dispensaries that do make a small charge, we have still in round numbers 60,000 free patients remaining, who, at the rate of 1s. 6d. per head, cost the Dublin hospitals £4,500 per annum.

The second evil of this indiscriminate charity is the injustice that is done to doctors and students. Our hospitals are essentially educational institutions; but teaching becomes impossible if the limited time at the doctor's disposal be taken up with a crowd of trivial cases, which form the bulk of those attending our dispensaries, and the work has to be rushed through in a perfunctory and unsatisfactory manner.

Again, an injustice is done to the benevolent public, who are paying twice over for the medical relief of the poor, first through the rates, by which the Poor-law dispensaries are supported, and again in subscriptions to hospitals for doing unnecessary and unprofitable work for which ample provision has been made elsewhere.

This wretched system must also have a demoralising effect upon the recipients of such charitable relief, nor can it be remedied till an accurate register be kept of the name, address, and occupation of each out-patient in every general hospital, to be followed up when necessary by a rigid investigation into the circumstances of all doubtful cases, and further, all save the very poor should pay a small sum to defray the cost of medicine, &c. It should not be possible for a lady to attend as an out-patient for several months the dispensary of a hospital, only to be accidentally detected by a student, who recognised in the hospital patient his hostess at a tennis party the previous week. It would be easy to multiply instances of this kind, but it is needless to do so. The facts are notorious, they exist in every large city throughout the United Kingdom, and this being so, surely all right-minded people will join in reprobating the monstrous wrong that is done, by the abuses I have mentioned, to the members of an overworked and, as a rule, underpaid profession, in occupying their time and talents upon objects undeserving of their charity, and also the injustice of diverting the contributions of the charitable and benevolent from their legitimate channels to the encouragement of a shameless and fraudulent abuse of hospital charities on the part of the well-to-do, and to the countenancing of a chronic and unnecessary haunting of hospital dispensaries by the idle or hypochondriacal poor.

◆

Selected Prescriptions and Therapeutic Notes.

132.—Useful in Fissure of the Anus:—

℞ Ext. conii, ʒij;
Ol. ricini, ʒiij;
Ung. lanolini, q.s. ad ℥ij.

M. Smear a small quantity over the parts five minutes before a motion is expected, and again after it has taken place. By this means spasm of the sphincter is relieved.—CRIPPS.

133.—For Hæmorrhoids:—

℞ Chrysarobin, gr. xiv;
Iodoformi, gr. v;
Ext. belladonnæ, gr. x;
Vaselini, ʒss.

M. This is to be applied as an antiseptic and a soothing ointment.—KOSOBUDSKI.

134.—Liniment for Neuralgia:—

℞ Chloroformi, ʒvj;
Ætheris sulph., ℥j;
Sp. camphoræ, ℥iij;
Tinct. opii, ʒiss.

M. Soak a small piece of flannel in the liniment, and apply over the painful part.

135.—Useful as a Prophylactic against Tonsillitis:—

℞ Ol. menthæ pip., ♏viij;
Acid. carbolici, ℥j;
Sp. vini rectificati, ʒij.

M. Ten drops to be added to a cup of warm water and this solution used as a gargle night and morning. —ROBERTSON.

136.—Useful in Hæmoptysis:—

℞ Quiniæ sulph., gr. lx;
Ext. secalis cornut., gr. xxx;
Acidi tartar., q.s.

M. Make forty pills. Two to be taken twice or thrice a day.—EKLUND.

◆

APPLICATIONS are invited from candidates for the Holt Chair of Pathology, and for the Derby Chair of Anatomy in the Victoria University, Liverpool. The endowment in each case is £375 per annum, together with a share of students' fees.

Transactions of Societies.

CLINICAL SOCIETY OF LONDON.

Meeting held Friday, May 11th.

The President, Mr. **Hulke**, in the Chair.

A CASE OF SYRINGO-MYELIA.

Dr. Beevor and Mr. J. R. **Lunn** gave the subsequent history of a case which they had shown in 1883 as a peculiar deformity of the hands and shoulders (Vols. xvi. and xvii. Transactions), and a special committee appointed to inquire into the case came to the conclusion that the various lesions were due to a central nervous affection akin to Charcot's disease. The patient remained under Mr. Lunn's care until March, 1893, when he died. In June, 1885, it was noticed that all the muscles of the arms and forearms reacted to Faradic and galvanic stimuli, though there was apparent wasting of the muscles on the flexor surfaces of the forearms traceable to the disease. The muscles of the right thumb did not respond to the Faradic current; those of the left did, however, as did all the internal muscles. The reactions of the muscles of the lower extremities were normal. There was no disturbance of sensation, but occasional fibrillar twitchings were observed. In 1888 the muscles of the legs and right foot were not at all wasted, but the third phalanx of each of the four toes of the right foot appeared to be dislocated on the heads of the metatarsal bones, producing a claw-shaped position as in the hands. The nails were much wasted, and disclosed atrophic conditions similar to those of the nails of the right hand. The left foot appeared normal except in respect of the toe-nails, which were beginning to waste. No nerve symptoms were apparent, and the patient's general health was good. In November, 1889, he began to suffer from girding pains and attacks of nausea. In January, 1891, he had several attacks of pemphigus on the dorsal and palmar surfaces of the hands, generally preceded by slight rises of temperature. In October, 1891, it was noticed that the wasting of the right finger-nails had increased, accompanied apparently by wasting and shortening of the terminal phalanges. No fresh changes took place except that the patellar reflexes increased, with ankle clonus, on the right side. While tactile sensibility was quite normal, sensibility to heat, cold, and pain was much impaired, and was almost absent over a considerable area of the arms, head, and chest. In the lower extremities slight spastic paralysis was remarked. Sensation of the lower limbs was unaffected, though there was a certain degree of ataxic gait and of unsteadiness on standing with the eyes closed and the feet together. On March 5, 1893, the patient had a fainting fit of short duration, and the next morning he had a difficulty in speaking. His tongue protruded towards the right side, and the lower half of his face seemed paralysed. The right arm and leg were slightly weak, and the head was turned a little to the left side. Although he appeared to understand what was said to him, and to want to reply, he was unable to do so, his power of articulation being confined to simple words such as "yes," "no," "one," "two," &c. The knee jerks were much increased on both sides, and the plantar reflexes slightly so. There was no ankle clonus. On March 7 the patient had considerable difficulty in swallowing, his pupils remained dilated, but acted to light. The legs seemed to be in a state of extensor spasm, and could be flexed only with difficulty. On March 10 he lost the power of the right arm and leg, and ultimately became comatose, and died on March 12.

Post-mortem: Old dislocations of both wrists, left shoulder, right thumb, and outer end of right clavicle were found. There were bullæ on several fingers; some finger-nails were wasted, others absent. There was hypostatic pneumonia. The right lobe of the cerebellum was smaller than the left. The lateral ventricles of the cerebrum were dilated. The left middle cerebral artery was thrombosed, and the cortex to which it went was softened. The central canal of the spinal cord was dilated in the cervical and upper regions. The dislocated joints were typical examples of osteoarthritis, and were so described by Mr. Targett, who had examined them.

Dr. **Beevor**, who had examined the spinal cord, reported that the case presented two groups of phenomena; wasting of muscles in arms and shoulders, especially affecting the intrinsic muscles of the hands, and sensory symptoms, with impaired sensibility, together with trophic changes, chiefly in the joints, nails, and skin. Dilatation of the central canal of the cord destroyed the ganglion cells in the anterior cornu, thus producing trophic changes, and consequent deformities, especially in the arms.

Dr. **Ormerod** said that, as regards this particular case, little remained to be said, save to compliment Mr. Lunn and Dr. Beevor on their complete and accurate report of a case which they had watched through so many years. He himself had only come across syringo-myelia post-mortem in two cases; the one a lunatic who presented no clinical symptoms, the other, a boy who presented the general symptoms of cerebral tumour complicated by an acute paraplegia. There was found post-mortem dilatation of the cerebral ventricles and of the central canal of the cord, but the Sylvian aqueduct was not dilated. Clinical examples of the disease were now accumulating; he had recently had two cases under his own observation. All cases of chronic muscular atrophy affecting the hands (particularly if associated with a spastic or ataxic condition of the legs) should be examined to see whether they presented the peculiar sensory symptoms characteristic of syringo-myelia.

Dr. F. **Taylor** also made some remarks.

Dr. S. **Coupland** referred to a case brought before the society in 1872 by the late Dr. Greenhow. The case was regarded as one of progressive muscular atrophy, but the cord showed a remarkable dilatation of the central canal. In the light of subsequent knowledge, this case might perhaps be considered one of syringo-myelia, to which the amyatrophy was secondary.

TYPHOID FEVER IN A DIABETIC PATIENT.

Dr. **Poore** related the case of a man, æt. 35, who was admitted to University College Hospital on October 5th, suffering from diabetes of moderate intensity. He remained under observation for 114 days. On November 16th, while under observation, he developed enteric fever, which lasted six weeks. The attack of fever was without diarrhœa or other serious complication, and might almost be regarded as a case of simple continued fever. An opportunity was thus afforded for observing the effect of the febrile condition on the urinary excreta. During the first week of his stay in the hospital, during which the patient was on the ordinary full diet, but was taking opium by the mouth, the urine for the week amounted to 1,218 fluid ounces, and contained 7,900 grains of urea, and 22,218 grains of sugar. During the next five weeks the patient remained in his normal diabetic condition, and was put on a rigid diabetic diet. For these five weeks, weekly average of urine was 673 fluid ounces, containing 6,118 grains of urea, and 3,781 grains of sugar. Then followed the period of fever, which lasted six weeks, and during this period (the average temperature for the whole period being 2·2° F. above the normal), the weekly average of urine was 491 ounces, containing 4,263 grains of urea and 1,214 grains of sugar. The febrile period was followed by a fortnight during which the temperature was subnormal, and it was found that the weekly average of urine was 644 ounces, containing 3,577 grains of urea, and 989 grains of sugar. During the last fortnight of his stay in hospital, during which the temperature was normal, the weekly average of urine was 537 ounces, containing 6,105 grains of urea, and 7,511 grains of sugar. These figures show that, although the urinary excreta were diminished during the fever, the period of their greatest diminution was that of subnormal temperature which followed the fever. Complete disappearance of sugar from the urine occurred on the fifth, sixth, and seventh days after complete cessation of the fever, when the patient's temperature averaged 97° F. On these three days the urine amounted to 294 ounces, and contained 1,088 grains of urea, *and no sugar.* The numbers seem to show that the greatest freedom from glycosuria occurred at a time when the needs of the body were great, and the patient was rapidly increasing in weight to replace the 24 pounds which he had lost during his six weeks of fever. He called attention to the existence of a certain parallelism in this case between the output of sugar and pulse-respiration ratio. As the value of R/R declined, so did the output of sugar. One might from this assume that as the output of carbon by the lungs increased, the output of carbon by the urine diminished. It occurred to him that the condition of the parotid gland in diabetes had, perhaps, not received sufficient attention either at the bedside or in the post-mortem room.

Mr. **Eastes** remarked that the work of subnormal temperature and absence of glycosuria in January last was that in which the external temperature was abnormally low. He inquired if Dr. Poore thought this might in any degree have accounted for the temporary improved condition of the patient.

Dr. **Coupland** believed that when a diabetic had typhoid fever the temperature generally had a low range.

Dr. S. **Phillips** narrated, in reference to one remark by the author, particulars of a case of acute glycosuria in St. Mary's Hospital, in which the patient a week before death had acute parotitis first on one side and then on the other.

Dr. **Poore**, in reply, hardly thought the external temperature could have had anything to do with the patient's condition in January last, as the temperature of the ward was kept up by artificial means, and the patient was in bed all the while. The temperatures given on the tables appended to the case were the averages of each week, and he observed that the average temperature of the fourth week of the illness which was 100·8 F. was undoubtedly high when it was remembered that it was the average for the week.

HÆMOGLOBINURIA FROM MUSCULAR EXERTION.

Dr. **Lee Dickinson** brought forward three instances of transient hæmoglobinuria from muscular exertion without serious symptoms. The subjects were healthy young men. In two of the cases the cause was a foot race of three miles and one mile undertaken in an untrained condition. In the third the attack supervened after a game of lawn tennis. He pointed out that instances were on record in which hæmoglobinuria had occurred repeatedly in the same subject from the strain of military or ordinary walking. Such cases he suggested were probably allied to "functional albuminuria" and associated with a condition of abnormal delicacy of the red corpuscles. In these cases, however, the blood was healthy, but the corpuscles were destroyed by some product of the unusual muscular exercise, probably carbonic acid. The symptoms seemed to indicate that the muscular power was out of proportion to the bodily condition.

A CASE OF PELIOSIS RHEUMATICA.

Mr. **Martin Randell** read notes of the case of a married woman, æt. 41, who for some years had suffered from dyspepsia and diarrhœa. She had been much addicted to alcohol. There was no history of rheumatism, acute or chronic. On September 2nd, 1893 she was taken ill with pain and swelling of the joints accompanied by a rash consisting of papules, some pale, most of them hæmorrhagic, varying in size from a split pea to a five-shilling piece. The temperature was about 100° F. Severe diarrhœa and vomiting set in a week later, the motions containing much altered blood, but the vomit was free from blood throughout. The rash continued till death, the old patches fading away and others taking their place. There was œdema, especially of the hands at times, confined, however, to the region of the affected joints. About a fortnight after the commencement, some of the papules sloughed, leaving foul ulcers. She died on September 21st after three weeks' illness. The urine contained a microscopic amount of blood. Post-mortem petechiæ were found on the serous membranes. The lungs were healthy and there was no sign of endocarditis. The intestines showed many ulcers, commencing in the duodenum and extending to the end of the ileum, but not to the large intestine. The liver, which was markedly fatty, weighed 103 ounces. The kidneys were normal.

Dr. **Rose Bradford** said the case was not one of erythema nodosum, the papules being found only in the neighbourhood of the joints. Neither was it one of ordinary acute rheumatism, there was no former history of rheumatism; very little swelling and not much pain of the joints. Neither was it one of syphilis; no history of syphilis could be elicited. There were, however, all the symptoms of peliosis rheumatica, except submucous hæmorrhage; but, possibly the gastric and intestinal ulcerations were due to submucous hæmorrhage and subsequent sloughing of the undermined mucous membrane.

◆

THE OPHTHALMOLOGICAL SOCIETY OF GREAT BRITAIN.

Meeting held Thursday, May 3rd.

Dr. **Argyll Robertson**, President, in the chair.

CYST OF IRIS.

Mr. **Mackinlay** showed a child, æt. 6, with a cyst of the iris, as to the nature of which he asked for suggestions. There was no history of injury. It is just possible it was a cysticercus. He proposed to do excision with an iridectomy. It had grown 2 mm. during the last six weeks.

Mr. **Hulke** pointed out that though these cysts were often the sequel of injury their relationship was open to question. In the majority of instances in which they followed injury they could not possibly have that origin. They did not look like growths inwards of squamous epithelium, for they were lined by a single layer of delicate tesselated epithelium.

Mr. **Henry Power** could only recollect having seen two cases of cysticercus of the eye in all his experience.

Mr. **Lawford** asked if there was any history of iritis, calling attention to the fact that it was shown some time ago by microscopical examination that these cysts were generally due to blocking and distension of the crypts of the iris. The surface aperture of these crypts was very narrow, and a very small amount of thickening would be sufficient to close them. This is a reasonable explanation of cysts which formed independently of any penetrating wound.

Mr. **Juler** said he had shown a similar case some months ago in a baby in whom an injury was out of the question. He excised it with a small iridectomy and the case did well.

Mr. **Hill Griffith** had seen a baby, six weeks of age, operated on for such a cyst the other day. In withdrawing the cyst it was accidentally ruptured, but a good recovery followed.

The **President** said all the cases of the kind he had seen had been traumatic, but the procedure in any case must be the same. Removal of the cyst had always effected a cure.

Mr. **Mackinlay**, in reply, said the only history of illness was an attack of influenza, but the eye after that attack was red and inflamed, and this supported Mr. Lawford's hypothesis.

CASE OF DOUBLE OPTIC NEURITIS FROM CARIES OF SPHENOIDAL CELLS AND INTRA-CRANIAL ABSCESS.

Dr. **Sandford** (Cork).—A man was admitted to the Cork District Asylum on April 19th, and died January 8th, 1894, æt. 78. Towards the end of 1891 his sight suddenly became impaired, and was subsequently totally lost. His case was one of double optic neuritis, and post-neuritic atrophy. He never complained of pain. He never had any symptoms of paralysis whatever, and had perfect control both over bladder and rectum. Two months before his death some proptosis of the left eye was noticed, and this increased for some days. Subsequently, a swelling about the size of a pigeon's egg was observed just above the arch of the zygoma. No operation was undertaken on account of the patient's age and feeble condition. After a time both proptosis and tumour ceased to increase. His temperature was subnormal throughout. On removing the skullcap the dura was found unusually adherent, the pia was slightly thickened and opaque. The convolutions were wasted, and the sac deep and gaping. On raising the frontal lobe they found a large tumour, apparently subdural, extending from the middle line to the left in various directions.

THREE CASES OF TUBERCLE OF THE IRIS.

Dr. **Sandford**.—Living in a district where tubercular affections are extremely common, he said it had always been a matter of surprise to him how small a proportion of eye affections one met with in which a directly tubercular origin could be proved, either in connection with tuberculosis of other organs or primarily in the eyeball, although he had long been convinced that many cases of iritis, keratocyclitis, and episcleritis were of an essentially tubercular character. He read notes of three illustrative cases:—

Case 1.—J. K., æt. 16, the only son of a mother who died of phthisis, came to him with iritis of the left eye of a few days standing. He had been suffering from a cold for a fortnight. A few days later he noticed several minute yellowish nodules on the iris, and at the same time there was evidence of fresh tubercular mischief in the apex of the right lung. After a few months of careful treatment, constitutional and local, the eye and lung symptoms subsided synchronously, the iritic granules disappearing by absorption. The pain and photophobia were insignificant.

Case 2.—A young woman, æt. 19 (mother's family phthisical, no history of syphilis), consulted him for eye trouble of a month's standing. The left eyeball appeared to be swollen and tension was increased. Several elevated yellowish nodules appeared in the ciliary region, invading the corneal substance. The iris was thickened, discoloured, and showed two small yellow nodules. The patient had had a considerable cavity for some years at the apex of the right lung, and there was an obvious recrudescence of tuberculous activity. After six months treatment the eye and lung troubles subsided simultaneously, and at present the only evidence of the eye affection were several cloudy spots in the cornea, marking the sites of the recent deposits.

Case 3.—M. C., æt. 5, was admitted on Jan. 28, 1886, suffering from iritis of a fortnight's standing. The child had an exceedingly tubercular appearance, and the mother's family was phthisical. The iris was thickened, dusky, and discoloured. A large yellow nodule projected from the iris into the anterior chamber, on the nasal side, and apparently involved its whole thickness, extending from the circumference half way to the pupillary margin. There was, however, little pain. V= fingers at two feet. As, after a fortnight, the tumour was increasing with alarming rapidity, the eyeball was excised, and, under anti-tubercular treatment, the child steadily improved in health. He handed round a tranverse section of the globe, showing the tumour involving the iris and projecting into the anterior chamber, blocking the iritis angle. Microscopical examination showed tubercular infiltration of the iris, ciliary region, suspensory ligament, and, possibly, the lens. At the time of the operation the child appeared free from tubercular deposits elsewhere. She had now been under observation for eight years, and though fragile-looking, had remained in fairly good health. He called attention to the absolutely simultaneous accession and subsidence of the eye and lung troubles in the first two cases. In one of them, at any rate, there appeared to have been a prætubercular catarrhal condition similar to that met with in analogous conditions of the larynx. Case 3 was one of primary tuberculosis of the iris, and possibly the prompt excision of the eyeball prevented further extension. He had found great benefit from painting the whole of the surface of the upper lid and brow with a varnish composed of equal quantities of iodine, mastich, and rectified spirit, especially in cases in which the pain and photophobia were severe.

Mr. Johnson Taylor said that it was necessary to distinguish between primary and secondary tuberculosis of the iris. In the former he recommended excision, but the secondary cases should be left severely alone.

Mr. Hill Griffiths asked how the last speaker proposed to distinguish between primary and secondary cases. According to Leber all such cases of tuberculosis of the iris were secondary. He would never dream of excising in any case unless the process was acute and progressive. He referred to the case of a girl who had been under observation for four years. Both eyes were affected, one of them for some time before she came to him. Recovery had taken place in the right eye, and she could read small print. Although in the other eye sight was lost, things had nevertheless quieted down.

EYESIGHT IN SCHOOLS.

Dr. Priestley Smith (Birmingham) said he had been asked to advise as to the tests on eyesight to be asked of school authorities in common with other anthropometric observations, and he read the schedule which he had decided to recommend :—

(A) *Acuteness of Vision.*—1. Hang on a wall in a good light a set of Snellen's test letters; these are in general use, and afford records which can be universally compared. No others should be substituted for them. 2. Draw a line on the floor at a distance of exactly six metres from the letters and let each pupil in turn toe this line and try to read the letters, line after line. beginning at the top, in all cases without spectacles or eye glasses. Each eye is to be tested separately, the other eye being covered, but not pressed on, by a large card held in the pupil's hand. 3. Record the vision of each eye separately in the form of a fraction, for instance, R V= 6/6 : L V= 6/18. The numerator is in all cases 6, this being the distance of the letters in metres; the denominator is the number which stands over the lowest line of letters which can be read. When the vision is less than 6/60 it should be recorded by the appropriate sign—$V < 6/60$. 4. Take care that the pupils have no opportunity of learning the letters by rote. N.B. When the vision of either eye is found to be represented by a fraction having a denominator of more than 18 it will generally be desirable to report the fact to the parent or guardian in order that proper advice may be obtained, such report being omitted if this has already been done.

(B) *Colour Vision.*—1. Use Holmgren's series of coloured wools. 2. Place them in a heap on a white cloth in a good light. 3. Lay, apart from the heap, the test-skein, a pale pure green. 4. Explain to the pupil that he is to select from the heap and place beside the test-skein all those which appear to him of the same kind of colour. Do not require him to name them or match them exactly, but to select those which are most nearly like the test-skein in colour. 5. Mix the wools again for each pupil, but always use the pale pure green as the test. A certain number of the pupils, boys, and rarely girls, will match the test-skein falsely with buffs, pinks, and other colours which have no green tint, or will hesitate much before rejecting each. These pupils are more or less colour-blind, and are thereby permanently unfitted for vocations on sea or land which require good colour-vision. Record the defect. N.B.—Ascertain by this same test that the person who conducts the colour-testing is not himself colour-blind.

The acuteness of vision of each pupil should be tested once a year, since certain defects of eyesight commonly begin during school life. The test for colour-vision need not be repeated, since colour-blindness, except that which occurs with disease of the eye, is congenital, not acquired.

The President admitted that these observations would doubtless help to throw light upon the changes which refraction underwent during school-life, but he pointed out that the value of the information would be materially enhanced if the punctum proximum were also recorded, for this would reveal any marked degree of hypermetropia.

Mr. Holmes Spicer observed that to throw the responsibility of remedying the defect upon the parents would mean in many cases that the defect would not be remedied. He had undertaken the examination of the eyes in a school in the East End of London numbering some 500 children. He found that in between 40 and 50 per cent. of the children vision did not come up to 6/12. He pointed out that an examination of this kind was a serious undertaking. It had taken him two afternoons a week for the last three months, and another two months would probably be required to complete it.

Mr. Doyne said he was greatly surprised to hear that so large a proportion as 40 per cent. of the children could not read 6/12, and asked whether this was due to coma or what? He pointed out that the punctum proximum was very difficult to obtain in children.

Mr. Spicer explained that the cause of the low vision was usually some error of refraction. In another school where a similar examination had been carried out the figures had come out about the same as his own.

Mr. Simeon Snell said there was no doubt that these examinations required much time and labour. Fortunately, the teachers themselves now showed a greater interest in the matter, and he often had children referred to him by teachers for defects of vision.

Dr. Priestley Smith, in reply, said he was quite aware that there were many difficulties surrounding the subject, and he had tried to make the process as simple and as untechnical as possible. The work ought to be done as far as possible by ophthalmologists. He said he would prefer to miss a few hypermetropics rather than entrust to a teacher a box of lens.

Mr. John Griffith read a short paper on

A RARE FORM OF INTRA-OCULAR MELANOMA.

He began by giving a brief description of the clinical aspects of the case which gave evidence of the malignancy of the growth—recurrence in less than seven months and death before the close of the year from the date of excision of the globe. He described somewhat in detail the microscopic appearance of the tumour, and pointed out the epithelial nature of the cells, a few of which not being pigmented, showed by their size, their shape, and general arrangement that they were not sarcomatous. Bleached sections confirmed this view. The small-celled stroma, owing to its marked vascularity, probably accounted for the rapid recurrence and speedy termination. Mr. Griffith paid greatest attention to the fact that the ciliary body was not, in substance, involved by the growth, conclusive evidence that the tumour had not originated in the tubular ciliary glands of Treacher Collins. He thought, however, that it had started in the tapetum ingrum of the retina, and being malignant in nature and epithelial in character, conformed rather to the type of carcinoma, yet it possessed many features dissimilar to that class of neoplasm, that it was hardly justifiable to introduce it either as an epithelioma or an alveolar carcinoma.

A jelly preparation of the tumour was shown, together with drawings of the microscopic appearance.

The President announced that in consequence of an unfortunate concatenation of circumstances there would be no Bowman Lecture in 1894.

◆

ROYAL ACADEMY OF MEDICINE IN IRELAND.

Section of State Medicine.

Meeting held Friday, April 20th.

Dr. Edgar Flinn, President, in the Chair.

SOME POINTS IN CONNECTION WITH THE ADMINISTRATION OF HOSPITAL RELIEF.

Dr. H. C. Tweedy read a paper on this subject which will be found in another column. In the discussion which followed,

Dr. Grimshaw said that although everybody admitted the facts Dr. Tweedy had stated, it was very difficult to see how they were to be remedied. As to the in-patient abuse, people should not be taken into the hospital as pay-patients unless all their circumstances having been inquired into it was found that they were in reduced straits. If patients fairly well-to-do came from the country they should take lodgings and have a medical attendant. An institution such as exists in London, Berlin, and Vienna, and which resembles a medical hotel, in which each patient could have his own medical attendant, was very much needed in Dublin. It was much more difficult to deal with the out-patient department on account of its being so hard to decide whether a person was deserving or not of advice.

Dr. Cox thought that one of the best ways to remedy this state of affairs was to give as much publicity as possible to Dr. Tweedy's paper. No doubt a great abuse existed. Frequently artisans earning £2 a week were admitted as patients into the hospital. Usually 30s. out of the £2 went in drink, and during the time of their stay in hospital the wife and children had to be supported by charity or outdoor relief, which, in the event of the patient's death, became a permanent burden on the public. He also thought there should be more co-operation between the dispensary and the hospital staffs. Very often dispensary doctors found it necessary to have patients sent to hospital on account of being unable to got proper treatment for them in their own miserable homes. Members of the hospital staff did not always keep this in mind.

Dr. Smyly said he thought that the in-patient abuse of hospitals by well-to-do people bore very heavy on specialists. Many of the so-called private hospitals at present existing were nothing better than clean lodging houses. No proper room for an operation existed in them. The time would come when the profession would have to co-operate together against this hospital abuse.

Dr. Tweedy briefly replied.

DEMONSTRATION OF THE TYPHOID BACILLUS IN DRINKING WATER.

Dr. M'Weeney read a paper on a specimen of pump-water from a village near Waterford, in which a severe outbreak of enteric fever had occurred. Dr. W. R. Morris, who had had many of the cases in his practice, suspected the water, and sent it up to Dr. M'Weeney. The pump was surrounded by manure heaps, and "slush" had been emptied into it with a view to make it work. Plate cultivations on gelatine at 22° C. were speedily destroyed by the numerous liquefying colonies present, so recourse was had to Parietti's method, by which positive results were at once obtained. The Parietti-tube, on being plated-out, proved to be pure cultivations of Eberth's bacillus, and the result was checked by microscopic examination, and culture in potatoe and in broth, to which glucose and lactose had been added, according to the plan proposed by Theobald Smith. Dr. Morris's suspicion had thus been fully justified. The journals did not seem to contain, so far as he had had time to consult them, a similar case occurring in the British Islands. Circumstantial evidence, more or less conclusive, had been adduced in many cases, but not raised to the level of certainty, by the positive result of bacteriological examination.

Dr. Thompson asked was it necessary that the putrefactive changes should be taking place in the media in which the typhoid bacilli were for the latter to have the power of causing typhoid fever in a person.

Dr. E. J. Flinn alluded to the injurious habit prevalent in many villages of throwing soiled and impure water down pumps to start their suction power. He had lately investigated an epidemic of typhoid fever in which he believed this to have been the cause.

Dr. M'Weeney, in reply to Dr. Thompson, said that this opened up a wide and difficult question. Some members of the French school held that the bacterium coli commune when growing for some time in sewers and such like media was the organism which caused typhoid fever.

The Section then adjourned.

◆

EDINBURGH MEDICO-CHIRURGICAL SOCIETY.

Meeting held Wednesday, May 2nd, 1894.

The President, Dr. T. S. Clouston, in the Chair.

Dr. Caird showed two patients who had recovered from tracheotomy for diphtheria, and two pathological specimens, one a larynx and trachea of a subject who had had a previous tracheotomy performed, and in which there was no appreciable scar; the other a cancerous growth in the larynx, in which a palliative tracheotomy gave great relief for a time.

Dr. Graham exhibited a patient who had experienced a fracture of his left superior maxilla.

Dr. Norman Walker read a paper entitled

THE COMMONER FORMS OF LUPUS VULGARIS AND THEIR TREATMENT.

Instead of dividing and subdividing cases of lupus into the numerous classes affected by many dermatologists, he thought that it was sufficient and useful to recognise only three types, all of which had one thing in common, they were tubercular. These three types he would call the catarrhal or ulcerative, the vulgaris and the fibroid. In the first form the tubercular lesions were generally masked by the growth of other organisms. The second form was really a miliary tuberculosis of the skin, especially of the superficial layers, the rete being generally unaffected. The tubercular nodules which spread the disease were most active at the margins, and varied greatly in depth. Caseation was slight. The last or fibrous form was not uncommon, but his description of it differed from that ordinarily given. The patches varied in size from that of a sixpence to six inches, and generally occurred on the limbs, almost never on the face. The affected part was of a diffuse red, the individual nodules masked by the general thickening, and there was no ulceration. The thickening and increase in the consistence of this form of lupus was not due to any true invasion of the rete, but rather to an increase of fibrous tissue between the nodules. In this last form excision of the part did fairly well, while cod-liver-oil helped, but did not cure. For treatment he laid down some general rules. The main object of course was to destroy the tubercular bacilli. Scraping was not always sufficient and should be assisted by the subsequent application of salicylic acid. In the third form scraping was of little use until the fibroid nature of the growth had been removed by repeated blistering. In destroying single nodules he had derived great benefit from the use of the cautery, either Paquelin's with a very fine point, or the galvano-cautery, for preference the latter.

Dr. Walker then showed two cases of the ulcerative form of lupus who had been treated by scraping and subsequent cauterisation with good results.

Mr. A. G. Miller divided treatment of lupus into three forms: 1. Bies's congestion treatment; 2. Scraping; 3. Excision. Bies's congestion method had a great power in checking the spread of the disease, and combined with thorough scraping was a good one. Scraping to be of any use had to be thorough. Of the three areas in any cases of lupus, namely, the cicatrised, the cicatrising, and the spreading, only the last required scraping although the second was not the worse for it. In treating lupus in this way Volkman's sharp spoon was of little use as it was too large. A small sharp spoon of a size to readily scrape out each individual nodule was much better. Another adjunct to the treatment was to touch the parts after scraping with pure carbolic acid and then again to remove with the spoon the white pellicle formed. Excision again must be very free as outside the macroscopic nodules there were often others of microscopic size which required removal also.

Mr. Miller then showed a patient who had been scraped and otherwise treated under chloroform for lupus no less than forty-eight times with a very fair result.

Dr. Allan Jamieson thought that Dr. Walker's third class was hardly required as it was simply Class 2 with a slight increase of fibrous tissue. He had found pure carbolic acid of some good, while he thought that the induction of an attack of erysipelas resulted in little permanent benefit, although the immediate effect was palliative. He had found exposure to cold in all lupus cases very meretricious.

Mr. Joseph Bell advised free excision if the lupus was not on the face, or otherwise thorough scraping combined with the use of chromic acid.

Mr. Alexis Thomson had found skin grafting by Thiersch's method of great value after excision.

Dr. Alexander Bruce read a paper on

TWO CASES OF NODOSE PERIARTERITIS OF SYPHILITIC ORIGIN.

There were two forms of periarteritis, the first affecting the small vessels of the body generally and not specific in origin, the other confined to the smaller vessels of the brain and always syphilitic. The two cases, notes of which he placed before the society, belonged to the latter category. In both these cases the patients were nurses, one male the other female, who had contracted syphilis in the pursuit of their duties. In both the secondary symptoms were severe and the tertiary symptoms appeared early, in one within two years, in the other after only nine months. A fatal termination with paralytic symptoms soon followed. The arteries of the brain showed a great thickening of their outer coat, with an almost normal condition of the intima and muscular layer. The thickening consisted largely of round cell infiltration breaking down in parts into caseating areas. He thought that periarteritis was a commoner disease than was generally supposed.

◆

Dr. Leon Labbe, formerly of the Hôtel Dieu Hospital, died in Paris last week. He was the son of a general practitioner in a country commune, that of St. Christophe (Indre-et-Loire), where he was born in 1827. He took his degree in Paris, and, at the age of 45, was appointed Surgeon to the Hospital for Incurables, in 1874 to the Dubois private hospital, where he practised until 1889, and in that year to the Hôtel Dieu, which hospital he left on attaining his 62nd year.

France.

[From our own Correspondent.]

Paris, May 12th.

Anæsthetics.

At the last meeting of the Societé de Chirurgie M. Segond spoke on the different methods of applying anæsthetics and their composition. He said that for the last year all his operations were done under bromide of ethyle alone or inhalations of ethyle followed by that of chloroform. When the operation was of short duration the former anæsthetic sufficed alone, but it was not so when the operation was lengthy, grave, and tedious, such as hysterectomies, laparotomies, &c. No accident had ever been witnessed out of the 443 cases. He always administered the anæsthetic to the patient in the dorsal decubitus, and where the bromide of ethyle alone was used he poured at first a few drops on a compress and presented it to the patient in order to accustom him as it were to the odour of the liquid, after which a large dose was thrown on the fold, which was pressed firmly over the mouth so as to prevent all communication with the free air. In twenty seconds resolution was complete and the period of excitement was frequently wanting. Where the effect of an anæsthetic had to be kept up for some considerable time a few drops of chloroform were applied from time to time.

M. Bazy said that he had tried bromide of ethyle in a certain number of cases and found it satisfactory.

M. Monod gave similar testimony to the merits of bromide of ethyle, but said that at the first moments of the inhalation the patient was seized with such a terrible sensation of anguish and suffocation that the speaker preferred without hesitation using chloroform.

M. Berger and several other members expressed themselves in the same sense.

Acute Tonsillitis.

Guaiacol is certainly having, as our American cousins say, a "boom" with practitioners. It was introduced to the profession a few years ago as a specific for pulmonary diseases (chronic), acting more rapidly than the old time-honoured creosote. Later on it was considered a powerful antithermic when rubbed into the folds of the skin, and several articles were written on its advantages. Later still guaiacol was recommended as the best application for relieving the pain of orchitis, as already reported in this journal, and to-day a practitioner of no mean repute exults over the success he has had with the drug in the treatment of acute tonsillitis or common sore throat. It seems that guaiacol, when painted over the inflamed tonsil, promptly eases the pain and the fever falls, while the tumefaction of the glands rapidly diminishes. Every one knows what an extremely painful affection tonsillitis is, and if guaiacol really produces the effects claimed for it many a patient will be grateful to his medical attendant.

Germany.

[From our own Correspondent.]

Berlin, May 11th.

THE SURGICAL CONGRESS.

I this week continue my *résumé* of the principal papers and discussions at this important gathering.

In the afternoon sitting of the first day Dr. Habs, Madgeburg, showed eighteen cases of

Exarticulation of the Knee-joint

performed by the late Dr. Hagedorn. The deceased surgical director of the Madgeburg Hospital, had once expressed the wish that the cases operated on by him should in ten years time be shown to the Congress, in order that they might judge of the final results, and his assistant had taken the opportunity of carrying out the wish of his late master. Hagedorn's method consisted essentially in the retention of the patella, and using it as a support to the stump by flaps from behind. An anterior flap served to cover the supporting surface. The patients shown had mostly been operated on for over ten years, one even fourteen years, and only a few from more recent times were grouped with them. In all the usefulness of the leg was excellent; all were able to run securely on their artificial legs, and with comfort and endurance. A girl operated on fourteen years was able on her own showing to dance a whole night through without missing a single dance. A labourer was able to carry hundred-weight sacks up steps, and made use of a stick only to make his direction more sure. The stump after so many years showed a diminished volume, but this was due to arrested growth, and not to any actual shrinkage.

Prof. Küster, Marburg, then spoke on

RHINOPLASTY FROM THE ARM.

The present method of obtaining the flap from the forehead left such a disfiguring and conspicuous scar that he had returned to the old Italian method of Branca. This method had been abandoned on account of the difficulty of carrying it out, and of the accidental traumatic diseases that sometimes followed. Both these objections were now overcome. In a girl of 19, shown, in whom the tip of the nose was destroyed by lupus, the flap had been taken from the arm and the arm fixed to the head by a plaster of Paris bandage. Healing took place in seven days. At first the discomfort was easily borne, but later on morphia had to be given to alleviate it. The healing was perfect, and the artificial tip could only be recognised from a few delicate cicatricial lines that were visible.

THE RESULTS OF CONSERVATIVE TREATMENT OF HIP-JOINT DISEASE.

Prof. Bruns, of Tübingen, said:—

Various changes have taken place in the treatment of the disease during the past twenty years, and even now surgeons are not by any means of one mind as to the best course to pursue. The minority still hold to operative treatment, whilst the majority have given this up, and have advanced to a more conservative, and expectant line of action. Prof. Bruns has made exhaustive inquiries into the results of both methods, and has come to the conclusion that the latter shows at least as good results as the former. In the Tübingen clinic, during the last forty years records have been kept of all cases treated. Six hundred cases were treated during this period, and later examinations were made in the case of two hundred of them. From the data at his command, it was shown that tubercular hip-joint disease, almost without exception, occurred before the twentieth year of life, that 50 per cent. recovered after a four years' illness. Forty per cent. of all cases ended fatally from tubercular disease of other organs or general tuberculosis. Of the non-suppurating cases, 77 per cent. recovered; of the suppurative 22 per cent. The prospect of recovery became worse the higher the age. Even recovered cases often died of subsequent tuberculosis. Those permanently recovered mostly gave the impression of perfect health, and showed a note-worthy usefulness of the limb affected, which was only limited by the angular position of it. As a rule, a partial or total ankylosis of the hip-joint remained. As regarded usefulness, the shortening of the limb was of less importance than the flexion of the legs.

The speaker then drew a comparison between the results obtained by the different methods of treatment, and came to the conclusion that the prospects in resection of tubercular joints were gloomy. Resection gave no better results functionally than the conservative method of treatment, and should only be adopted where the conservative method was impracticable, or where it had been tried and led to no result. In the meantime, however, he would withhold his definitive judgment, as a sufficient amount of experience with the modern treatment of wounds was wanting.

Hr. Schede (Hamburg) agreed with the opinions of the previous speaker and discussed in detail the advantages of injection of iodoform glycerine into the tuberculous joint, which in a moiety of the cases rendered resection unnecessary.

Prof. Helferich, Greifswald, emphasised the necessity of long-continued treatment. No cure was brought about by resection and cicatrisation of the wound. If treatment was not continued serious disturbances were certain to arise later. For this reason resection could not be looked upon as a finality; care had also to be taken to ensure a good position of the leg. Generally, those who were discharged as cured after resection came back again later in a bad condition in consequence of an unsuitable mode of life after withdrawal from medical supervision. Ankylosis from this cause frequently came on years afterwards. For these reasons the greatest attention had to be paid for years to the hygienic surroundings of the patient, as well as to the condition of the recovered bone, if the result obtained at first was not to be jeopardised. The speaker pointed out England, where special hospitals for children with coxitis were erected, with affiliation on the sea-coast or in the country. The patients remained there for years under medical observation, the position of the limb was perseveringly controlled and improved, and the nutrition of the children improved as much as possible. Such institutions could easily be carried on on the German coasts.

Prof. Gussenbauer, Prague, represented the extreme standpoint of conservative treatment of cases of tubercular coxitis, and would rather not have them touched, whilst Prof. v. Bergmann was more in favour of operative treatment, which in cases of profuse suppuration was the only course open. Prof. Bramann, Halle, preferred resection to be limited to those cases in which the acetabulum was known to be diseased, and referred to eleven such cases in which he had performed resection. In conclusion, Prof. Madelung, Rostock, noted that the prospects of conservative treatment became better when the patients we'e taught to go about for long periods in a suitable apparatus.

◆

Austria.

[FROM OUR OWN CORRESPONDENT.]

VIENNA, May 11th.

FOLLICULITIS INDURATIVA.

DR. EHRMANN showed a man to the Gesellschaft from San Francisco who nine years ago acquired anthrax in the neck, which became indurated. When Ehrmann saw the man first there were several openings discharging pus, and when the skin was closely examined the hairs could be observed to be in little bundles; microscopic examination revealed staphylococcus pyogenes aureus. The sound when entered into one of the openings passed into a cavity whose periphery seeemed to pass externally. After painting the whole with iodine it seemed to improve, but again another crop of swellings appeared in the hair follicles.

In the lower half of the neck all the follicles were quite open; electrolysis was applied and the whole neck rapidly healed up.

This appeared to him to be a case of staphylococcus invasion of the hair follicles arising from a congenital abnormal condition of the sac; the sycosis which followed was probably due to this peculiarity which soon produced a chronic hardening of the follicle.

"Methodische Hörubungen."

Prof. Urbantschitsch again brought his reputed new method of treatment before the Gesellschaft in the form of a lecture. This consists of selecting different sounds which are regularly produced at the ear of the deaf until he becomes familiar with them. The sounds should be continued five to ten minutes daily, or at least three times a week. This treatment is reputed to act like magic on the young, but is slower in operation in the aged. Much depends upon the voice, however, in awakening the perceptive power, as the high and deep tones are not equal in effect. The intervals must be filled in gradually with inter-tones. If a correct record be kept during the treatment, the right ear will probably differ from the left during the period. After the perception of speech, musical tones should be practised. Urbantschitsch has constructed a harmonica with five and a half octaves, which answers this training admirably. As to the time this treatment must be continued, no limit is fixed, different cases requiring different durations before reaction sets in. Total deafness being rare, it is considered that this treatment must affect a large number of the two hundred thousand alleged, by statistics, to be helplessly deaf in Europe. Another difficulty he pointed out in educating these unhappy patients was the mental condition. In many of these cases, the mind isweak, intelligence low, and education difficult to impart even in healthy ears, hence we find children making rapid progress under treatment.

The practical worth of this treatment is often questioned f it be worth the trouble, but from a mere social point there is only one answer. Since commencing his treatment in "The Landesanstalt" sixty cases have been regularly under treatment. At the beginning of the course not one could hear a sentence; six of them could hear a word; twenty-two could perceive vocal sounds, while thirty-two had a trace of hearing. To-day twelve could follow sentences, sixteen words, twenty-one vocal sounds, and eleven a trace of hearing.

Professor Gruber agreed with Urbantschitsch in the training of the young, but considered the time far too limited to pass a definite opinion. He recollected visiting the Israelitish deaf institution thirty years ago, where the director practised this treatment with vocal sounds and could recall many cases of children rapidly improving.

Toynbee and Hinton, in their handbook of Aural Disease, record many favourable results by these otitic gymnastics. He also related the cases of several families who have quite recovered by this slow treatment.

Prof. Politzer agreed with much that had been said by Urbantschitsch, but was not so sanguine of the future results. The treatment was not new, and therefore had a longer trial both in Germany and France. Verrier, with several of his colleagues, had practised it for some years, but finally abandoned it. From the pathological alterations that gradually take place in the deaf, such as thickening in the labyrinth, fibrous tissue, bony neoplasms, ankylosis of the stapes, and atrophy of the nerves.

In congenital cases a portion of the functional power of hearing is left which may be extended, and many of these cases greatly improve without any treatment whatever.

◆

The Operating Theatres.

THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

Cleft Palate.—Mr. Owen operated upon an infant of 18 months for cleft palate. The patient was placed on its back with the head hung over the end of the table. The tongue was drawn well forward by a looped suture passed through the tip. A Smith's gag was used and answered well. Mr. Owen called attention to the fact that he detached the muco-periosteum from the back of the hard palate in order to gain a slackness of tissue at the anterior part of the cleft in the velum. He still further diminished tension by lateral incisions passing through the soft palate parallel to the line of the sutures. Some of the sutures were of silver wire, and some of horse-hair.

Talipes Calcaneus.—The same surgeon's next case was a child with infantile paralysis and talipes calcaneus. Having exposed the tendo Achillis he divided it by two parallel oblique incisions, about ½in. apart. The intermediate piece of the tendon being removed, he approximated the cut surfaces, and adjusted them by three horse-hair sutures. The foot was then put up in the extended position in lateral splints of house-flannel and plaster of Paris.

Traumatic Urethral Fistula.—Mr. Owen next operated on a boy of ten years, who, he said, had been admitted about a month previously with an œdematous penis, and a history of incontinence of urine. On placing him under chloroform the house surgeon had then found that all the urine was discharged through an opening at the scrotal end of the penis. The opening had been caused by the pressure of a small brass ring which, under chloroform, was discovered imbedded in a deep groove of granulation tissue. The ring was removed, and also the chief part of the very œdematous prepuce. Since that time almost all the urine had escaped by the fistula, and the cicatricial contraction against the wound had rendered it a difficult matter to pass any instrument into the bladder. When an instrument had been passed, however, it was seen that a considerable extent of the floor of the urethra had sloughed away. Obviously any attempt then to perform a plastic operation on the urethra would have been futile. The operator remarked that the only thing to be done was to establish a perineal drain, and that when the urine was thus diverted from the urethra it would be seen whether an operation would or would not be needed to close the fistula. He therefore performed median perineal cystotomy on a straight staff, leaving a soft tube in the bladder wound.

THE CANCER HOSPITAL.

Epithelioma of the Tongue, with Enlargement of the Submaxillary Lymphatic Glands.—Mr. Cotterell operated upon this case, which occurred in a man, æt. 51. There was epithelioma of the right under side of the tongue, which involved the floor of the mouth to a slight extent. There was also secondary infiltration of the submaxillary lymphatic glands, most marked on the right side. An incision was made in the right submaxillary region similar to that used when the lingual is tied under the hyoglossus, but extending a little further backwards. The submaxillary space was then cleared out, all glands being removed. The lingual artery was ligatured as it passed under the hyoglossus muscle. The opposite side was treated in a similar manner. A gag was then put in the mouth, and the whole of the tongue removed with scissors. There was no bleeding from the tongue. Mr. Cotterell remarked that he advocated removal of the submaxillary glands in all cases of removal of the tongue, the lymphatic glands in this region being frequently small, but being more often infected than is imagined, and the rapid recurrence of the disease in many cases, he thought, is due to their not being removed. It is convenient at the same time, he said, to remove the submaxillary salivary glands, as the lymphatic glands are sometimes adherent to them, and hidden by them; moreover, their removal prevents, to a large degree, the slobbering which patients complain of after removal of the tongue. The removal of the submaxillary glands necessitates the ligature of the facial in two places, before and after leaving the gland. The advantage of preliminary ligature of the lingual arteries, he thought, was too well known to comment on. He pointed out that in those cases where the floor of the mouth was extensively diseased Kocher's operation offers the best chance for the patient, but in ordinary cases removal of all submaxillary glands, preliminary ligature of the linguals, and then removal of the tongue, is probably the best operation yet devised. It can be very rapidly performed, there is no intra-oral bleeding, and he had not met with a case of septic pneumonia afterwards. This latter disease is, he was convinced, very frequently caused by blood trickling into the trachea and bronchi *during anæsthesia*, but he considered that if the linguals are first tied this accident is entirely prevented.

GREAT NORTHERN HOSPITAL.

Varicocele—New Way of Tying the Veins.—In operating on a patient for varicocele, Mr. **Macready** employed a method for ligaturing the veins which has been suggested by Dr. Malcolm, the anæsthetist of the hospital. The operation was performed by an incision just above the external ring, going up towards the internal ring. Mr. Macready (who possesses the great advantage to the surgeon of being ambidextrous) next isolated the vas, which was held out of the way, and then freed the enlarged vein; this was then held up in the form of an inverted V, a loop of silk was passed under the V, then (after being opened) over the instrument holding up the V and down each side of it, one free end of the silk being next passed through the loop, and both free ends securely tied, thus forming the Staffordshire knot; the portion of veins above [the ligature forming the apex of the V was then cut off, and the whole wound closed. By this method, the cut ends of the veins are securely attached without further ligature. The advantages claimed by this process are, that one ligature and one knot are used instead of the two ligatures and the three knots of the ordinary method of ligaturing the veins in two places, cutting away the intermediate portion, and tying the two ligatures; also that the testicle is well and thoroughly drawn up.

Resection of Inguinal Artificial Anus—(Sequel to the Case reported in last week's "Operating Theatres.").—Mr. **Herbert Allingham** remarked that the patient had recovered from the previous operation, but all the motions were passing by the inguinal opening, and the spur about the opening was getting more prominent, in spite of an attempt to reduce it by daily pressure with the finger. This being the case, it appeared to him useless to attempt any plastic operation to close the artificial anus. The patient having been anæsthetised, a sponge was first put into the artificial anus. The skin around the artificial anus was then divided, and the peritoneum opened as soon as the mass was entirely freed from the skin around; the anus and gut were next pulled well out of the abdomen. To do this it was necessary to separate some omentum from the gut, it having become adherent to it as a result of the fixing up the gut to the opening in the belly wall at the first operation. The sigmoid flexure having a fairly long mesentery, it was easily drawn well out of the belly. The abdominal cavity being well protected by sponges, two drainage tubes were passed through the mesentery and secured with clip forceps around the gut about three inches above and below the artificial anus. About four inches of the gut with the anal opening in it were then cut away, a piece of the mesentery being also divided. A continuous silk suture was used to bring the mucous membrane of the upper end of the gut to the mucous membrane of the lower end of the divided gut. This suture was passed from one to the other very loosely all around. Then a Mayo Robson's bobbin was inserted between the loose stitches into both ends of the divided gut, and when well inserted the continuous stitch was drawn up tight, so bringing the mucous membrane of both ends of the gut firmly together over the bobbin, the bobbin acting as an excellent frame to keep the ends of the bowel together and also to allow of the careful insertion of Lembert's sutures uniting the peritoneal surface of the upper to the lower end of the divided gut. A few sutures were then used to unite the cut in the mesentery. The bowel was then washed and returned, the abdominal wound being united with silkworm gut suture in the usual manner.

It is satisfactory to note that the patient has made a perfect recovery and has left the hospital.

The Medical Press & Circular.

"SALUS POPULI SUPREMA LEX."

WEDNESDAY, MAY 16, 1894.

THE DENTAL FUNCTIONS OF THE GENERAL MEDICAL COUNCIL.

In the issue of The Medical Press and Circular of April 18th, we felt "it necessary to say that the General Medical Council has made and is making itself the servant of the British Dental Association by making and altering regulations to suit the views of that organisation," and we published extracts from the Minutes of the Council itself which, we think, showed beyond the possibility of controversy, that, to avoid the "injustice done to the licentiates of the British bodies (*mutato nomine*, the British Dental Association) by placing them on the same level as the Diplomates of the American Colleges," the General Medical Council had decided to abrogate the function of registering foreign Diplomates which Parliament had confided to it, and had, in fact, refused recognition to institutions and to Diplomates thereof whose qualifications the Council itself had declared "furnish guarantees of the requisite knowledge and skill." With reference to this transaction we have only to repeat that, in our judgment, the Council has been very badly advised, has weakly adopted the policy of an interested trade organisation, has acted with perfect illegality, and might be made amenable to the influence of Parliament by any Member of the House who thought it worth his while to bring the proceedings before public notice. We revert to-day to the consideration of the Dental policy of the Council because we are aware that a proposition will be made to the approaching meeting, the effect, if not the intention, of which, will be the aggrandisement of the class of dental practitioners whom the British Dental Association represent at the expense of those with whom it is not in sympathy. The case stands thus:—After the passing of the Dentists' Act in 1879, certain recommendations, suggested, we believe by the British Dental Association, were made by the General Medical Council to the Licensing Bodies as to the courses of study which they should require from future candidates for a Diploma in Dentistry. One of these requirements was that the candidate should produce a certificate of three years' service as apprentice to a Registered Dentist, in addition to proof of 45 months' study of Mechanical Dentistry in an institution recognised for that purpose. The Irish College of Surgeons, for a couple of years, conformed strictly to this recommendation and refused to admit any candidate without the three years' apprenticeship certificate, with the result that its Dental Diploma was completely extinguished as a qualification for anyone save a registered dentist, who was not subject under the rules to the apprenticeship service. In the whole period during which the apprenticeship was insisted on we believe that one candidate only presented himself to the Irish College for examination. For that reason the College reconsidered the matter and agreed to alter its regulations so as to make the 45 months' study of Mechanical Dentistry an essential, and to make the apprenticeship merely a recommendation. This change did not suit the British Dental Association, and they, put in motion by the Dublin Branch, have put pressure upon the General Medical Council to induce it to compel the Irish College to make the three years' apprenticeship indispensable. Let us first discuss the propriety of an enforced apprenticeship certificate, without regard to the special case of Ireland. We submit that the retention of the apprenticeship system is an anachronism—that it ceased long years ago to be regarded as essential for qualifications in Medicine, Surgery, Midwifery, or anything else, because it became notorious that an apprenticeship certificate meant, usually, nothing but a receipt for a fee paid, and that the supervising authority (in this case the General Medical Council) could have no possible means of proving the *bona fides* of the teaching certified. Therefore, we urge that, in the case of dentists, apprenticeship should not be insisted on any more than it is insisted on as a qualification for other diplomas. Second, we submit that the imposition of a three years' course of anything is a bitter hardship upon dental practitioners who desire to obtain a registrable qualification. There are hundreds of dental assistants throughout the kingdom who have worked at their business with brain and finger for three times three years, and yet could not produce a formal indenture of apprenticeship, and it is a monstrous injustice, in our opinion, to condemn them to lifelong ostracism from their profession because it is impossible for them, many of them being middle-aged married men with families, to enter again as pupils and pay an apprenticeship fee. Third, we object because it is obvious that the apprenticeship must be either a reality or a sham. If a reality it means the payment of £150 to £200 by the student and the outlay of three years of life for a questionable educational benefit; if desired to be a sham, the facilities afforded are attractive, inasmuch as any of the 4,795 dentists whose names appear on the Register can give, with or without money consideration, and with or without professional service, a scrap of paper which will serve the purpose of the General Medical Council as well as a more imposing document. We are conscious that the General Medical Council professes unconsciousness, in all matters of medical education, of this latter consideration. It keeps on improving medical education by imposing new courses which look well on paper, but are seldom fulfilled, and the apprenticeship in Dentistry may be one of these. As regards the Diploma in Dentistry of the Irish College of Surgeons, against which the attack of the British Dental Association is directed, it is as well that it should be understood that the circumstances are special. Ireland does not afford the facilities to which we have referred of satisfying the requirements of the General Medical Council by a sham apprenticeship certificate. In Ireland the teaching of dentists is practically in the hands of a dozen practitioners, to one or other of whom the apprenticeship fee of £200 or £150 has to be paid, there being practically no other way for the student's escape from the difficulty. The imposition of that fee and of the three years of service has, in effect, choked off Ireland as a centre of dental teaching, and if the General Medical Council insists on retaining that mulct, dental licensing in Ireland must cease. We may add the expression of our conviction that if the Irish College of Surgeons thinks it desirable to resist coercion in this matter, and lays the facts which we have stated, and others to the same effect, before the Privy Council, that body will refuse its sanction to the perpetuation of the effete apprenticeship system, even for the monetary benefit of a limited number of dental surgeons.

◆

DR. ANDERSON AND THE COLONIAL JUDGES.

The trial of the action brought by Dr. Anderson against Sir John Gorrie, Mr. Justice Lumb, and Mr. Justice Cook for maladministration of justice in the islands of Trinidad and Tobago, has been brought to an end. This prolonged litigation has ended in the complete justification of the plaintiff, and has exposed a tale of arrogance, incapacity, and blundering injustice unparalleled even in the annals of colonial government. Of the three judges mentioned, who formed the Supreme Court of the Colony, one only has been convicted. Sir John Gorrie, the Chief Justice, died soon after the action was brought, and Mr. Justice Lumb was honourably acquitted, the only remaining defendant being Mr. Justice Cook, who will have to bear the brunt of the decision. The chief charge against him was that he ordered Dr. Anderson to find bail for £1,000 on a petty judgment of £42, and committed him to prison when he refused to fulfil what he regarded as a monstrous demand. The charges against Sir John Gorrie are admirably summed up by a contemporary in the following passage: "Sir John Gorrie has been acquitted of any corrupt or unworthy motives; his case appears to be that of a somewhat irascible and obstinate man who desired to appear a strong judge without the necessary qualifications fitting that difficult part. He came to the colony with some sort of idea that it was his duty to back up the 'natives' against the Europeans. In a country where a compact aristocracy of landowning planters practically control the lives and destinies of ten times their number of native peasantry, this idea was not without its justification. His mistake was attempting to do too much, and, greater still, in doing it in a most intemperate and high-handed fashion. Where the means at his command were not sanctioned by law he did not hesitate at illegalities. He encouraged the native peasantry to bring actions *in forma pauperis* against their landlords, one of whom was Dr. Anderson; he refused to hear defendants upon their oath, interfered with the rights of mortgagees, and was apparently ready to use his arbitrary power of committing for contempt of court wherever criticism obtruded itself." It was against such a man that Dr. Anderson found himself in collision. The latter has embarked in a long fight against injustice and persecution that might well have broken the energies of any man of average determination. In the end he has triumphed, it is true, but at what a cost to himself! At the outset of these disputes between the planters and the judicial bench Dr. Anderson occupied a good social position as a magistrate, a medical man, and a planter, and was possessed of considerable means. Now he is penniless and ruined, and the startling part of this object lesson in unwise litigation is that the illegality of his persecution has been proved up to the hilt. Worst of all, it is possible that on technical grounds the verdict of £500 which was returned in his favour may not be recoverable. The case of Dr. Anderson, then, is a very hard one, and it "points a moral and adorns a tale" which will be of some service to those who, under similar circumstances, are anxious to seek the aid of the law.

◆

HONORIS CAUSA.

The claims of medical men to titles and rewards, it has been pointed out again and again, are not recognised by the State at anything like their relative value in comparison with other classes of the community. It affords us much satisfaction, therefore, to see that the subject has been taken up in earnest by our contemporaries. Great as the services of the profession have been in the past, it is probable that with the onward march of science a still richer harvest of achievement will be found to lie beyond the horizon of present knowledge. Indeed, some enthusiasts do not hesitate to assert their belief that we must look to preventive medicine as the chief lever for the future happiness of the human race. Nothing seems impossible to a body of men who have practically robbed such scourges as small-pox and cholera of their terrors, at any rate so far as our country is concerned. And yet, while places, peerages, and pensions are showered on other public servants, such as politicians, army or navy men, landed or other plutocrats, wealthy brewers or commercial kings, no such substantial rewards are conferred *honoris causa* on medical men. The only way in which a member of the profession may hope to obtain high titular distinction would be by severing his connection with medicine and embracing politics instead. Our present purpose is to call attention to a medical man who is deserving of distinguished recognition for extra-professional public services. We refer to Dr. J. C. Bucknill, the originator of our Volunteer system. Into the merits of that force, as a branch of the national defence, it is not necessary to enter. It may be taken as granted that to the introduction of the voluntary system the movement has owed its continuous and phenomenal success. The existence of the Volunteers enables us to keep down the numbers of our regular forces, and so to save the country the very large expenditure that would be necessary to keep England on a war footing with the other European Powers. At the same time it enables us to avoid conscription, the compulsory term of military service which taxes so severely the resources and the patience of Continental citizens. Our Volunteers thus save the national exchequer from an enormous expenditure, while they constitute a reserve fighting force of great potential value, and are a standing embodiment of the freedom of action so dear to Englishmen. Such are a few of the chief principles and developments of the movement, the existence of which we owe to the creative genius of a medical man. Forty-two years ago, Dr. Bucknill suggested the idea of a Volunteer force, and a little later he actually organised the first corps which was raised in England. At the time mentioned he was acting as Principal Medical Officer to the Devon County Asylum at Exminster. By his energy the Exeter and South Devon Rifle Corps, the first body of Volunteers whose services were accepted by the Queen, was formally enrolled. The originator of this great movement is now living in retirement at Bournemouth. He is advanced in years and infirm, but these facts need offer no obstacle to the conferring of any honour that Her Majesty, or Her Majesty's advisers may see fit to confer. Certainly a review of the honours lists of the last 40 years will reveal many that have been granted for less substantial services than those of Dr. Bucknill. By bestowing on the founder of the Volunteer system a K.C.B. or other fitting honour, Her Majesty will be paying a compliment not only to an important branch of the Army service, but also, indirectly, to the members of a loyal profession.

Notes on Current Topics.

A Coroner on the Maternity Department of Hospitals.

CORONERS, of course, are entitled to their opinion in common with other persons, and, just like other persons, they are disposed to attacks of petulance which are calculated to make them say silly things. An instance in which a coroner delivered himself of some absurd remarks has just come under our notice. An inquest was held last week at St. Luke's Coroner's Court concerning the death of a newly-born child, the son of a French polisher. The mother was attended during her confinement by a student of St. Bartholomew's Hospital, and in the course of a few hours afterwards the child died. It was shown that death was due to inanition, the result of premature birth. The facts of the case having thus been stated, the coroner said that the country was put to the expense of holding an inquest in consequence of the authorities at St. Bartholomew's Hospital sending students to attend cases of confinement, inferring by this that had a qualified man attended a certificate of death could have been given in the ordinary way. Obviously, the coroner must have been labouring under a feeling of irritation in consequence of having to hold an inquest for so trivial a cause—and probably he felt it impossible to avoid saying something which would have the effect of throwing the blame upon some one. Unfortunately, however, for himself he could not have made a more fatuous accusation. He must have known perfectly well what the working of the Maternity departments at the large hospitals is, and that the poor classes are glad to be attended by the students, under the supervision of the Midwifery Assistants. To have pretended, therefore, that the confinement cases at hospitals should be attended by qualified men, and not by students, and, inferentially, to have cast blame upon the hospital authorities for permitting the students to attend, was entirely unworthy of the position which he occupied. Clearly, it is the duty of coroners to endeavour to smooth away any sources of friction which may arise between the great hospitals with medical schools and the public, instead of acting in such a manner as to create ill-feeling, discontentment, or want of confidence towards the institutions. The poor classes are only too apt to assimilate reports or suggestions which seem to tell against the hospitals, whose aid they seek in times of sickness and need, although these reports may be absolutely without foundation. Quite possibly, owing to the publicity given to the coroner's remarks above quoted, a great deal of harm has been done to the working of the Maternity department at St. Bartholomew's. At all events, the remarks in question could only have had this tendency. But it is plain that the coroner never considered for a moment that in casting indirectly a slur upon the working of this department of a great public charity, he was doing that which would tend to disturb the confidence held in it by those who seek its aid, and that in consequence discredit would be certain to be thrown upon the same departments among the hospitals throughout the metropolis. We repeat that his remarks contained a perfectly gratuitous accusation. If for his own sake he was wishful to avoid having to hold inquests of the kind in the future, it would have been easy for him to have suggested the expediency of the students calling in the assistance of the Midwifery Assistant whenever it appeared that the new-born child could not survive more than a few hours.

Hospital Abuse.

SOME interesting points have been advanced in the course of the newspaper warfare that has lately been raging over the question of hospital abuse. Among them is the monstrous assertion that medical men have no right to protect themselves against unfair competition. In dealing with the proposal that no one should be allowed to consult a member of a hospital staff at a hospital without first obtaining the permission of a general practitioner, one writer remarks: "Now, Sir, I deny the right of general practitioners to institute a medical inquisition for the advancement of their own interests." The individual who thus boldly lays down ethical laws for the medical profession can hardly have considered the full bearings of the case. If his proposition be, as we take it, that medical men have no right to unite for purposes of common protection, then there can be no earthly reason, so far as one can see, why a similar rule should not apply to lawyers, to cornchandlers, to plumbers, to licensed victuallers, or to the thousand and one trades and handicrafts that have provided themselves with actual or virtual trades unions. The same correspondent appeals to the subscribers of hospitals to protest against the proposition of a gentleman writing to the *Echo* under the title "M.D." "The public," he says, "should not be allowed to judge of the suitability of their cases, but should in all cases, whether of accident or disease, appeal to medical men in practice." An attempt is made to reduce the argument in favour of such an appeal to an absurdity by suggesting that in case of accident it would be extremely cruel to allow an injured person to wait in agony for a doctor's permission to be treated at hospital. So far as we know, no one has advanced any objection against the immediate treatment of accidents and emergencies at hospitals. Supposing, however, a patient in good circumstances goes to a hospital for a surgical injury, such as a sprain, an uncomplicated wound, or a fracture, is there any reason why he should not be treated once and then handed over to a local practitioner? The continued treatment of a well-to-do patient under such circumstances constitutes an obviously unfair competition on the part of the hospitals against the outside profession.

Folkestone and its Casuals.

Some months since, the public was startled by the account of how Folkestone sends its tramps to an unwholesome casual ward at Elham, several miles away from the town. In this "ward," which is in reality part of a stable, men, women, and children were huddled indiscriminately on bare boards, or on a brick floor. Ventilation was practically absent, and there were several open drains. After the exposure of this shocking state of affairs in the public press, and the general indignation that was aroused, it is hardly creditable that nothing has been done to amend or alter this standing disgrace to Poor-law administration. Yet such appears to be the case, for lately, at a meeting of the Folkestone Municipal Reform League, a working man related how he had pass a night as an amateur casual in the stable at Elham. Amongst other things, he stated he shared a rug with two others, who slept, or rather endeavoured to sleep, on the bare boards. In his case, sleep was prevented by the rats, which kept running over him. At a subsequent meeting of guardians, called together to discuss the subject, a Mr. Horton remarked that there was "at any rate, no need to put horses in the stable, and certainly he would not like to put his own horse there." The Local Government Board is notoriously slow in taking action, but surely delay in a case like this is little short of criminal. Why should Folkestone be allowed to establish a "black hole" of this kind for its casuals miles outside the town?

The New Fellows of the Royal Society.

The following fifteen candidates were selected on the 10th inst. by the Council of the Royal Society, to be recommended for election into the Society—Mr. W. Bateson, Mr. G. A. Boulenger, Dr. J. R. Bradford, Mr. H. L. Callendar, Professor W. W. Cheyne, Mr. R. E. Froude, Professor M. J. M. Hill, Professor J. V. Jones, Mr. A. E. H. Love, Mr. R. Lydekker, Mr. F. C. Penrose, Dr. D. H. Scott, Revd. F. J. Smith, Mr. J. W. Swan, and Mr. V. H. Veley. We are glad to see in the above list the name of Mr. Watson Cheyne. This recognition of his work in the field of scientific surgery is well merited. Next, perhaps, to Sir Joseph Lister, whose pupil he was, he has done more than any other surgeon to advance the teaching of the principles of antisepticism. His original work has been mainly in the direction of bacteriology in relation to surgical diseases, of which his Astley Cooper Prize Essay, "On the Origin, Anatomy, Results, and Treatment of Tuberculous Diseases of Bones and Joints," is an example. Dr. Bradford's claim to the "Blue Ribbon" of science is based upon original investigations in physiology, such as papers on "The Innervation of the Renal Blood Vessels," "Innervation of the Pulmonary Blood Vessels," and "Some Points in the Physiology of Gland Nerves."

New Method of Tying the Veins in Varicocele.

Any new method introduced into the smallest operation is always interesting to the surgeon, and certainly the procedure reported in "Operating Theatres" of this week, has the merit of simplicity, and seems to fully carry out all the advantages which are claimed for it. The employment of the Staffordshire knot for tying the venous cord in the operation of varicocele must undoubtedly shorten the operation, as one ligature is used instead of two, and one knot tied instead of three; besides, the whole venous portion of the cord is pulled up and kept securely *in situ*. Another advantage might be claimed for this method, namely, that the surgeon, having completely to free the enlarged vein, or plexus of veins, and pull it up in the form of a V, is absolutely certain not to include the vas in any of his ligatures. The operation by this method must evidently always be performed in the groin and not in the scrotum. In the former position, as many surgeons have pointed out, one venous cord is generally met with, and not several, as in the latter situation; this last condition would necessarily militate against the employment of the Staffordshire knot.

Sectarianism in Medicine.

From time to time disagreeable incidents crop up here and there which show that the old spirit of theological intolerance has not yet died out in hospital management. We are, however, constrained to admit that in most instances it is sufficient to call attention to conduct of this kind to insure immediate reform, but the recent squabble at the German Hospital at Dalston shows once again to what lengths sectarian spirit can go in an institution which should be essentially neutral ground in respect of such matters. Medicine knows neither race nor creed; it takes no cognisance of the social antecedents of the sufferer, whose unique and sufficient claim to assistance and sympathy lies in the fact that he is suffering. The benefits of curative medicine fall, like the rain from heaven, upon the just and the unjust unlike. To impose any religious tests on the nurses of a hospital or similar institution is in reality to impose them on the inmates, and much valuable energy may be, and is, frittered away in acrimonious disputes, the only effect of which is to discredit the persons addicted thereto, and to militate against the harmonious management of the institution. It is strange that sectarianism which has been scotched, if not abolished, in our large general hospitals should have burst out with such violence at a comparatively small foreign hospital, but the fact is none the less greatly to be regretted, and the benefactors of the institution in question would be well advised if they took the matter vigorously in hand and peremptorily gave the disputants to understand that a hospital is a place for the medical treatment of the sick and not the *champ de bataille* of angry sectarians.

Clerical Lunacy Case.

The case of the Rev. Augustus F. Tollemache, which was recently disposed of by a Master in Lunacy and a special jury, raises the interesting question whether a man would rather have his character or his sanity besmudged. If his character be damaged, he may still have his freedom ; if his sanity be doubted, the liberty of the subject is in danger ; *ergo*, bad character *plus* liberty is preferable to the misfortune of disease *plus* restraint. Alas for these degenerate days ! when a defence takes refuge in a plea of drunkenness to escape a verdict of lunacy. The jury could not help finding the respondent insane and incapable of managing his own affairs. While the case was clear and the result obvious, it nevertheless opens up suggestions of difficulties that may possibly arise in other instances where the alleged insanity is not so patent to the lay mind. In medical practice the phrase *insane delusion* is current coin, so to speak, and the evidence of law courts contributes a wilderness of strange ideas which may be delusions, but are not always insane delusions. What of Mrs. Besant and her following ? What of Mr. Stead and his delusions regarding automatic writing ? What of the host of flesh and blood spiritualists who believe in whispers, table-turning, ghosts, &c. ? Evidence in this direction was led in the case of Mr. Tollemache, but it was beside the question at issue, and quite unnecessary, considering the proof of an indisputable kind that lay ready to hand, viz., his detention in an asylum, and the evidence of Drs. Bailey, Savage, and Maudsley. This case is another illustration of the fact that our lunacy statutes are framed in the interest of the legal profession.

Insanity in Ireland.

The Inspectors of Lunacy in Ireland have distinguished themselves more than usual by their report recently issued. A great deal of space is taken up with the question of tea as a cause direct or indirect of insanity, and much is made of female weakness, and the boiling teapot which frees so much tannin induces dyspepsia or worse, causes " nerves," and ultimately insanity. Not only do the inspectors, but many medical superintendents dwell gravely on this subject in their annual reports. It is an old idea revived ; but how much more is being made of the evils of " boiled tea " drinking than we have ever heard before ! and the question is whether mere tea infusions of infirm quality are much better, and whether starvation and other causes of malnutrition are not as much to blame as " boiled tea." The report emphasises what has been brought out already by statistics, that one cause of the increase of insanity in Ireland is that the strong emigrate and the weak are left behind. Lastly, agricultural depression, mental strain and anxiety are credited, and probably rightly so, with the production of insanity.

The Revival of Earrings.

Of all the fantastic vagaries of fashion none appear more in the light of a reversion to the habits of aboriginal ancestors than the wearing of earrings as ornaments. The custom, among the middle and upper classes at any rate, has fallen into abeyance. Whereas twenty years ago every woman had her ears pierced and wore earrings, now it is the exception, and these barbaric ornaments are now rarely seen except in a few matrons who cling to the traditions of their youth. So far as one can see, the fashion is indefensible. It is just one shade less ghastly, because less conspicuous, than the nose-rings worn by some Indian and other native tribes. It offends against every natural canon of adornment. One can only hope that this barbarous addition to sexual ornamentation may, like the late threatened invasion of crinoline, fade away into nothingness beneath the strong arm of ridicule. Women who are anxious to advance the great modern movement of female emancipation will do well to frame a sumptuary code in accordance with ordinary rules of hygiene and common sense.

The General Council of Safe Medicine.

The appeal case of the ex-miner who aspired to practice on the strength of a diploma granted by the " General Council of Safe Medicines, Limited " was last week dismissed with costs. As readers may remember, the plaintiff Steel gave up coal-mining for the practice of medicine, and having armed himself with a diploma from the society mentioned, he started practice and signed certificates as " Joseph Steel, M.D., (B.C.)." The latter two letters in brackets were intended to signify Botanic College. The issue of documents signed in this way soon brought Mr. Steel under the attention of the local authorities. He was brought before the magistrates and fined £10 for contravention of the Medical Acts. His subsequent appeal against that decision has, of course, been refused in the higher courts. A large field is open to the operations of limited companies, but it is to be devoutly hoped that it will never include the granting of bogus degrees.

Charge of Manslaughter against an Asylum Attendant.

At the Glasgow Circuit Court a few days ago, an attendant in the Burgh Asylum, Paisley, was charged with the death of a male patient who had only been a few days in the Asylum. Stott, the man so charged, was the night attendant, and with him giving assistance was a male patient who had been known to give a black eye on more than one occasion, and was regarded as irritable, and not to be depended on. The fact that such a patient was on night duty, though no proof, circumstantial or otherwise, of his having attacked deceased was forthcoming, saved Stott. The jury found the charge not proven, but they reflected seriously on the management of the Asylum for allowing such a patient to be told off for such responsible work as night duty. It is not creditable to the Asylum, or those responsible for its management, and it excites unnecessarily public suspicion about asylums which is more easily raised than allayed.

Accommodation Shelters for Exposed Persons.

One of the most useful and necessary provisions of the Public Health (London) Act, of 1891, is that which allows the local authorities to provide temporary accommodation for families who have been exposed to infection. A house is set apart, and serves as a kind of probationary shelter for the inmates of dwellings where "a dangerous infectious disease has occurred." The Commissioners of Sewers have provided a shelter of the kind for the City of London division of the metropolis. Quite lately, we note that several persons were admitted to the shelter while their own houses were undergoing disinfection. This very salutary and reasonable preventive measure might well be adopted throughout the kingdom. It is interesting to observe that, notwithstanding the enormous day population of the City proper, the registration returns show the small rate of eight deaths and ten births. The residency of this district, as most readers are aware, is practically restricted to housekeepers and a few tradespeople.

Sad Death of a Medical Man.

The sad death of Dr. A. H. Twining, Medical Officer of Health to the Union of Kingsbridge, Devon, has removed a most popular practitioner from among a large circle of patients and friends. His death was the result of an accident caused by the foolishness of two boys. He was being driven along a country road in company with his assistant, when, in accordance with a May Day custom prevailing in the district, the boys from over a hedge squirted water at the horse with a syringe, causing the animal to bolt. The trap was smashed and the occupants were thrown into the road. The assistant and the coachman escaped with slight injuries, but Dr. Twining received a compound fracture of the leg and other injuries. He was removed to the South Devon and East Cornwall Hospital at Plymouth, where, on the 6th instant, it was found necessary to amputate his leg. We much regret to say, however, that he died on the following day from the shock and the injuries he had received. Old St. Bartholomew's men of twenty years' standing will remember that Dr. Twining was one of the best "forwards" in the football team. As a student he was very popular, and the news of his sad end will awaken many memories among those with whom his student days were passed.

The Lunacy Inquiry at Lewisham.

The Queen's Bench action which has been brought against Dr. Duke and Dr. Beaumont, the medical officers of the Lewisham Workhouse, by Mr. J. M. Williams will, we believe, shortly come on for trial. Against the former damages of £1,000 are claimed, and against the latter £1,500. It will be remembered that the circumstances of the case, one of alleged wrongful detention in the Canehill Lunatic Asylum, were fully inquired into by the Local Government Board, and the result of the protracted investigation was that the Board approved of the conduct of the medical men concerned. Drs. Duke and Beaumont have now very properly asked the Guardians of the Union to be responsible for costs in the action. This is a perfectly reasonable request in view of the fact that the two medical officers were professionally in the service of the Board at the time the alleged erroneous certificate was signed, and we trust that at the next meeting of the Board a favourable answer will be given.

The Oldest Medical Man in Europe.

The claim that Dr. De Boissy, of Havre, who celebrated his one hundred and first birthday on April 28th last, is the oldest medical man in Europe, is now disputed. A correspondent to the *Western Mail* points out that a neighbour of his, a Dr. Salmon, residing near Cowbridge, Glamorgan, attained his one hundred and fourth birthday on the 16th of March last. It may, however, be observed that there is no name of any medical man whose qualifications would correspond with this age, either in the "Medical Register" or the "Medical Directory." Nevertheless, the profession in England may be proud to know that one of their number has now the reputation of having attained so patriarchal an age, assuming that the correspondent of our contemporary is correct in his facts. We should like, however, to have some confirmation of this statement. Meanwhile it would appear that Dr. De Boissy is still in the active practice of his profession, a record which has probably never before been reached.

A Remedy for "Viewing the Body."

The much disputed custom of requiring the jury "to view the body" at inquests has at last attracted the notice of a Member of Parliament. Captain Grice-Hutchinson has introduced a bill which proposes to do away with the duty at present incumbent on a jury of personally inspecting the remains of the deceased person into whose death an inquiry is being held. Safeguards, however, are included in the bill to ensure identification, either by persons acquainted with the deceased, or by a medical officer. Probably, owing to the turmoil of party politics, there will not be much opportunity for the bill to make much progress in the present Parliament; nevertheless, there is everything to be said in favour of such a measure, and it would be almost certain to meet with the approval of both sides of the House of Commons whenever it was brought forward.

Election of Examiners of the Royal College of Surgeons in Ireland.

The annual election of the Courts of Examiners will take place on the 17th, and for the Anatomy-Surgery division of the Court there is considerable competition. Mr. W. Thomson resigns his seat in order to seek the Vice-Presidency of the College next June. The other three members of the Court—Messrs. Barton, W. Stoker, and Sir Wm. Stokes—offer themselves for re-election. Messrs. Burgess, Chance, T. Myles, J. Dallas Pratt, Tobin, and J. H. Scott, also offer their services. In the other Courts of Examiners no very material change seems likely.

Election of the Council of the Royal College of Surgeons in Ireland.

The annual election for President, Vice-President, Secretary of the College, and Councillors will take place on the first Monday in June. Mr. Hamilton retires from the presidential chair on the completion of his second year of office, and he will be succeeded by the

Vice-President, Mr. Thornley Stoker. Mr. W. Thomson seeks the Vice-Presidency, and will probably be unopposed. Sir Charles Cameron will also probably retain the Secretaryship of the College without a contest. In the Council a vacancy is created by the retirement of Mr. Myles, who seeks a Surgical Examinership. There will also be several competitors from outside the present Council. Dr. Archibald H. Jacob has intimated his candidature, and we believe that Mr. Ormesby, Dr. Auchinleck, and other Fellows will offer themselves to the electors.

On the 10th ult., the female students of the Sanitary Institute, London, were presented with their certificates by H.R.H. the Duchess of Albany. Thirty-eight candidates were awarded certificates by the examiners, as against 17 in the corresponding term of 1893. The meeting was addressed by Sir Douglas Galton, K.C.B., who occupied the chair.

Their Royal Highnesses the Duke and Duchess of York have definitely promised to visit Leeds in the autumn to open the new Medical Department building at the Yorkshire College.

◆

Scotland.

[FROM OUR OWN CORRESPONDENTS.]

The Sequel to a Case of Alleged Malpraxis.—Not many weeks ago we noted that Dr. Allan, of Lasswade, near Edinburgh, had been mulcted by a jury of £50 for alleged malpraxis, the decision of the jury being directly against the judges' summing up, and contrary to the expectation of all concerned. In a local print describing the school board election held there a short time ago and for which the doctor was a candidate, the statement occurs: "The election was taken as an occasion for marking public sympathy with him in the surprising result of his recent law-suit." The result proves that public sympathy was on the doctor's side, as he has been elected by a large majority over everyone else, and is now Chairman of the Board. As Dr. Allan's expenses in the late trial have largely exceeded the £50, it will be some consolation to him in mind, though not in pocket, to find that the people of the district do not acquiesce in the verdict recorded against him.

University Examinations.—Some ugly rumours about the fairness of the examiners in one of the subjects for a professional examination have been hinted at in one of the Edinburgh papers. It is doubtful if there is any truth in them, but they go so far as to assert that a professor has been censured by the Senatus for rejecting so many candidates, and that this same professor, having ploughed his co-examiner's medallist, the co-examiner, an extra-mural lecturer, retaliated by ploughing the professor's medallist.

The Airdrie Hospital Scandal.—The charge has been withdrawn against the matron of the Airdrie Fever Hospital. From evidence adduced at the trial there were only two nurses altogether to do the cooking, house work, nursing, &c., neither of whom were properly trained nurses. The scandal, indeed, did not rest so much on the head of the matron and head nurse of the establishment as on the management who permitted such undermanning.

The Edinburgh Medico-Chirurgical Society are to hold a special meeting this week to consider the subject of Massage from Medical, Surgical, and Gynæcological standpoints.

The Royal Hospital for Sick Children, Glasgow.—Owing to the increasing attendance at the dispensary in connection with this hospital, the directors have found it necessary to add to the number of the staff. At their last meeting they appointed Dr. R. Barclay Ness and Dr. R. Mackenzie Anderson as Extra Honorary Physicians, and Dr. James H. Nicoll as Extra Honorary Surgeon.

Paisley—Gift of a Nurses' Home.—Intimation of another magnificent gift to Paisley has been made. For some time past the directors of the Paisley Infirmary have had under consideration the accommodation to be provided for their nursing staff in the new Infirmary to be erected at Egypt Park, towards the erection of which the trustees of the late Mr. Barbour, M.P., recently gifted £15,000. The directors were anxious to have the nurses' accommodation in a building separate from the infirmary, but on account of the serious expense such an arrangement would incur, it was feared that the proposal would have to be departed from. At a recent meeting, however, of the directors, a letter was received from Mr. Peter Coats, Paisley, offering to build, at his own expense, a detached home for nurses in connection with the new infirmary at Egypt Park. The Home is to be thoroughly detached from the main building. There will be separate rooms for all the nurses, and there will be a large general room to be used as a sitting-room, whilst otherwise the home is to be fitted up with every modern convenience regardless of cost. Mr. Peter Coats will himself undertake the whole arrangement of the plan and general equipment of the building, and on its completion he will formally hand over the home to the infirmary directors. The accommodation to be provided will be for a staff of about forty nurses. It is expected that the cost will be about £10,000.

Correspondence.

COUNTER-PRESCRIBING.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—I thoroughly agree with you in your condemnation of the proposal of so honoured a member of the profession as Sir Benjamin Richardson to legalise "counter-prescribers." There is a wide difference between tacitly permitting and legalising. Were counter-prescribing licenced by law the general public would rapidly recognise such chemists as doctors recognised and authorised to prescribe by a duly constituted authority. The public cannot reasonably be expected to appreciate the difference between licensed doctors of a higher and lower grade. With all respect to Sir Benjamin's opinion, I sincerely trust that counter-prescribing, or prescribing anywhere, will never be authorised by the law, unless the prescriber be a fully qualified and responsible medical practitioner, in the interests alike of the patients, the profession, and the public. How can a man prescribe intelligently unless he have a knowledge of disease as well as of physic?

I am, Sir, yours, &c.,

Norman Kerr.

42 Grove Road, Regent's Park, London, N.W.
10th May, 1894.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—There is no doubt but that during the last few years there has been a great increase in the prescribing by pharmaceutical chemists of the kind for which Sir B. W. Richardson is advocating some special conditions. This is due chiefly to the fact that the diploma, L.R.C.P., M.R.C.S., has been taken by a great number of those entering general practice, in preference to the L.S.A. The former does not provide for the open surgery which really met the wants of the public in respect to those lesser ailments for which the pharmaceutical chemist prescribes across the counter. Although the College of Physicians may have imagined that the status of the general practitioner was being raised by discouraging the open surgery, it must be clear that if the result has been to drive the public into chemists' shops no great advantage either to the profession or the public has been gained. It would seem in every way far more desirable that if prescribing of the kind referred to by Sir B. W. Richardson is a further necessity, it should be in the hands of those qualified by such a diploma as the L.S.A., than of unqualified chemists. Considering the character of the Pharmaceutical Society's examinations and the time required for preparing for them, it would be far better that encouragement should be given to those who are looking forward to counter-prescribing as a part of their life's work to devote themselves to the wider studies required for the L.S.A.

In this country it seems impossible to change from the old-fashioned system of general practice and open surgeries for the more distinct separation which exists on the Continent between the doctor and the pharmacist. Such being the case, the solution of the difficulty is to be found only in the direction indicated.

I am, Sir, yours, &c.,
R. L.

◆

INTERMITTENT CONTRACTIONS OF UTERINE MYOMATA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Kindly allow me to correct a mistake in your report of my remarks on the discussion of my paper read before the Obstetrical Society of London, and published in your last issue. In it I appear to say, in answer to Dr. Cullingworth, that I could not say whether it was extra- or intra-uterine pregnancy; whereas I laid stress on the advantages these contractions gave us of saying whether a fœtus was inside the uterus or outside. May I also point out an error into which some have fallen, as may be gathered from some of the other remarks made after my paper, namely, that I have nowhere said we could *see* the uterus contract, nor that the contractions were rhythmical. I have called them "intermittent."

I am, Sir, yours, &c.,
J. Braxton Hicks.

34 George Street, Hanover Square, W.,

◆

THE LATINITY OF PRESCRIPTIONS.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—Kindly give me space to call attention to the difference of opinion which exists (where none should exist) as to the correctness of writing "aquam" or "aquæ" when followed by the phrase, "Ad uncias octo." I maintain it should be written, "aquæ." The ingredients of a prescription are expressed in the genitive case, "governed" by the quantities which are expressed in the accusative. There is no reason why an exception should be made, and the whole construction changed simply because we find it difficult to express in Latin the ounces, drachms, minims, &c., which go to make up the mixture, and we use instead the substantive phrase, "Ad uncias octo," which is an abbreviation of the longer one, "Quantum sufficiate at fianto unciæ octo." I think it is a reflection on the profession that there should be a difference of opinion on such a subject.

I am, Sir, yours, &c.,
M. A. Donnelly, F.R.C.S.I.

May 4th, 1894.

◆

RAGWORT IN THE TREATMENT OF DISORDERS OF MENSTRUATION.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—By re-introducing ragwort into medical practice, Dr. Murrell (Medical Press, April 25, 1894) has done a real service to the profession. It is, difficult to understand how the plant became so neglected; at no time was it wholly lost sight of. Dr. Purdon, in January, 1882, recommended its use for *pruritus* in the *Practitioner*.

The family *Senecio*, Linn., is said to be named from *senex*, on account of its silvery capitate seed-down resembling the grey hairs of an old man.

Like all the *Compositæ* N.O. it is widely distributed. *S. aureus* or ragwort is said by Schœpf to be a favourite vulnerary with the American Indians. *S. Saracenicus* or broad-leaved groundsel, was used by the Saracens to staunch bleeding and to heal sores.

S. Jacobæa, or common ragwort, was a favourite drug of Boerhaave, who prescribed it as an aromatic tonic. A writer in the *Medical Gazette*, Vol. II., 1840-41, proposed its use as a remedy for gonorrhœa. Gray ascribes medicinal properties to the following varieties:—*S. Caculiaster*, *S. Doria*, *S. Doronicum*, *S. Jacobæa*, *S. Sarracenicus*, *S. Tomentosus*, and *S. Vulgaris*. He ascribes powerful anthelmintic properties to *S. Tomertosus*, and considers the *S. Doronicum* useful as an anti-asthmatic.

Of the *S. Jacobæa* Dr. Hooper writes:—"A decoction is said to have been of infinite service in the cure of epidemic dysentery. A poultice made of fresh leaves is said to have surprising effect in removing pains of the joints, and to remove the sciatica, or hip gout, in two or three applications, when ever so violent. The root is of an healing, and a stringent nature. A decoction of it is good for wounds and bruises."

"Eclectics" consider it a reliable and useful emmenagogue, and use it not only to stimulate the function, but to regulate it when in excess or otherwise deranged.

As a domestic remedy it has been used as an emetic, to stop spitting of blood, to stop convulsions in children, and for the great undefined class of ailments known as "liver complaints."

The plant is not devoid of toxic properties, as shown by M. Guilloeut (*a*). In 1831 Signor Pinazzi drew attention to the influence exerted by the drug on the cerebro-spinal system. Thus we see that notwithstanding the exclusion of the drug from the list of therapeutic remedies given in the principal works on materia-medica for the past fifty years there is evidence that it is worthy of a fair trial. It is an indigenous plant, and comes to our notice with the approval of centuries: included in the "Durham Glossary of Worts," in the "Herbarium" of the Saxon leeches, where the *S. Vulgaris* is recommended for (1) Wounds though they be old, (2) For blows of iron, (3) For foot disease, (4) For sore of loins.

Throughout the leech-books, Senecio finds a place in the majority of the prescriptions. With Gerarde it was a prime favourite. He writes: "It is commended by the later Physitians to bee good for greene wounds and old filthy ulcers which are not scored, mundified, and made cleane; it also healeth them with the juyce heereof tempered with honey and May Butter, and boiled together into the form of an ungent or salve. It is much commended, and not without cause, to helpe old aches and paines in the armes, hips, and legs, boiled in hogs' grease to the form of an ointment. Moreover, the decoction hereof gargarised is much set by as a remedy against swellings and impostumations of the throat, which it wasteth away and thoroughly healeth. The leaves stamped very small, and boiled with some hogs' grease into the konsumption of the juyce, adding thereto in the end of the boyling, a little Masticke and Olibanum, and then strained taketh away the old ache in the hucle bones called Sciatica. The Ægyptians (saith Prosper Alpinus) use Sea Ragwort for many things, for they commend the decoction made with the leaves thereof against the stone in the kidnies and bladder, as also to helpe the old obstructions in the inward parts, but principally those of the wombe; as also the coldnesse, strangulation, barrennesse, inflation thereof, and it also brings downe the intercepted courses, wherefore women troubled with the mother are much used by baths made of the leaves and floures hereof."

Dr. Francis P. Porcher (*b*) states that, "The plant is used in fevers in Maryland as a substitute for quinine."

Of the seventy-five varieties of Senecio, mentioned by Gregory, Hooker gives fifteen as commonly found in our fields.

I am, Sir, yours, &c.,
George Foy.

7 Cavendish Row, Dublin,
April 28th, 1894.

◆

UNIQUE CONDITION OF HERNIA.

TO THE EDITOR OF THE MEDICAL PRESS AND CIRCULAR.

Sir,—In the interesting account of Mr. Anderson's case of hernia, under the heading of "Operating Theatres," in to-day's issue of the Medical Press and Circular, the following statement occurs: "The hernia, he pointed out, was sacless and direct; here was a portion of gut almost entirely uncovered by peritoneum passing through the external abdominal ring; it was hard, he thought, to say what portion of intestine this represented; from its great thickness, it could only have been the large intestine, and structurally it bore a close resemblance to rectum, but it might have been a misplaced sigmoid flexure or even cæcum." In connection with the above, I should like to suggest, if I may, that the whole of the description would

---

(*a*) "Des effets toxiques du Senecio." 4to. Paris, 1883.
(*b*) "Southern Fields and Forests." Charleston. 1863.

apply to a hernia of the bladder, and further that the correctness of this view might be determined even now by passing a bougie into the bladder and finding out whether the hernia is connected with that viscus or not. The occurrence, a protrusion of the bladder uncovered with peritoneum, is not quite so uncommon as one is naturally inclined to imagine.

I am, Sir, yours, &c.,
Edward Cotterell.

Laboratory Notes.

TWO NEW FOODS FOR INFANTS.

We received some time since from the well-known firm of Messrs. Allen and Hanburys, samples of two new infants' foods, and our report has been delayed by the fact that the importance of the subject necessitated a specially careful investigation.

Sample No. 1 is a "first food for infants," that is to say, for infants under three or four months of age. This white, dry, non-hygroscopic powder is prepared from carefully-selected cows' milk of approved quality, the proportions of the various constituents being modified by subtraction of the excess of casein and various additions, so as to conform to the ideal standard of infant nutrition. The resulting product is concentrated *in vacuo* and sterilised, and is finally put up in securely closed boxes, ready for use. Analysis shows No. 1 food to contain between 65 and 66 per cent. of carbohydrates, with rather over 14 per cent. of nitrogenous principles and rather less than 13½ per cent. of fat (cream, &c.). It is rich in mineral constituents (including phosphates) of which it contains about 5 per cent. Much of the sugar is lactose and the rest maltose, and with it is associated the diastase, to which malt owes its digestive properties. The reaction for starch gave negative results.

The result of the analysis of No. 2, "Mother's Milk Food" (for infants up to seven months of age) differs from the preceding only in an increase in the proportion of maltose and dextrine, with a corresponding decrease in lactose.

The taste of both foods is distinctly agreeable and inviting. The question of infant-feeding is one which is acquiring daily increasing importance, and the problem can only be satisfactorily solved by a firm whose reputation is a sufficient guarantee of conscientiousness of manufacture. In no department of commercial enterprise is there greater scope for unscrupulous manipulation, and the purchaser is necessarily more or less at the mercy of the producer. For this reason we have given the matter particular attention. Messrs. Allen and Hanburys may, we feel sure, be relied upon to maintain these foods at their highest possible standard of excellence, and with the results of our investigation before us, we have no hesitation in recommending these goods as being in every respect admirably adapted for their purpose. They are, physiologically, complete foods, needing only the addition of hot water to make them ready for use. In these days, when the bogey of tuberculosis in milk is stalking through the land, and the same nutrient fluid is accused of harbouring the germs of almost every specific infectious fever, the possibility of obtaining a food which, in addition to being constant in composition and of ascertained nutritive value, is free from any suspicion of being the vehicle of disease, will gladden the hearts and calm the apprehensions of parents.

SWEET ESSENCE OF RENNET.

We have been afforded an opportunity of examining the Sweet Essence of Rennet prepared by MacMaster and Hodgson, of Dublin, according to their well-known formula. The comparison of this preparation with the ordinary acid essences which occupy the market is very favourable to it, as it contains much more of the valuable peptones, and in a form much more stable than most such preparations. Without at all depreciating the peptonising powders which have established such a reputation in digestive ailments we believe that they have by no means unseated from popular favour the Sweet Essence for use in suitable cases.

THE MEDICAL DEFENCE UNION.

A special general meeting of the Medical Defence Union was held on May 8th, at 20 Hanover Square. The meeting was very largely attended, the chair being taken by Mr. V. Horsley, the President of the Union. Early in the proceedings, Dr. Walsh moved the exclusion of reporters and strangers, but on a division this was lost.

The Chairman made a statement that it would not be in the power of the meeting to discuss the case of Bloxham *v.* Collie as matters might be mentioned which would be of value to Mr. Bloxham in the action he was bringing against the Union, but it would be in order to ask questions concerning how the case came to be taken up, but no information would be given as to the exceptional circumstances. The Chairman also stated that meetings would be held in Manchester, Birmingham, and Bristol, and that the Council were prepared to thoroughly go into the question of necessary alterations in the bye-laws. The responsibility of the Council in the case of Collie *v.* Bloxham ceased when the vote of censure was rejected at the annual meeting of 1894. Dr. Bloxham's action against the Union for acting *ultra vires* was rejected by Mr. Justice Chitty. His decision, however, was not upheld by the Judges of Appeal, who ruled that the Council ought first to have written to Dr. Bloxham before taking up Dr. Collie's case. Upon this point the Union accepted judgment.

Numerous questions were then asked. The President stated that arbitration had been offered Dr. Bloxham by Dr. Collie, and this statement was made on the authority of Dr. Collie's solicitor. He also said their solicitor had offered arbitration during or after the appeal case. Dr. Bloxham, who was present, denied both these statements, and said arbitration had never been offered him either by Dr. Collie or by the Council.

Questions were asked in reference to the resolution unanimously passed at the annual meeting of 1893, that it was inadvisable to take up cases between medical men. It appeared that the Council in giving effect to this had added the words except under special circumstances, but attention was drawn to the fact that no mention was made of these words in this year's annual report, although they very seriously altered the resolution.

Dr. Chaldecott moved: "That this meeting calls upon the Council, even at this late period, to endeavour to settle pending litigation out of court."

After some discussion, the Chairman ruled the discussion out of order, but allowed the resolution. Later on, however, when a request was made to take the opinion of the meeting, Mr. Horsley ruled the resolution out of order.

Dr. Leslie Phillips made a personal explanation regarding a statement made by the President in a correspondence which had been published at the back of the summons calling the meeting. In consequence of this explanation, Mr. Horsley withdrew the statement in question and apologised to Dr. Phillips.

The meeting ended by an adjournment *sine die.*

◆

Royal College of Surgeons in Ireland—Annual Elections.

A meeting of the President, Vice-President, and Council will be held on Thursday, May 17th, to elect Examiners. A meeting of the Fellows will be held on Saturday, June 2nd, to receive the annual report of the Council. A meeting of Fellows will also be held on Monday, June 4th, to elect a President, Vice-President, Council, and Secretary for the ensuing year.

Medical Temperance Association.

The eighteenth annual meeting will be held at the London Temperance Hospital, Hampstead Road, N.W., on Tuesday next, May 22nd, at 4.30 p.m. The annual report and balance sheet will be presented and the officers for 1894-5 installed, after which papers will be read on The Attitude of the Medical Profession with Regard to the Use of Alcoholic Liquors. (1) As it has been, by Dr. Norman Kerr; (2) As it is, by Dr. J. J. Ridge; (3) As it should be, by Prof. Victor Horsley. Medical visitors are especially invited.

Notices to Correspondents, Short Letters, &c.

☞ **Correspondents** requiring a reply in this column are particularly requested to make use of a *distinctive signature or initials*, and avoid the practice of signing themselves "Reader," "Subscriber," "Old Subscriber," &c. Much confusion will be spared by attention to this rule.

Local Reports and News.—Correspondents desirous of drawing attention to these are requested kindly to mark the newspapers when sending them to the Editor

Original Articles or **Letters** intended for publication should be written on one side of the paper only, and must be authenticated with the name and address of the writer, not necessarily for publication, but as evidence of identity.

ROYAL MEDICAL BENEVOLENT COLLEGE.

The annual general meeting will be held on the 31st inst for the purpose of electing the president, vice-president, and officers for the ensuing year, and for the purpose of passing a new bye-law. Full particulars will be found on reference to our advertising columns.

Mr. Stanford (Ryde).—There is no club in London which is exclusively confined to medical men. Some few years ago one of the kind called "The Galen Club" was started in Sackville Street, Piccadilly, but it was not long in existence. Just before it came to an end one of its members made an end of himself by shooting himself with a revolver in the lavatory of the club. There was a large financial loss on the working of the scheme.

M. P. S.—We declined the advertisement, not because it was *per se* objectionable, but because it did not appear to us to be suitable for even the advertising columns of a medical journal.

M.D.Cantab.—There is no published report so far as we know as yet. Our correspondent will have to exercise his patience, in the same way as other persons, in the matter.

Anon.—We see nothing strange or shocking in there being an "hon. consulting gynæcologist" to the "Theatrical Mission." Indeed, one would suppose that his functions, if conscientiously fulfilled, must entail a fair share of work. The Mission evidently occupies itself with the physical, as well as the moral, well-being of its *protegées*, and it is not for us to say *cui bono!*

Dr. J. K. T.—The venture is certainly a praiseworthy one, but it is impossible to think that it will succeed. Everyone can but wish it success, even if they do not more actively show their appreciation of the efforts of the promoters.

Meetings of Societies, Lectures, &c.

WEDNESDAY, MAY 16TH.

Epidemiological Society of London (11 Chandos Street, Cavendish Square, W.).—At 8 p.m., Dr. Franklin Parsons: On the Distribution of the several Influenza Epidemics of Recent Years in England and Wales.

MONDAY, MAY 21ST.

St. John's Hospital for Skin Diseases (Leicester Square, W.C.).—At 6 p.m., Dr. Morgan Dockrell: Lecture on Eczema.

Vacancies.

Blackburn and East Lancashire Infirmary.—Junior House Surgeon. Salary £50 per annum, with board, washing, lodging, &c. Applications and testimonials to the Secretary on or before May 24th.

County Lunatic Asylum, Lancaster.—Assistant Medical Officer (unmarried) also to act as Pathologist. Salary £100 per annum, increasing to £200, with board, &c. Assistant Medical Officer (unmarried). Salary £100 per annum, with board, &c. Clinical Assistant. No salary, but board, &c. Dispenser (unmarried). Salary £50 per annum, with board, &c. Applications and testimonials to the Medical Superintendent.

Durham County Hospital.—House Surgeon. Salary £100 per annum, with board and lodging. Applications and testimonials to the Hon. Sec. by June 1st.

Lancaster Infirmary and Dispensary.—House Surgeon (unmarried). Salary £80 per annum, with residence, board, attendance, and washing. Applications and testimonials to the Secretary on or before May 23rd.

Nottingham Borough Asylum.—Assistant Medical Officer (unmarried). Salary £100 per annum, with board, apartments, and washing. Applications and testimonials to the Medical Superintendent by 21st May.

Royal Cornwall Infirmary.—House Surgeon (unmarried). Salary £120 per annum, increasing to £150, with furnished apartments, &c. Applications and testimonials to the Secretary on or before May 21st.

The General Hospital, Birmingham.—Assistant House Surgeon. No salary, but residence, board, and washing provided. Applications and testimonials to the House Governor on or before May 26th.

Victoria University.—University College, Liverpool.—Medical School.—Applications are invited for the George Holt Chair of Pathology. Endowment £375 per annum, together with share of fees. Also the Derby Chair of Anatomy. Endowment £375 per annum, together with share of fees. Applications and testimonials to the Registrar on or before June 2nd.

Appointments

Harper, J., L.R.C.P.Lond., M.R.C.S., Consulting Surgeon to the North Devon Infirmary.

Haynes, S. W., M.B., &c., Honorary Anæsthetist to the Birmingham and Midland Eye Hospital.

Heywood, C. C., M.A., M.B., B.C.Cantab., M.R.C.S., L.R.C.P., Honorary Medical Officer to the Pendleton Branch Dispensary of the Salford Royal Hospital.

Jones, W. B., M.B., B.S.Lond., House Physician to the Great Northern Central Hospital, Holloway.

Keyworth, A. F., M.R.C.S.Eng., L.R.C.P., L.M.Irel., Medical Officer of Health to the Marple Urban Sanitary District.

Leslie, R. M., M.A., M.B.Ed., House Physician to the Hospital for Consumption and Diseases of the Chest, Brompton.

Macrae, J. F., M.B., C.M.Ed., Medical Officer to the Brighton and Preston School Board.

Parsons, G. G., L.R.C.P.Lond., M.R.C.S., House Surgeon to the Carnarvonshire and Anglesey Infirmary.

Piggott, F. C. H., M.D., M.R.C.S., Medical Officer of Health for the Teignmouth Urban Sanitary District.

Powne, L., M.R.C.S., Medical Officer for Cheriton Fitzpaine and Stockleigh English of the Credition Union.

Sandford, G. C., M.B., C.M.Ed., House Surgeon to the Royal Maternity and Simpson Memorial Hospital, Edinburgh.

Sayres, A. W. F., M.R.C.S.Eng., L.R.C.P.Lond., Medical Officer to the Wincanton Union Workhouse.

Slane, H. J., M.B., M.S.Ed., Medical Officer for the Nafferton Sanitary District of the Driffield Union.

Steegmann, E. J., M.B., B.S., M.R.C.S., L.R.C.P., House Physician to the Hospital for Consumption, Brompton.

Strickland, C. E., L.R.C.P.Irel., M.R.C.S., Medical Officer for the Park Sanitary District of the Sheffield Union.

Willoughby, W. G., M.D.Lond., L.R.C.P., M.R.C.S., D.P.H.Camb., Medical Officer of Health, Eastbourne.

Births.

O'Reilly.—May 5th, at Thurnby, Guildford, the wife of Surgeon-Lieutenant-Colonel J. O'Reilly, M.B., of a daughter.

Pierce.—May 7th, at The Retreat, York, the wife of Dr. Bedford Pierce, of a daughter.

Robertson.—May 6th, at Mill House, Adderbury, Banbury, the wife of James S. Robertson, M.R.C.S., &c., of a son.

Marriages.

Goodhue—Jones.—May 9th, at St. Marylebone Parish Church, Frederick Willliam Jervis Goodhue, B.A.Cantab., M.R.C.S.Eng., L.R.C.P.Lond., to Ethel Sydney Jones, youngest daughter of Sydney Jones, M.B.Lond., F.R.C.S., of 18 Wimpole Street, London.

McAllum—Wyman.—May 8th, at Christ Church, Morningside, Edinburgh, Stuart Gerald McAllum, M.D.Edin., to Edith Geraldine, youngest daughter of the late Frederick Frank Wyman, H.M.B.C. and J. P.

Deaths.

Bruce.—May 8th, at Colinswell House, Burntisland, Fifeshire, Henry Alexander Bruce, M.D., Principal Inspector General of H.M. Forces, aged 86.

Callan.—May 7th, at Roden Place, Dundalk, Joseph M. Callan, M.D., Coroner.

Enright.—May 1st, at his residence, 7 South Parade, Waterford, John F. Enright, M.D., R.N.

Hamel-Smith.—May 5th, at Port of Spain, Trinidad, W.I., Lionel Hamel Smith, M.R.C.S., L.R.C.P.Lond., aged 30.

Jones.—May 4th, at Chapel-en-le-Frith, Derbyshire, Theobald Edward Jones, L.R.C.P.Ed., L.F.P.S.Glasg., son of the late Walter Jones, of Dublin, aged 53.

Taylor.—May 6th, at 21 Canfield Gardens, South Hampstead, Charles Taylor, M.D., aged nearly 79.

Twining.—May 7th, at the South Devon and East Cornwall Hospital, Plymouth, from the effects of an accident, Alfred Hughes Twining, M.D., of Salcombe, aged 41.

Wilmot.—May 9th, at Richmond Hill, Bath, Emma, the beloved wife of Philip Mann Wilmot, M.D., aged 80.

NOTICE—Announcements of Births, Marriages, and Deaths in the families of Subscribers to this Journal are inserted free, and must reach the publishers not later than the Monday preceding publication.

INTESTINAL OBSTRUCTION.

CÆCUM OPENED IN THE MIDDLE LINE OF ABDOMEN, FOUR MONTHS LATER STRICTURE OF DESCENDING COLON RESECTED.—THREE WEEKS LATER ARTIFICIAL ANUS DISSECTED OUT AND HOLE IN CÆCUM SUTURED AND RETURNED INTO THE BELLY.—DEATH TEN MONTHS LATER.

By HERBERT W. ALLINGHAM, F.R.C.S.

WILLIAM C—, æt. 30, was admitted into the Great Northern Hospital, January 9th, 1893. No family history of cancer or phthisis—never had typhoid or resided in any foreign parts. For the last two years had suffered from constipation and about six months prior to this attack had had abdominal obstruction lasting for about a week, relieved by purgatives and enemata.

For the last ten days before admission he had not had an action of the bowels and had been vomiting constantly the last two days. On admission the abdomen was greatly distended, tympanitic—no tumour to be felt; great pain at times—nothing had passed by the rectum even after repeated enemata, no rectal stricture. Aspect abdominal. Tongue moist but furred, and he stated he had not taken anything for the last few days. As he continued to get worse, abdomen more distended and vomiting incessantly, on Jan. 11th he was taken into the operating theatre, the abdomen opened in the middle line below the umbilicus, the cæcum and small intestines were found to be enormously distended. The intestines were so stretched that I was afraid to very carefully explore the abdominal cavity for fear of bursting the guts. Accordingly the cæcum was well drawn into the wound into the belly-wall, opened, and a quantity of fæcal matter came away. After it was emptied it rapidly refilled again and again. When more than two quarts of liquid fæces had escaped, the opening in the cæcum was closed with pressure forceps. The cæcum was then thoroughly washed and returned into the abdomen and the part of the cæcum around the clip on the opening was carefully sutured to the edges of the abdominal wound about its lower part. The upper part of the belly wound being closed in the usual manner.

The patient passed a good night. The next day as the cæcum seemed well glued up to the belly wall and the cavity thoroughly blocked off by lymph, the clip on the opening in the cæcum was removed and the bowels from the opening acted quite freely affording great relief. From this time the patient made an uninterrupted recovery. The bowels acting daily by the artificial anus, nothing whatever passing by the rectum. He returned to his home at Southampton, February 13th. On May 29th, he returned to the hospital greatly improved in health; he was fat and looking well. The bowels acted daily by the artificial anus, in fact the fæces were constantly running away as is always the case when the cæcum is opened: on account of the liquid condition of the fæces at this part of the large intestine. He asked me if it was possible to cure him and I, having carefully explained all the risks, he consented to undergo the operation.

On May 31st I made an incision 5 inches long along the left linea semilunaris, meaning to carefully hunt through the sigmoid flexure and all the colon, to find the cause of the obstruction and remove it if possible. The abdomen being opened as I have said in the left semilunaris I introduced my hand into the abdomen, and commenced by passing the sigmoid flexure through my fingers. This being normal I continued my search up the descending colon and about its centre found a hard tight stricture. The gut above and below the stricture was secured by indiarubber tubes passed through the mesentery. A large piece of the gut and the stricture between the tubes (about 4 inches in length) was then excised. Several large mesenteric vessels were divided about the mesentery and were secured. The "V" shaped section in the mesentery was then united. The proximal and distal openings in the gut were carefully joined over a Mayo Robson's bobbin. The mucous membrane of the intestines being first sutured together as described by Mayo Robson, by silk sutures, and lastly the serous surfaces of the gut united with Lembert's sutures. The parts were then well cleaned and returned into the belly. The wound in the belly wall united in the usual way. A little opium was given him after the operation. The patient passed a good night. The temperature the next day was 99·8° and the patient vomited a little—abdomen not distended. The wound was dressed and covered with blue gauze and collodion which kept it sealed from contamination with any fæcal matter which came from the artificial anus. I may here say the artificial anus was well plugged with a sponge prior to the operation and was only removed on June 2nd, two days after the operation, and then a large motion passed by the artificial anus, the patient being kept on his right side so that motion might flow well away from the wound. After the bowels had acted the parts were cleaned and a fresh sponge replaced, so as to prevent any further action until the next day.

June 4th.—Four days after the operation flatus was passed by the rectum, and when the sponge was removed from the cæcal opening, no motion came away.

6th.—The patient complained of pain in the abdomen. An enema, 5oz. of olive oil, was given, and three hours later 1 pint of soap and water and small motion was passed.

9th.—The collodion and gauze was removed from the abdominal wound which was found healed; all the stitches were removed.

I may here state that the sponge in the artificial anus was daily removed to allow the bowels to act, and then a new one replaced. Flatus was constantly passed by the rectum, and a good amount of fæces at times.

13th.—When the bowels acted by the artificial anus the sponge that was placed there was lost. The house surgeon, Mr. Cooper, carefully examined the opening, but not feeling the sponge, concluded it had passed out with the fæces, and had been thrown away.

14th.—The patient was operated upon again to close the opening in the cæcum. First a sponge was placed in the opening to prevent any escape of fæces during the operation. An incision was then made through the skin around the opening. The incision being about ¼-inch from the orifice. The peritonial cavity opened, and so the opening in the cæcum freed from its attachment to the skin. The cæcum was then drawn well out of the abdomen, and the orifice with the small piece of skin attached, carefully cut away from the cæcum. The fresh opening in the cæcum was then sewn up, first the mucous membrane edges brought together, and the serous edges of the incision united with Lembert's sutures.

The gut was then well washed and returned into the abdomen, and the wound in the belly wall united in the usual way.

15th.—Little sick during the night, otherwise very well.

17th.—Three days after the last operation. The bowels acted freely after an enema, and in the motion was found the sponge which was lost from the artificial anus on the morning of June 13th.

This was extremely satisfactory, as it told me the part where the stricture had been resected was quite sound, and, moreover, very patent as to allow the sponge to pass through it.

21st.—All the abdominal sutures were removed. The wound being soundly healed. The bowels had been acting daily by the rectum.

In a few days' time he was allowed to get up, and left the hospital the end of June perfectly well in every way.

In the early part of August he rode on a bicycle from Southampton to the Great Northern Hospital, London, in a day, and assured the sisters of the ward he was perfectly well.

On September 18th he was again admitted into the Great Northern Hospital, as he said the last few days he had had pains in the abdomen and had been sick. On admission the abdomen was distended, and he was frequently sick. He was given small doses of castor oil, and later on the bowels acted, and he was more comfortable.

September 23rd the patient was very ill again; great abdominal pain and some vomiting.

September 24th, as he was about the same, I determined to explore again the part where the stricture had been resected, thinking that perhaps the gut had contracted at the seat of resection. Accordingly under an anæsthetic an incision was made parallel to the one about the left linea semilunaris, but a little inside it. So the abdomen was opened, and it was found that the peritoneum was studded with hard nodules, and that there were masses in the walls of the small intestines, and great thickening and nodulation of the mesentery generally. The part where the resection was done was perfect—no stricture or contraction whatever. Seeing there was nothing to be done, and believing the nodules to be cancerous, I closed the abdomen. The patient recovered from operation, and stayed in the hospital until October 13th, when against advice he was taken to his home at Southampton, and was placed under the care of Dr. Robert Walch, to whom I am greatly indebted for the post-mortem examination and the specimens. The patient died on November 9th. Ten months after the first operation.

For the arrangement of the specimens and microscopic examination I am indebted to Dr. Rolleston and Dr. Lee Dickinson.

Mr. Cooper, House Surgeon to the Great Northern, took infinite care of the after treatment of the patient, and to whom I am most grateful for his careful notes.

Specimens represent —

1. The resected stricture.
2. The resected artificial anus.
3. The sponge passed through the gut.
4. The intestines with multiple strictures.
5. The part showing the result of the resection—a small silk ligature remaining to indicate position of resection.
6. Scar showing where the cæcum was sewn up.

REPORT OF DR. ROLLESTON.

"I have now examined the stricture, I should think in five different pieces. The great mass of the growth is very well-formed fibrous tissue, in part there are most unmistakable appearances of sphenoidal-celled carcinoma, this is very rare in the intestine.

"There is so much inflammation and cicatrisation about the stricture that this fibrous increase forms the most noticeable feature in most of the sections. In fact, as I told you, I could not for a long time find any evidence of a malignant growth.

◆

THE INFECTIOUS DISEASES (NOTIFICATION) ACT,

AND ITS EFFECT IN THE LARGE TOWNS OF ENGLAND.

By D. BIDDLE, M.R.C.S. Eng.,
Fellow of the Royal Statistical Society.

THE following tables, which are now published for the first time, formed the basis of a letter which appeared in the *Times* of April 16th, and the explanatory matter is here reproduced:—

The 28 towns selected for the investigation are those for which the Registrar-General, in his "Annual Summaries," has given the needed information for 12 years, 1882-93. They comprise a population which in 1881 numbered 8,313,709, and in 1893 was estimated to amount to 9,713,228, or close upon ten millions. For convenience they are divided into three groups—Group I., without any system of notification of infectious diseases until after the passing of the Act of 1889, and including London and ten provincial towns—namely, Bristol, Wolverhampton, Birmingham, Liverpool, Sheffield, Hull, Plymouth, Brighton, Leeds, and Cardiff; Group II., which for many years prior to the passing of the Act was under what is known as the single or householder system of notification, and including three towns—Bradford, Norwich, and Nottingham; Group III., which for four years prior to the passing of the Act had been wholly under what is known as the dual system of notification, requiring the medical attendant not only to certify, but himself (as well as the householder) to notify, this being the system now embodied in the Act, and numbering 14 towns—Sunderland, Portsmouth, Newcastle, Salford, Manchester, Oldham, Leicester, Bolton, Blackburn, Derby, Preston, Huddersfield, Birkenhead, and Halifax. Seven of these last-mentioned towns were under the dual system at the beginning of the 12 years under consideration. We can, therefore, conveniently divide the 12 years into three periods of four years each—(1) 1882-85, during which Group I. was under no system of notification in regard to infectious diseases, but Group III. was partially and increasingly under the dual system; (2) 1886-89, during which Group I. still remained under no system, but Group III. was wholly under the dual system; (3) 1890-93, during which all the towns, except Leeds of Group I. and Nottingham of Group II., belonged to the same category, and were subject to the system embodied in the Notification Act. I am sorry to say that Leeds, which had bravely stood its ground for four years, and greatly benefited by so doing, has at length caved of by 25 votes to 21; but the Act does not come into force there until May of the present year. For our purpose, therefore, Leeds remains a pure virgin throughout, and Nottingham also serves to show what can be done by the single system, which was the system originally advocated by the Local Government Board, who might reasonably return to their former faith.

The figures given in the subjoined tables are far from dry, and would afford material for a brilliant statistical lecture if handled by a Galton or Booth. It is part of the case of the opponents of the dual system of notification that it places a barrier between the public and the profession, causing parents and others to delay calling in medical assistance, even where the case proves after all to be non-notifiable and even non-

TABLE I.—Table giving for the twenty-eight large towns of England and for the several specified groups, the mean annual death-rates under the particular heads for three periods of four years each, namely, 1882-5 and 1886-9 *before*, and 1890-3 *after*, the Notification Act was passed.

N.B.—Leeds remained to the close of the last period under no system of Notification, and Nottingham remained under the single system only.

* The area of Manchester was greatly increased in 1890, and its density lessened, hence improved figures.

infectious, so that the general death-rate is affected by it to a considerable degree beyond what is due to zymotic diseases. But in towns under the system a contest of influences is continually being waged, for not only is there the baneful effect produced by making the medical man responsible for a duty which does not rightfully devolve upon him, but there is also in operation the beneficial effect of what may be called sanitation proper, which received a tremendous impulse forward in 1875 under Lord Basing, then Mr. Sclater-Booth. All that we can well profess to show, therefore, is that the dual system checks the decline in the death-rates that would otherwise go on until some unknown limit was reached. Observe, then, how in the first of our three periods of four years the general death-rate of the ten provincial towns of Group I was only 0·60 (per 1,000 living) better than that of Group III—in fact, in prior years, before Group III was tainted at all by the dual system, its death-rate was superior to that of the ten provincial towns of Group I. But in the second period (1886-89), during which Group III was wholly under the system, the death-rate of the ten provincial towns of Group 1, which remained to the end of this period without any system of notification, was 1·44 below that of Group III, although both had declined. In the third period, when nearly the whole of Group I was tarred with the same brush as Group III, there was a reconvergence of the death-rates, for the ten provincial towns of Group I had a mean general death-rate only 0·47 lower than that of Group III, and in 1893 they actually returned to their original position of inferiority, having a death-rate 0·52 higher than Group III. During the last of the three periods Leeds, under no system of notification, had a mean general death-rate far below that of the ten provincial towns or Group I taken together (Leeds included)—namely, 21·8, as against 22·57—but in 1893 22·2, as against 22·52. Liverpool, which many years ago spent several thousand pounds in amassing valuable evidence by which it successfully opposed the dual system, was, nevertheless, one of the first to adopt the Notification Act, with the usual result. Its mean general death-rates for the three periods were as follows:—26·8, 25·3, 26·7, and in 1893, 27·2, absolutely the highest and most disreputable on the list, beating even Preston with its 26·3. So much for the effect of the dual system upon the death-rate from all causes!

Taking next the total zymotic death-rates, including those from non-notifiable infectious diseases as well as those from diseases which are notifiable, we find that the dual system of notification does nothing towards lessening the death-rate from zymotic diseases taken as a whole. Thus, taking London as an example, we find that between the first and second periods, when the metropolis was without any system of notification, but depended on sanitation proper, a saving of life took place equal to 410 per million per annum on zymotic affections alone. But when the Notification Act came into force, the saving of life in this respect terminated, and there was instead an actual loss of life equal to 30 per million per annum during the last period, and rising to 310 per million in 1893. It is also clear that the towns longest under the system are those which suffer most, Group III. exceeding Group I. in its total zymotic death-rate at every point, but especially in the second period, when their conditions as to notification and non-notification were most contrasted.

But, after all, the crucial test is in the effect produced upon the death-rate from notifiable diseases. Notification has no *raison d'être* unless it helps to stamp out these. Its utility otherwise is purely academic, and even in this respect extremely doubtful, when the long list of cases of mistaken diagnosis is taken into account. So far the natural history of disease has not been advanced one inch by notification; on the contrary, the latter has frequently put us on the wrong scent, and thus retarded progress. Taking then, the death-rates from notifiable zymotic diseases, we find that they were—in the first period (1882-5), for the 28 towns as a whole, 1·036; for Group I., 1·087 (London, 1·03; ten provincial towns, 1·183); for Group II., 0·761; and for Group III., 0·934. In the second period (1886-89), for the 28 towns as a whole, 0·775; for Group I., 0·751 (London, 0·71; ten provincial towns, 0·825); for Group II., 0·583; and for Group III., 0·906. In the third period (1890-93), for the 28 towns as a whole, 0·772; for Group I., 0·791 (London, 0·86; ten provincial towns, 0·661); for Group II., 0·630; and for Group III., 0·753. For 1893 by itself the notifiable zymotic death-rates were—for the 28 towns as a whole, 1·023; for Group I., 1·108 London, 1·32; ten provincial towns, 0·759); for Group II., 0·926; and for Group III., 0·788. If it were not for the grim nature of the subject, there would be abundant food for mirth here, and one could laugh one's loudest, for, only to take the effect on the death-rate from notifiable diseases of the 28 towns as a whole, what do we behold during the last four years, as the result of all the labour and expenditure (not only in notification, but in still more costly isolation), and as compensating the community for all the irksomeness attending on the system? A saving of three lives per million per annum on the average, ending, however, with a dead loss of 248 per million in 1893! Contrast this with the grand saving of 261 per million per annum which had been effected before Group I. succumbed to the Act, and this in regard to diseases which are now notifiable alone. What a sorry figure does London cut! Before it was invaded by notification, the saving of life effected in regard only to diseases now notifiable had been 320 per million per annum, but since, there has been an average loss of 150 per million per annum, terminating in 1893 with no fewer than 610 per million! Thus, up to the end of 1892, London had made no progress in stamping out infectious diseases of the notifiable kinds, and in 1893 the tendency became grievously retrogressive. How long is this state of things to continue? The prevalence of influenza had certainly no direct effect upon the "notifiable," or even the "total zymotic" death-rate, for the deaths from that fell disease were not included under any of the seven heads above enumerated, but had a special column devoted to them on account of the exceptional character of the epidemic.

The tables include the death-rates from the four chief notifiable diseases taken separately, but these need not be further explained, since it seems sufficient, for the purpose of establishing my contention, to have shown that on notifiable diseases as a class the Notification Act has had no effect whatever, except to render them more deadly. But I may just mention that London has made no progress except retrogressive in regard to either small-pox or scarlet fever, and that the death-rate from diphtheria has hugely increased since 1889. I earnestly commend the tables to the careful study of all sanitarians.

NOTES ON THE

THERAPEUTIC ACTION OF ORGANIC EXTRACTS.

By R. W. FELKIN, M.D., F.R.S.E.,
Lecturer on Tropical Diseases, Edinburgh.

In the Medical Press, page 410 (April 18, 1894) there is a paper entitled "Further Notes on the Therapeutic Action of Organic Extracts," by Dr. Charles Forbes. In it a paper of mine is referred to, and a misprint occurs which I should like to correct. My paper was read on the 8th of November, 1893, not on February 17th, 1894, and only an abstract of it was published in the February number of the *Edinburgh Medical Journal.* I make this correction because I think I may claim precedence for administering organic extracts (quite apart from thyroid extracts) by the mouth and by suppositories. Rectal injections were, I believe, made previous to my experiments, which began at the commencement of 1893, although I had previously worked at the subject, and used hypodermic injections long before this.

I have not yet administered orchitic extracts by the mouth, preferring, for obvious reasons, to employ suppositories or rectal injections of the fluid, or the extract placed in gelatine capsules and slipped into the bowel or vagina.

An abstract only of my paper was published, and I withheld for a time the publication of that part dealing with "morbid processes following masturbation," and also that part dealing with various complaints connected with the generative system caused by, *e.g.*, marital excess, masturbation, those morbid processes, induced by the use of "precautions," also the administration of the extracts in other cognate conditions. I wait awhile before publishing my results, which are in the main favourable to this class of cases.

I regret that it should be thought that I have at all tended to "add to the obscurity already preventing a comprehensive differentiation of these extracts," and I have to thank Dr. Forbes for calling attention to the apparent want of clearness in my paper. Had details of all the cases been given it would no doubt have been better, and I hope soon to remedy this defect.

May I refer for a moment to two cases of masturbation treated by organic extracts with reference to Dr. Forbes' suggestion (page 411). The first case was that of a young man, æt. 23, whose health was completely shattered by the habit. I gave him an orchitic suppository (B.W. and Co.) every other night for 14 days, then one once a week for six weeks. All his troubles ceased; he put on flesh, gaining 1st 10lb in two months; he could again follow his employment, and was able to relinquish the habit to which he had been addicted for five years. For the last six months he has only used one suppository a fortnight and remains well. He will now stop the extract.

The other case is that of a lady, æt. 28. She began the habit when eight years old, and has for the last ten years been a perfect martyr to it and its effects. I tried the orchitic suppositories in her case, but to my great disappointment she grew worse, and she had one or two sharp rises in temperature, and very severe attacks of giddiness. In despair I tried the suppositories of cerebral extract. She was at once calmed, and almost got over the habit. Instead of giving way often more than once a day she was able on the fourth week of the treatment to manage with only one failure. Since then, December, 1893, she has steadily improved, and now nine weeks have passed in comfort and without a relapse. A case like this is very encouraging, but it opens up the difficult question—Why did the orchitic extract fail here, and why did the cerebral extract succeed? I can only suggest in the meantime that in this case it was probably a central irritation induced the habit, and not any local cause, but of course there may be a more satisfactory solution of the problem.

I think it only right to mention here that with regard to orchitic and ovarian extracts I have found that their action is somewhat erratic, that is to say, that sometimes I have failed to improve a case with one preparation or with one supply of the preparation, whereas on trying a new preparation, or a new supply success has been obtained.

I do not at present attempt to explain how these organic extracts act, but as with regard to infectious diseases one looks forward to the time when prevention will be the rule of the day, so with the derangements of internal organs the administration of organic extracts will, I believe, in the future do much to prevent or to speedily cure disease. We know the action of the administration of thyroid in myxœdema, but we do not know why, as Dr. Branwell has so conclusively shown, it should cause improvement in psoriasis or in lupus, or, as Dr. Abraham has shown, in leprosy, but we may, I venture to think, surmise that besides possessing the definite and specific action which it undoubtedly does in myxœdema, the "internal secretion" of the glands or at any rate some substance obtained from it, exerts a marked influence on the organism.

Now, if this be the case in one instance, why not so in another? and although it may be right to expect that in time we shall find the exact use for the extracts, fluid or dried, of each internal organ—brain, marrow, spleen, liver, ovary, testicle, &c., yet in the meantime we are justified, it appears to me, in investigating the results of one or other of these extracts in more than one class of cases. The late Brown-Séquard pointed out the results of the hypodermic injection of cerebral and orchitic fluids in pseudohypertrophic paralysis and foreshadowed the possible results which might be obtained by such injections, showing that, although one might expect better results from the injection of cerebral extract in this disease, yet, as a matter of fact, better results were obtained by the injection of orchitic fluid. It is not yet explained why this should be the case.

To explain why I have used various extracts in the same class of cases, I may say that it is not always possible to have extracts, at any rate fluid extracts, of all the organs of the body at hand when wanted, nor is it possible to be able to investigate so large a field at once, so that during the first year of my experiments I kept to the extracts of two organs—the brain and the testicle. Since then, however, I have worked with others, and as I gain experience I hope to be able to differentiate more clearly the limits to which the administration of each extract should be kept. This, notwithstanding, I should not be at all surprised to find that there is *one* internal secretion, or I should, perhaps, rather say one definite element found in the various internal organs, which alone may in a wide range of diseases act with benefit. What that element is I have an idea, but only an idea, and cannot yet deal further with the subject.

Since the above was written I have seen a paper on Castration in Females, by Dr. C. H. F. Routh (Medical Press, page 435, April 25th, 1894) in which he also refers to my paper.

Further experience confirms what I have previously reported as to the advantage which may be obtained by the administration of the organic extracts after castration in women. I have recently had a case in which a woman who was suffering from intense irritability and nervous excitement, accompanied by delusions and hallucinations, has been apparently perfectly cured; but I refer to Dr. Routh's paper because of his remarks on eunuchs. In Africa there are various methods of castration in vogue, in one of which the whole of the testicle is not removed, and whilst the individual is incapable of procreation, yet he retains virile powers, and presents a totally different appearance to that of the man in whom both testicle and cords have been removed. This, I think, forcibly demonstrates the fact of an incidental secretion exerting no little influence upon the well-being of the organism.

◆

On the 17th inst., Dr. Gilbert Ward died at his residence, Bridge Street, Blyth, Northumberland, at the age of 90 years. He was nearly the oldest medical man in the kingdom.

Selected Prescriptions and Therapeutic Notes.

137.—Useful for Scabies:—

℞ Creolini, gr. viij;
Vaselini, ʒiss.

M. The affected parts to be rubbed thoroughly once a day.—V. de Lollis.

138.—A Good Injection for Leucorrhœa:—

℞ Pot. chloratis, ʒiij;
Tinct. opii, ʒijss;
Aq. picis, ʒix.

M. Two or three tablespoonfuls of this solution in a quart of hot water may be used as an injection morning and evening, to correct the odour of leucorrhœal discharges which ascompanies some cases of endometritis, polypus, fibrous growths, ulceration of the cervix uteri, and even simple vaginitis. The injection should last five or six minutes each time.—*Presse Med. Belg.*

139.—Application for Burns:—

℞ Lanolini, partes x;
Adipis benzoati, partes xx;
Aq. calais, partes xxx.

M. —Unna.

140.—For Neuralgic Dysmenorrhœa:—

℞ Ext. opii;
Ext. belladonnæ, āā gr. jss;
Quiniæ sulph, gr. xv;

M. Divide into twenty-five pills. One every three hours.—*Rivista Clinica e Terapeutica.*

PECULIAR CASE OF FOREIGN BODY IN FOREARM.

Under the care of T. H. Donovan, M.B., B.Ch., Edgeworthstown.

P. M., farm labourer, æt. 40, consulted me on the 10th inst. about a foreign body that had been for a very lengthened period in his forearm. The history of the case is as follows:—Seventeen years ago, whilst assisting at the nuptials of a friend, he was striking a cork into a whisky bottle with his open hand, when the neck gave way and inflicted a severe wound in his palm. He treated the injury himself. The wound healed rapidly, the cicatrix of which is situated about three-quarters of an inch above and one quarter of an inch interior to the pisiform bone. About a year afterwards he found his wrist painful on moving it. This inconvenience lasted for about a month, and he then resumed work. About a year afterwards, he found a "lump" appearing at the proximal side of wrist. As this gave him no trouble, he continued working, and has been doing farm work ever since. However, about six months ago, he commenced to find great pain on moving his middle and ring fingers, and on examining the condition of things, he came to a correct diagnosis. He waited until the 10th inst., before consulting anyone, living in the vain hope that his friend of seventeen years would "cut its way through." When I saw him, the foreign body was distinctly to be felt lying between the flexor sublimis tendons, about two inches above the wrist. Having rendered the parts aseptic, I cut down and found a piece of glass about one-sixth inch square, lying between the two pairs of flexor sublimis tendons, its sharp edges attached to the deeper pair. I removed it. The wound healed by first intention, and the patient still clings (in a more comfortable manner) to his very interesting souvenir.

Transactions of Societies.

THE HUNTERIAN SOCIETY.

MEETING HELD MAY 9TH.

The President, Mr. C. J. Symonds, F.R.C.S., in the Chair.

ADJOURNED DISCUSSION ON DIPHTHERIA.

Mr. St. Clair B. Shadwell said that he was Medical Officer of Health to one of the eastern suburbs, divided from London by the river Lea. The annual number of deaths from diphtheria had been few, and in 1870 and 1872 there had been no such deaths at all. Between 1873 and 1879 the number amounted to about 3 annually. From 1880 to 1886, (1880 being a memorable year in the history of the district, inasmuch as it was then that the present system of drainage was entered upon) the annual number of deaths averaged 10. In 1887 there was a sudden rise, equal to a death-rate of 1·5 per 1,000, and in 1888 of 1·7. Since that date the rate had gone down, and for some years it had been 0·6 per 1,000. The Medical Officer of Health for Plumstead held very strongly that the great cause of the spread was the ventilation of the sewers into the road. The speaker thought it was quite possible that water might sometimes serve as a vehicle, and referred to the case of a lad employed at one of the dairies, who contracted diphtheria, and was placed in a room, the floor of which had wide crevices, and beneath it was the water cistern. It was impossible to prove that the water was really contaminated, but the fact remained that seven other persons in that house caught the disease. The only domestic animal that appeared to him to have any share in disseminating the disease was the cat, and a few instances of this had come to his notice. Skilled opinion at present tended to regard bad smells as not having much to do with the causation of the disease. He then showed on the screen a rough plan of the district, pointing out how the disease had occurred in a particular street, and it looked really as if the system of drainage had something to do with its spread. In other parts of the district it had spread in the neighbourhood of certain schools, having been conveyed thither by one of the patients from the infected street. If anything was to be done to check the spread of the disease, there must be a definite understanding between the school and the sanitary authorities. Diphtheria might be conveyed a considerable distance, and he instanced a case in which it could be clearly traced from New York to Liverpool and further into the country.

Dr. Washbourn had never had the slightest difficulty in demonstrating the presence of the bacillus, and this in large numbers, in all recognised cases of diphtheria. The bacillus was only found in the membrane; it was, therefore, a local disease, for the bacillus never grew in the tissues or fluids of the body. The membrane which formed on the fauces was very different in appearance from that which formed in the trachea, and as it spread into the smaller bronchi it gradually changed into a thick exudation. Dr. Sidney Martin had been able to separate certain albumoses and organic acids which, when injected into rabbits, produced death, preceded by paralyses such as were met with in the human subject after diphtheria. Dr. Washbourn then described the method of making cultivations of the bacillus from the membrane. This was a very simple matter. A patch of membrane was washed with sterilised water, and then a piece was hooked off with sterilised platinum wire, and sown on the surface of some blood serum. The tube was put in an incubator, and within 12 hours a diagnosis could most certainly be made. If the case were one of diphtheria, there developed on the surface of the serum a number of large white colonies of the diphtheria bacillus; when a little of the culture was spread on a cover glass, dried, and stained with methyl blue, the bacillus could be seen with high power. It consisted of rods, clubbed at the ends and taking the stain irregularly. It had been assumed that the "pseudo-diphtheria bacillus" was only a modification of the ordinary diphtheria bacillus. In favour of this view was the fact that the ordinary virulent bacillus could be rendered non-virulent by certain methods of cultivation. In 45 children suffering from various diseases of the throat other than diphtheria, the pseudo-bacillus had been identified in 15, and the examination of the fauces of 49 healthy children showed it to be present in 26. It had been suggested that the non-virulent bacillus might undergo an increase of virulence in the presence of a certain inflammation, and this view would explain the occurrence of many outbreaks of the disease. Membranous exudations often occurred in scarlet-fever, but this was not diphtheria, for the bacillus could not be found, and clinically this exudation differed also, and was not followed by paralysis. Another class of cases were those of real diphtheria without membrane. He referred to the case of three brothers in the same house, all of whom were attacked with sore throat. The first two had simple redness of the fauces, but showed the diphtheria bacillus, and the third shortly afterwards had a typical attack of membranous diphtheria. As to the duration of infection: fourteen days after the disappearance of the membrane virulent bacilli had been found on the tonsils. One might get a membranous exudation in the throat of pigeons, which, though contagious, was not diphtheria.

Dr. **Hingston Fox** showed diagrams to illustrate the mortality from diphtheria during the past 35 years in London, as recorded by the Registrar-General. Starting with a death-rate of 284 per million in 1859 and subsequent years, a long period of quiescence followed between 1864 and 1882 (only 80 per million in 1872), since which there had been a rise, considerable in 1888 and 1889, and still more in 1892 and 1893, until last year the mortality reached 750 per million inhabitants. If diphtheria had an epidemic cycle, it must be one of long period. The mortality from scarlatina was altogether on a larger scale, attaining in epidemic years as in (1870) even 1,875 deaths per million. It bore no relation to the diphtheria death-rate, and had been low of recent years. Measles also bore no such relation: this disease showed a curious tendency to be prevalent in alternate years. Enteric fever was the only specific disease bearing an apparent relation to diphtheria, and this was one of inverse prevalence; during the recent epidemic the enteric curve had been depressed. The inverse relationship, in geographical occurrence, of these two diseases had been clearly shown. A second diagram displayed the seasonal prevalence of diphtheria which was, like scarlatina, increasing in the autumn and declining in January, only to a less marked extent. On the third chart, the distribution of cases over different ages and sexes was marked out, showing, of course, the selection mainly of the early years of life, and the slightly greater liability of females to be fatally affected. The gradual change in the disease, leading it to become more prevalent in towns and less exclusively in the country, its great variability, and association with apparently simple tonsillitis, and its having no constant skin rash, suggested that it was yet unstable, and had not developed to the stable position of other specific fevers.

Dr. **Glover Lyon** said that at one of the fever hospitals all cases of sore throat among the nurses or staff had been treated early by local applications during thirty-five years without one death. The mere number of deaths, to the extent of double that in former epidemics, did not prove that we were in a very much worse state, because the improved diagnosis must be taken into account. With regard to typhoid fever, it did not seem probable that there was any connection between the two. The extra exactness of diagnosis in typhoid fever, and the care in its treatment, had reduced its mortality.

Dr. F. J. **Smith** referred to three cases. He treated each with a different local application, and all had recovered.

Mr. **Thorp** had long used a combination of phenol, turpentine, and strong liquor ferri perchloridi locally.

Dr. **Walter Carr** asked whether a membrane in the throat proved not to be diphtheritic could be pronounced not infectious, and, therefore, in no need of isolation.

Dr. H. J. **Sequeira** said he had had experience at a fever hospital of three or four hundred cases. The mortality with or without treatment was between 30 and 35 per cent. The use of local treatment or not did not seem to make any difference.

Dr. **Arthur Davies** observed that the empirical method of treatment by attacking the membranes had a solid scientific basis, the bacillus being in the superficial part of the membrane.

Dr. **Goodall** said that if the larynx was implicated the case was one of diphtheria. It was good treatment to get rid of the membranes as fast as they could, applying the spray, or, better, washing out the mouth with a Higginson's syringe. He had never sent a child out under six weeks—after a bad attack much longer. He had never had a case sent back from the same house, though this was tolerably frequent in scarlet fever. Adults might go out at the end of a month, but should be warned against kissing their children.

Dr. **Washbourn** said the bacillus was present not only in the membrane, but also in the adjacent parts, and this would explain how it was that the membrane returned after removal.

Dr. **Newton Pitt**, in reply, referred to the energetic steps taken in New York, where an official doctor examined free of charge membrane from any patient, sending down two sterilised tubes to receive the specimen: within twelve or fifteen hours a message was sent to the medical men whether or not it was a case of diphtheria. In two out of three cases of membrane no bacillus was found. In Paris, if the bacillus were not found the children were sent back to their homes.

◆

HARVEIAN SOCIETY OF LONDON.

Meeting held Thursday, May 3rd.

The President, Mr. **George Eastes**, in the Chair.

HÆMORRHAGE INTO THE PLACENTA FOLLOWED BY DEATH OF FŒTUS AND MISCARRIAGE.

Dr. **Boxall** showed the product of a miscarriage at 4½ months from a patient, æt. 43, who was subject to so-called "habitual abortion." She had been pregnant six times. The first pregnancy terminated prematurely at 7½ months, the child being born alive, the others usually at four or five months. When the patient first came under observation two years ago there were evidences of long standing disease of the mucous membrane of the womb. It was decided in consultation to curette the uterus. Soon after the operation she became pregnant again. On that occasion she carried to the sixth month. On each occasion except the first there was evidence of premature death of the fœtus. Surmising disease in the afterbirth, Dr. Boxall expressed a desire to examine it. It was found that every cotyledon of the placenta contained an effusion of blood into its substance. This condition was probably the outcome of pre-existing disease of the lining membrane of the womb, which, though temporarily benefited, had not been cured by the operation. In this case there was no evidence or indication of syphilis either in husband or wife. While not denying the influence of syphilis in terminating the pregnancy prematurely in some cases, Dr. Boxall, speaking from experience of cases which had been under his own direct observation, was more disposed to regard syphilis, even when but recently acquired, as a cause of premature labour, of stillbirth, and of tainted and weakly offspring, it was not a frequent cause of abortion in the early months of pregnancy, though sometimes such cases did undoubtedly occur. In regard to the condition observed in this afterbirth, though he had carefully examined and noted the naked eye characters of some hundreds of placentæ, in a considerable proportion of which cases there was indisputable evidence of syphilis in both mother and child, he was not yet able to say among the various conditions observed what constituted a syphilitic placenta, at any rate as far as naked eye evidence was concerned extravasations, thrombosis, clots and cysts of various kinds occurred with equal frequency in the placenta of the healthy and of the syphilitic. To his mind it was clearly unwarrantable to found a diagnosis of syphilis solely on the occurrence of abortion or even of repeated abortion. In the first place endometritis with or without the presence of fibroid overgrowths was a common affection apart from syphilis, and in itself accounted for a large number of abortions, let alone extraneous influences, such as over-exertion, not to mention falls, blows, or even strong mental emotions. In the second place, as about 50 per cent. of child-bearing women sooner or later miscarried, if a diagnosis of syphilis, as some seemed to imagine, were warranted solely by the occurrence of abortion, it would, if followed out to a logical conclusion, lead to the unpleasant reflection that no less than half the mothers of our race were the subjects of syphilis.

CANCER OF THE COLON AND ITS TREATMENT.

Mr. **BLAND SUTOON** said that surgeons were in the habit of falling into methods of operating, perfecting that method which gave the best results. It was very necessary occasionally to formulate the facts upon which any such method was based. He said that there were clinically two kinds of colic cancer, firstly, one in which the mucous and submucous coats of the bowel became infiltrated with the malignant growth leading to a constriction of the gut, as if a tape had been tied round it, this was less malignant, and occurred later in life than the next variety; secondly, the "tuberous" form in which a definite tumour was found, and in which the growth infiltrated all the coats of the bowel, and then blocked up the lumen of the gut, this form occurred usually between the ages of 30 and 40. Both kinds were histologically the same, but this clinical distinction between the varieties was very important. Mr. Sutton then described the symptoms of the disease, and explained the "spurious diarrhœa." He said that the gut above the stricture became very dilated, and the fluid portions of its contents trickled through until a more solid piece of fæcal matter suddenly blocked up the orifice, then frequently a part of the growth sloughed away and a very copious evacuation took place. The temporary blocking of the orifice explained the apparent constipation, which so often alternated with the diarrhœa. The curious lethargic condition of the patient, with fœtid breath and deranged mental condition during this constipation was referred to, and shown to be due to the stored-up fæces. The causes of death in colic cancer were next discussed. These were three in number: 1. Death from poisoning from the contents of the bowel, 2. Death from perforation either above the stricture or in the cæcum leading to the escape of the contents of the bowel into the peritoneal cavity. 3. Death due to perforation into the inter-muscular planes of the abdominal walls—perhaps through the meso-colon leading to extensive suppuration and sloughing. The diagnosis of colic cancer—the disease never betrayed itself until obstruction occurred, hence the whole clinical aspect of the disease was conjectural, in some cases it might be possible to feel a tumour through the rectum, vagina, or abdominal walls. Mr. Sutton then described the method which he employed in the treatment. The anœsthesia should at first be not deep, then an exploratory incision in the middle line of the abdomen was made, and the cavity of the abdomen explored with the finger until the seat of disease was found. This could be done by following up the empty gut, beginning at the sigmoid flexure. In this way it could be ascertained where the colotomy should be done, *i.e.*, in which portion of the colon. The preliminary incision was then closed, and the operation of colotomy was done. He believed that the lumbar operation (after the preliminary operation referred to above) was the operation of the future. He deprecated so-called "chance" colotomy, that was colotomy done without being certain where the disease actually was situated, as it often happened that surgeons did first a left colotomy, and found the gut empty, then turned the patient and did a right colotomy, and might then even have to do a median operation in the end. Mr. Sutton then quoted cases which showed the importance of this preliminary exploration, and mentioned the following advantages of his method:—1. It prevented an unnecessary colotomy. 2. It eliminated the presence of a pelvic tumour which might be causing the obstruction. 3. It made certain the fact that one was dealing with a case of colic cancer.

The **PRESIDENT** attributed the peculiar mental condition of many of these patients to the absorption of toxic substances through the ulcerations found in the distended bowel above the cancerous disease. He had seen a large fæcal extra-peritoneal abscess opened during lumbar colotomy, which had been caused by perforation of the colon at a spot where it was not covered by peritoneum. An exploratory incision, such as that advocated by Mr. Sutton, would lead to avoidance of errors in respect of the proper site for operation. In cases of distended stomach and of vomiting, he recommended the emptying and washing out of the stomach by a long œsophageal tube before administration of an anæsthetic for abdominal exploration, and he considered it safer to use ether by inhalation as the anæsthetic, at any rate, in advanced cases, rather than employ hypodermic injections of cocaine for the production of local anæsthesia at the site of the surgeon's incision. He was in favour of dividing the operation into two parts, opening the bowel later on, if the patient could wait.

Dr. **ALEXANDER MORISON**, referring to the mental phenomena observed in cases of intestinal obstruction, said that he believed that in a certain number of these cases, the phenomena in question were exaggerated by the cumulative effects of belladonna given alone or in conjunction with opium. He thought belladonna generally out ran opium.

Dr. **BOXALL** had often had the opportunity of observing in lying-in women the peculiar fact, still awaiting a complete explanation, that fæcal accumulations as long as they are left undisturbed, are comparatively innocuous, but as soon as a successful attempt is made to dislodge scybala from the bowel, unpleasant symptoms often accompanied by fever, and not infrequently by urticarious skin eruptions, are apt to ensue.

Mr. **BEALE** thought that the symptoms following fæcal accumulations were due to absorption into the blood of albumoses produced during the life of micro-organisms. There was, in all probability, an extensive, though not deep, ulceration of the mucous membrane of the bowel, which was round the scybala, and thus the poisonous material easily entered the blood-stream.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF PATHOLOGY.

MEETING HELD FRIDAY, APRIL 17TH.

The President, Prof. J. **ALFRED SCOTT**, in the Chair.

EXHIBITS.

DR. **W. H. THOMPSON** exhibited a fresh fœtus with malformation of the posterior part of the head and of the neck.

Dr. **STORY** wished to know did he consider the specimen as an exaggerated instance of spina bifida, in which the non-closure existed in the occipital region?

Dr. **NIXON** suggested that a careful dissection should be made.

Dr. **THOMPSON** briefly replied.

Dr. **NORMAN** showed microscopic preparation of a sarcoma of the kidney.

Mr. **F. ALCOCK NIXON** read notes of a case of head injury illustrating some points in cerebral topography. The patient suffered from concussion and compression of the brain. There was inflammation of the membranes at the base, implicating the 7th, 8th, and 9th nerves. Blood clots occupied the auditory and speech centres. The difficulty of an accurate diagnosis arose from the co-existence of inflammation and pressure symptoms, the latter predominating, and to a great extent obliterating many of the symptoms which would have been present in a case of pure meningitis and cerebritis.

Dr. **STORY** asked were any external injuries visible. It would be extraordinary if with such extensive intracranial injury no external marks were to be seen.

Dr. **NIXON** replied that he had examined the scalp with care, and could not find any external sign of injury. On cutting into the scalp, *post-mortem*, he found a clot in the occipital region corresponding to the internal injury,

Dr. **R. H. WOODS** exhibited a specimen showing tertiary syphilis of the larynx. The patient from whom it was taken contracted venereal disease at the age of twenty, and a year later was tracheotomised in the Richmond Hospital for stenosis of the larynx, caused by gummatous infiltration of the false vocal cords. After some weeks' treatment and rest the swelling subsided, the tube was removed, and the patient discharged. In spite of the cautioning he received on his dismissal, he drank heavily, and exposed himself by sleeping out of doors, with the result that a few weeks later he was brought to hospital almost asphyxiated. Tracheotomy was again performed, and the tube left permanently in. Twelve months later he died from acute pneumonia. The larynx at its junction with the trachea was so stenosed as scarcely to admit the passage of a goose quill. There was no ulceration.

The Section then adjourned.

France.

[From our own Correspondent.]

Paris, May 20th.

Epididymitis.

Dr. Rollet gave, a few days ago, an interesting clinical lecture, at the hospital for specific diseases in Lyons, on the nature and treatment of blenorrhagic epididymitis which I consider well worth reporting :—

How does blenorrhagia produce epididymitis? Before answering the question, two theories must be rejected, that of sympathy of the reflexes, which was the opinion of Brown-Séquard and his school; that of retention of the sperm in the seminal ducts, as adopted by Després, but which was unable to stand the test of experimental facts, as the obliteration of the deferens canal in animals did not produce orchitis.

Another explanation which might be considered more plausible was that of metastasis. The idea was accepted for a long time, and in late years more or less abandoned; but to-day, thanks to modern research on toxic principles, the theory of metastasis has been more firmly established.

As to the anatomo-pathological interpretation of blenorrhagic epididymitis, the most natural consists in considering the complication as the result of the propagation of the virus by continuity of the mucous tissue, as witnessed in metro-salpingitis. Before now Postello compared the fimbriated extremity of the Fallopian tube to the epididyme, and in our own day Bernutz proved the great analogy which existed between blenorrhagia of the Fallopian tube and epididymitis. The lymphatics were considered by Sappey to be the tracts selected by the virus; but that idea did not find many partisans.

What is the specific agent which determines the complication of epididymitis in the cause of a gonorrhœa? Is it the gonoccoccus itself or the toxic principles which it secretes? If the recent researches of M. Hugomenq and Eraud, of Lyon, are correct, the affection would be caused by a microbe, different from that of blenorrhagia, but which can be found side by side with the gonoccoccus, and when present is a sure indication of threatened epididymitis; when absent, the blenorrhagia may be considered as a benign affection.

Consequently, and to prevent this painful complication, the urethral secretion should be cured as rapidly as possible.

Heisler found that the extension of the blenorrhagia to the posterior portion of the canal occurs during the first week in 20 per cent. of the cases—consequently, after that period the whole length of the urethra should be washed out with antiseptic solutions. Permanganate of potass has been tried with much success; but gallo-bromol, at 40 per 1,000, is particularly indicated in the most painful form of the malady.

If the epididymitis declares itself in spite of all treatment, the injections must not be suspended, as the virus might attack the second organ, and thus render the individual sterile. The orchitis itself can be treated internally and externally; internally by either salicylate of soda, a drachm and a half daily, as practised by Hendersore and Dr. Castel, or tincture of pulsatile anemone, 10 drops three times daily, as recommended by Dormand. The action of this agent is not as constant as that of the first-named. The external treatment is not so easy to determine on account of the numerous agents employed hitherto—tincture of iodine, chloroform, purphenic acid, collodion, mercurial ointments, &c. All these remedies have been more or less tried with very varied results. In the lecturer's mind refrigeration was about one of the best methods for relieving the pain, produced by either the application of ice to the inflamed part, or the spray of chloride of ethyle. However, this latter agent should be used with caution, as the skin of the scrotum is very sensitive. Reclus recommended the application of compresses of warm water. M. Rollet has been using for some time back with considerable satisfaction, guaiacal, which he applies by means of a brush over the surface daily; not more than one gramme or twenty drops is used each time. The pain produced by the agent is very slight and of short duration, while that appertaining to the malady disappears in about two hours and the fever falls also. The patient need not remain in bed if furnished with a good suspensory bandage. To resume, the best treatment in the lecturer's opinion of epididymitis is, salicylate of soda internally and guaiacol externally, and a suspensory bandage.

Germany.

[From our own Correspondent.]

Berlin, May 16th.

THE SURGICAL CONGRESS.

The afternoon sitting of the second day of the Congress was taken up with

Investigations into the Infection of Wounds,

The subject being introduced by Hr. Schimmelbusch, of Berlin. The experiments related showed that any virus entering the sytem through a recent wound found its way into the central organs of the system—lungs, liver, brain, and spleen—in an incredibly short space of time. In 90 per cent. of experiments with the most varied excitors of disease the infection was thus carried into the centre of the organism, and so far beyond the reach of any local antiseptics in from 5 to 10 minutes. It may be noted that the site of the experimental inoculation was the tails of mice and rabbits, and it was found that the best results were obtained when these were amputated as soon as possible after such inoculation. Burns and wounds from caustics, and such as were covered by a scab were not easily inoculated. Bacteria inoculated into the cornea of a living rabbit grew in a radiating manner; in the cornea of a dead one, on the other hand, the growth was more massed together.

Dr. Messner, of Munich, then reported on his experimental studies into the treatment of infected wounds. He infected wounds in rabbits with pus cocci and then washed them, a part in neutral saline solution, and others in a 3 per cent. solution of carbolic acid. The first group of animals all died in from 8 to 14 days; those of the second remained sound. The speaker claimed that his experiments pointed decidedly to the superiority of antiseptic over mere aseptic treatment, and that the latter had of late years unfortunately taken precedence of the other. It was believed by the aseptics that carbolic acid damaged the tissues.

Dr. Hermann, of Paris, said that during the past two years he had made a series of experiments bearing on this point. He made subcutaneous injection of a 3 per cent. solution of carbolic acid into rabbits, and an hour later inoculated them with 0·1 ccm. of a pure cultivation of staphylococcus pyog. alb. It was ascertained that although it required 1 ccm. of such a cultivation to kill an animal that had *not* received the carbolic acid, 0·1 or one-tenth the quantity killed when the animal had the carbolic injection previously. He believed, therefore, that carbolic acid should be used with caution, as it predisposed to suppuration. The speaker then repeated the experiment, using a sterilised ¾ per cent. saline solution in place of this carbolic acid. The results were the same as in the preceding experiment, the control animal in this case also showing no trace of suppuration in the wound. Carbolic acid itself, therefore, could not then be considered injurious, but it was the saturation of the tissues with fluid that predisposed to suppuration. The speaker, therefore, recommended the continued employment of carbolic acid, as it destroyed disease germs with certainty when it came into contact with them.

On the third day, the first business was a discussion on

Early Movement of Fractured Limbs in Ambulatory Dressings (Gehverbande).

Prof. v. Bardeleben introduced the subject. He said the treatment of fractures of the lower extremities had, as was known, changed very much during the last few years. Whilst it was a general principle formerly to keep a fractured limb completely immovable until repair had taken place, and in fractures of the lower extremity to keep patients fast for weeks, the opposite principle had obtained lately of allowing patients to walk about as soon as a suitable walking dressing (Gehverbande) was applied. The first step towards this swing of the pendulum was made by the French surgeon, Seutin, by the introduction of a pendant dressing by which some movement was permitted. About seven years ago, Feodor Krause had so arranged the plaster of Paris bandage in fractures of the leg that patients were able to walk, and he even actually allowed them to walk about soon after the bandage was applied. In some few individual cases, experiments had been made earlier. The speaker himself, thirty years ago, in springing from a carriage, fractured his ankle and dislocated his foot, and was able to go about the first day, and never laid up during the whole period of the recovery. But he had not the courage to repeat the experiment, and it was not till the summer of 1891 that experiments were made in the Charité under his direction by Staff-Surgeon Korsch, and since Easter, 1892, all fractures of the leg had been treated in this way.

During the last two years 116 fractures of the lower extremities had been successfully treated with walking dressings or splints. Eighty-nine of these were of the lower leg (12 compound fractures), 22 of the thigh (5 compound). The advantages of ambulant treatment were manifold. The patient did not require to stay six or eight weeks in bed, but was able to go about on his own broken limb a few days after the injury; he could perform the necessary functions without assistance, could devote himself to his business and his family, and decubitus and wasting of muscles were avoided. The whole of the organism felt the favourable influence of all this—the appetite, digestion, and sleep were those of the healthy individual. This ambulant treatment was of especial importance in the case of the aged and drinkers; the first class never had their frequent bronchial catarrhs made worse, nor any hypostatic pneumonia, and the second escaped their delirium tremens. The fractured bone healed more rapidly than when kept at rest. Of course, the dressing must be effective. In fracture of the thigh the chief point of support must be the tuber ischii, in the lower leg the condyles of the tibia. It must not be an excuse for inattention, as the greatest care was requisite. If there was much swelling it was better to wait three or four days, but when the dressings had been applied earlier no harm had resulted. If much swelling was present, however, the dressing generally had to be re-applied, as it became slack when it subsided. In compound fractures an aseptic condition of the wound would not, of course, be lost sight of. If these points were kept in view no particular danger need be expected in treating fractures in the way Korsch and his successor Allen explained the technique of the treatment. A gelatine plaster of Paris bandage was now used in the Charité, with iron bands when necessary to give the required firmness. A morphia injection was desirable before the application of the dressing, but no anæsthetic. The first attempts at walking should be made with a go-cart, on the principle of that used in teaching a child to walk. All the cases began to walk the day after the leg was thus put up, and they persevered until they could walk with crutch and stick, and later on with a stick only. A single putting up was generally sufficient. Amongst the patients exhibited was a labourer who had been run over 10 days before, and had sustained compound fracture of the femur and tibia. He got out of bed the first night under the idea that he was going to a dance. He was now able to get about quite "munter" with a crutch and stick.

◆

Austria.

[From our own Correspondent.]

Vienna, May 18th.

Carcinoma.

Professor Mosetig showed a patient to the Gesellschaft who suffered from carcinoma of the gall-bladder, which he was removing by means of pyoctanin pencils locally, and aniline internally. Under this treatment the patient seems to be greatly improved in his general condition.

Paralysis of the Prostate.

Prof. Hofmokl showed a young woman, æt. 27, on whom he had operated for incontinence of urine. A year ago she was suddenly attacked without any cause, shortly followed by pain in the bladder with paræsthesia of the extremities. The nerves from the cerebellum were normal, patellar reflex increased, while the functions of the bowel were unimpaired. If the bladder were filled mechanically with a catheter, the water dribbled away slowly, showing paralysis of the detrusor muscles. He resolved to perform Gersuny's operation of twisting the urethra which he did to the extent of 180° with the hope of producing a mechanical barrier this was crowned with success. The patient can now retain her urine for six or eight hours which she removes by a catheter.

Prof. Frisch remarked that in many of the cases reported by Gersuny the bladder leaked for several weeks after the operation and the urine could not be retained till the urethra was twisted 360°; to which Hofmokl replied that in his case paralysis of the detrusor muscle was present and did not require such resistance, which he considered was overcome by 180°.

Teratoma or Multilocular Cyst.

Prof. Hofmokl showed a child six months old with a large tumour over coccyx. When born, the swelling was no larger than a hen's egg, but since birth has grown larger than two fists. It is elastic, and has an internal feeling of another body which is movable, but attached to the coccygeal bones; compression has no effect in reducing it, neither does it produce convulsions. He believes this to be a teratoma, which Hirschsfeld designates subcutaneous parasites.

Weinlechner considered the swelling to be a multilocular cyst, the hard part within the large swelling appearing to him as an adventitious cyst. He thought the rational treatment in this case would be puncture and injections of iodine.

Paltauf thought that many of these cystic swellings should be considered teratoma. They frequently occur with gliomatous contents.

Tinnitus Auris.

Kaufmann showed a boy, æt. 14, in whom a noise in both ears was present subjectively and objectively, probably due to the action of the tensor veli with the movement of the uvula. Beyond this the child was normally healthy. Prof. Dittel said that he has often had the same sound produced without this suggestive movement of the uvula or absence of the osseous tube.

Prof. Gruber observed that the sound was only produced with each movement of the jaw, which frequently occurred in the case of clonic cramps in certain muscles.

Similar sounds could also be produced by the force of will and habit. He related several cases which had come under his notice where the sound was produced at his own suggestion. His treatment in the case of clonic cramp was a nutritious diet and general attention.

"Naturforscher-Versammlung."

Preparations are now in progress for this meeting here in September for which the large salon of the Musikverein has been secured. Three plenary meetings have been arranged, and the whole divided into forty sections, for which the Rector of the University has appealed to the Minister of Education and obtained the use of all the University rooms. Excursions to Kahlenberg, Greifenstein, Semmering, &c., have been planned. There will also be an exhibition of ancient relics in medicine over which Theodore Puschmann, Professor of Medical History in the University, will preside.

Billroth's Klinik.

Prof. Czerny, of Heidelberg, has been appointed to fill the Chair of Surgery vacated by Billroth.

◆

SOUTH AFRICAN MEDICAL NOTES.

A correspondent sends us the following items, which will be read with interest by those having friends in the Colony:—

Death of Dr. Cloete.

Widespread regret will be felt at the death of Dr. Dirk Cloete, which took place at Alphen, Wynberg, on Monday. Dr. Cloete had, during the past few years, resided at Pretoria, where he had become exceedingly popular among a wide circle of friends. Some time ago he was prostrated with a severe illness, but he sufficiently recovered to be able to travel to Wynberg, it being hoped that the change of air might do him much good, if not complete his restoration to health. Unfortunately, these hopes have not been realised, death taking place yesterday afternoon (19th April, 1894). It may be added that Dr. Cloete attended the course of study of Medicine at the Edinburgh University for 3-4 years, and graduated as M.B. and C.M. in August, 1884, and then returned to the Cape and joined Col. Warren's Expedition into Bechuanaland, and eventually settled down at Pretoria.

Treatment of Consumptives in South Africa.

Dr. G. S. Clarke contributes a sensible article to the *South African Medical Journal* on the "Treatment of Consumption in South Africa." He has some scathing but absolutely accurate remarks about snobbish little Bloemfontein, which, he says, claims a yearly number of victims. The point to which he alludes is the pecuniary inability of many patients to enjoy either good food, fresh air, or common hospitality. Arriving there with the little fund of capital (often subscribed by friends at home) nearly exhausted, the invalid's first anxiety is to get to work; but others have been before him, and invalid labour is at a discount. The sum which at home would have kept him in comfort secures him only the plainest food and a bed in a small room, often with two or three others. All the illusions and hopes formed at home are soon dead, and the patient quickly follows. Perhaps, on the other hand, work is obtained, and the hours which should be spent in the open air are spent in a close store, the breakdown soon comes, and the result is the same.

The Operating Theatres.

MIDDLESEX HOSPITAL.

Undescended Ovary.—The case operated on by Mr. **Bland Sutton** was that of a girl, æt. 19, only about 4 ft. 3 in. in height; a year before her left kidney had been explored and its cortex incised by him for suspected calculus, the prominent symptom being at that time profuse hæmaturia. No stone was then found, nor anything to account for the hæmaturia; but some months later she complained of pain in the left iliac fossa, and on examination, a peculiar elongated cylindrical body could easily be felt at the brim of the pelvis exactly in the position of the left ureter. Its position, hardness, and tenderness inclined him to believe that this body was a calculus impacted in the ureter, and it was with this view that the present operation was undertaken. The abdominal wall was incised exactly over the swelling, which turned out to be an ovary two inches and a quarter long, and in shape like a cucumber, resting upon, and in the same direction as, the ureter. The corresponding Fallopian tube lay beside the ovary; there were no evidences of inflammation either on the ovary or in its vicinity. Its pedicle was transfixed and secured with thin silk in the usual manner, and the organ removed. The right ovary and tube were normal in shape and position, and the uterus was also normal. The opportunity was also taken to examine the left kidney, which was found to be perfectly healthy, showing that the previous exploration had produced no deleterious effect on that organ. The wound was closed in the usual manner. Mr. Sutton said that the case was one of exceptional rarity. He had never before met with the condition save in malformed fœtuses, and even under these last, non-descent of the ovary was usually associated with malformation of the uterus. It was curious, he remarked, to find that this misplaced ovary retained its fœtal cucumber-like shape; he also observed that he had no explanation to offer of the extreme infrequency of non-descent of the ovary, whilst retention of the testis in the loin was a comparatively common condition; he thought also that it would be still more rare for such a condition to require surgical interference.

The ovary removed was subsequently microscopically examined and found to present normal ovarian follicles and ova.

Bilateral Nephorraphy.—The same surgeon operated upon a woman, æt. 30, who had been placed under his care for what was regarded as some obscure form of abdominal tumour. After watching her for some days in the ward it was found that she sometimes had a distinct tumour in the right iliac fossa, and sometimes in the left. It soon became clear that these suspected tumours were excessively mobile kidneys, and as the woman's urine was natural in quantity and quality there were no reasons for suspecting any disease of the kidneys. Her pelvic organs were natural, and she had never been pregnant. When the kidneys were much displaced they were the sources of much inconvenience and pain. The patient was, therefore, advised to have the kidneys sutured. The right kidney was exposed through an incision in the loin, and after cutting through the transversalis fascia the operator found that he had opened into a tunnel in the connective tissue which had been formed by the up and down excursions of the kidney. Some notion of the mobility of this kidney may be formed by the fact that its upper extremity was situated below the level of the incision; the lower end of the kidney could be felt in the neighbourhood of Poupart's ligament. A silk suture was passed through the muscles and made to transfix the posterior border of the kidney, the organ was then drawn upwards to the wound and fixed by means of the suture. The muscles were separately sutured with gut, and the skin and subcutaneous tissue united by waxed silk. The patient was then turned upon her right side, and the left kidney exposed: it was found to be displaced in the same manner as the right. An identical mode of treatment was adopted. Mr. Sutton said that he was not much in favour of nephorraphy save under exceptional conditions. In the present case the mobility of the kidneys exceeded anything he had before witnessed, and the inconvenience it caused was such as to prevent the woman from earning her living; therefore operative interference was a necessity. He observed that he felt some misgiving as to the propriety of dealing with both kidneys at the same operation, because the renal functions are sometimes temporarily suspended after these operations, but in this case he was sure, from repeated observations on the urine, that so far as their secretory powers were concerned these kidneys were in excellent condition.

It is interesting to record with regard to this case that a few days after the operation a hæmatoma formed in the capsule of the right kidney; this, as Mr. Sutton pointed out, was probably due to the fact that the patient was turned upon her right side whilst the left kidney was sutured. This condition necessitated a subsequent opening of the wound and removal of the clot. With this exception the patient is making a satisfactory convalescence.

It is reported that Professor von Esmarch has performed 20,000 important operations.

WEDNESDAY, MAY 23, 1894.

THE DIPHTHERIA QUESTION.

The interesting discussion which recently took place at the Hunterian Society, if it has not added to our knowledge of the important subject of the etiology and causation of diphtheria, serves, at any rate, the useful purpose of showing how we stand. It is thereby rendered painfully evident that our knowledge—clinical, pathological and bacteriological—of this disease presents huge gaps in every direction—gaps which years of patient investigation and observation will possibly be required to fill. We are, indeed, hardly certain so far that we have grasped the very nature of diphtheria; that is to say, what diphtheria is and what it is not. It is certain that other organisms than the typical bacillus of Loeffler are capable of determining membranous forms of inflammation of the throat. The presence of membranes in the throat is not, therefore, trustworthy evidence of the diphtheritic nature of the affection in particular cases. If the inflammatory process tends to involve the larynx that fact is stated to be strong presumptive proof of its diphtheritic nature, but that information comes too late in the course of a particular case to be of much service from a therapeutic point of view. Again, there is every reason to believe that cases of sore throat unaccompanied by membranous formation are not necessarily non-diphtheritic; in fact, it is a common experience for several members of the same family to have sore throats, one or more becoming typical diphtheritic, while the others never reach that stage. Why this should be so it doth not yet appear. This is a most important point, because the evidence goes to prove that diphtheria may be communicated by persons who themselves have never exhibited the clinical symptoms held, in the light of present knowledge, to characterise diphtheria. Unfortunately, bacteriology does not afford the assistance in diagnosis which one was entitled to anticipate. To begin with, bacteriological researches are delicate and tedious processes which cannot be expected to render much service in the hands of the busy practitioner. To afford either positive or negative evidence of practical value such investigations require to be carried out by experts. Then, again, bacteriological experts are not altogether certain as to their results, and they are not agreed among themselves on the interpretation to be placed on such results. The presence of the incriminated bacillus is not universally admitted to be absolutely indicative of diphtheria, and its absence is even less conclusive, for reasons which are too obvious to need mention. Dr. Sidney Martin's recent researches seem to prove as clearly as purely bacteriological researches can do, that the elaboration of the diphtheritic toxines takes place in the false membranes, yet clinically we know that removal of the membranes does not procure the relief, either immediate or remote, that one would expect under these circumstances. Indeed, if there be one thing as to which experts are agreed it is as to the inefficacy of any method of treatment. Hospital medical officers reluctantly confess that the mortality remains about the same whether an active local treatment is enforced or whether the sufferer is left severely alone. This may, perhaps, be partially explained in the case of hospital patients by the fact that most of them reach the hospital in a despairing condition. In any event, it would be a dangerous heresy to authorise the belief that local treatment is useless, because many a practitioner would gladly avail himself of any legitimate excuse for abstaining from applications which involve no small risk to the operator and a vast amount of discomfort to the victim. No one who has conscientiously carried out a local treatment on antiseptic lines will doubt for an instant that on general principles such measures must necessarily have for effect to minimise the toxic effects of the absorption of the foul products of post-diphtheritic ulceration. That, in spite of such precautions, the mortality, especially in young people, in whom the ordinary difficulties of local treatment are notably increased by their native unreasonableness, should still be high, can excite no surprise in view of the impossibility of obtaining access to all the diseased areas. It is a clinical fact that the less accessible the lesions the graver is the prognosis, as, for instance, in nasal diphtheria. The non-success of treatment, therefore, does not vitiate the conclusions founded on the results of bacteriological research. We cannot, however, make much headway with prophylaxis until we are in possession of a ready means of establishing the diagnosis in suspicious cases, for as matters at present stand these continue to spread the contagion without let or hindrance. Already in schools in epidemic times, one is fain to exclude every child presenting any throat lesions whatsoever, in order to make sure that infection shall not be introduced. The hygiene of schools, too, demands far more consideration than it has as yet received, for it is through and by these aggregations of highly inflammable material that the disease is propagated. Compulsory elementary education is largely responsible for the increasing extension of the disease, and some means must be found of combating its ravages, seeing that education cannot be foregone even for such a purpose. The relationship of diphtheria in domestic animals to the spread of the disease in man, is another of the highly obscure problems which investigators have to unravel. We are assured that the membranous throat affection which is at times rife in poultry, is an affection distinct from diphtheria as it presents itself in the human subject, but the last word has not yet been said on the polymorphism of bacilli, and it is probable that many surprises are reserved for us in this direction. The only sure thing after all is the lesson that all cases of sore throat must be regarded with suspicion, especially among the young, leaving it to experts to decide in the dim and distant future whether or not the membranous sore throat met with in association with scarlet fever and measles is or is not diphtheria, whether, and if so when, false membranes may be regarded as evidence of the diphtheritic nature of the disease, and what is the best method of treatment.

PROFESSIONAL SYMPATHY FOR MEDICAL MEN.

All professional men are more or less exposed to vexatious actions at law brought against them by persons who have everything to gain and nothing to lose by the transaction. But of all professional men, those who practise medicine are apt to suffer most, both pecuniarily and in social standing. The reason for this is self-evident. Apart from the costs of a trial, which make so heavy a demand upon the hard-earned income of a practitioner, the latter is haunted with the most gloomy and disturbing reflections of the manner in which the public will receive the result of the action. However strong and unassailable his position may be, these are some of the sources of mental worry which are apt to overwhelm him, pending the trial of the case. Then, until the trial can take place, all his practice, as it were, has to be conducted under a social cloud, the whole neighbourhood discussing the probability of his innocence or guilt. Some patients, it may be, take the opportunity of transferring themselves to other medical men, leading to the inference that reports so freely bruited about must be more or less truthful. With, therefore, practical evidences of his practice falling off, and being harassed with worries of all kinds, it is plain to understand how heavy must the lot of a medical practitioner be under circumstances like these. It should also never be lost sight of that, however much the judge and jury at the trial may pronounce in his favour, and vindicate his honour by showing their disbelief of the calumnious statements asserted against him, nothing will ever be able to repay him for the anxieties, troubles, and misery of which the trial was directly the cause. Nothing will enable him to forget that all the misery to which he was compelled to submit was brought upon him through no fault of his own. As a public duty, and for their own protection, medical men have no other course open to them than to defend vexatious actions promoted against them by patients or others with whom they have had professional relationships. It is, therefore, under painful circumstances of this nature that those of our *confrères* who have passed through the trying ordeal of successfully defending an action may reasonably expect to receive some marks of sympathy from the profession. Two cases of the kind have lately occurred which seem especially to call into existence a practical display of professional sympathy. We allude to the case of Dr. Griffiths, of Swansea, and that of Dr. Tait, of Highbury. It will be remembered that Dr. Griffiths was made the co-respondent in an action for divorce, which lasted for many days. A more cruel, heartless, and unfounded accusation, as the evidence showed, was never before brought against a medical man. Dr. Griffiths was triumphantly proved innocent of the charges of which he was accused, and, so far as the judge and jury were able to do so, his honour and reputation were thoroughly vindicated. With respect to Dr. Tait's case, the facts have been so recently reported that it is scarcely necessary for us to refer to them beyond pointing out that the action was one of malpraxis without a shadow of a foundation in fact. Dr. Tait had no difficulty in proving the worthlessness of the charge, and the care and attention which he had given to the patient. These two cases, as we have said, seem distinctly to call for some recognition at the hands of the profession with a view to the diminution of the heavy burden which Drs. Griffiths and Tait have lately had to bear. Practical sympathy by means of contributions to the funds which have been opened to defray the costs of the trials will be the best method of showing how the profession realises the cruelty of the position in which two of its members have been placed. We trust that a large sum in each case will be raised, and that medical practitioners throughout the kingdom will in this connection be mindful that *bis dat qui cito dat*. Dr. Griffiths has incurred at least a loss of £1,000, and, relatively, Dr. Tait's loss will be just as heavy. In both these trials the interests of the profession were upheld by Dr. Griffiths and Tait, and undeniably the result of each action, favourable as it was to the plaintiff, will be likely to prove a strong deterrent to other enterprising persons in the future who may feel disposed to put the law in motion against medical men.

◆

THE PROGRESS OF SURGERY.

In glancing over the "Operating Theatres" in the last two numbers of this journal one cannot help being struck by the enormous strides which have been made in operative surgery during the last thirty years. Here we have a case of abdominal obstruction undergoing three separate operations (all of which opened the peritoneum) making a rapid and complete recovery. What would have been the fate of such a patient a quarter of a century ago? The woman would in all probability have been treated with calomel and opium, together with leeches, fomentations, &c., and the abdomen only opened as an absolutely last resource when the patient was almost moribund; and, again, supposing Littré's operation to have been performed without giving relief, would the surgeon have had the courage to cut into the abdomen on the other side, and, not even then finding the obstruction, to carefully hunt through the small intestines? Probably not; and especially as the patient most likely would have been by that time *in extremis*. Nowadays the surgeon opens the abdomen with impunity, handles its contents with perfect safety, relieves the condition which causes the symptoms, and the patient gets perfectly well unless malignant disease happens to be present. Portions of bowel are resected, the stomach is opened, the gall bladder operated upon, splenectomies are not rare, colotomies, nephrectomies, and nephrotomies are very common, not to mention the long series of operations on the ovaries, Fallopian tubes, uterus, &c. In the 1869 edition of a well-known text-book on Surgery it is written that "gastrotomy is probably nearly as fatal as the disease for which it is undertaken, no case in which this operation has hitherto been performed for internal strangulation having recovered." How different is the record at the present time, and yet 1869 is only twenty-five years ago! Again, in the same work may be read, with regard to inguinal colotomy, that, "as the peritoneum must of necessity be wounded, an intense and frequently fatal peritonitis is the inevitable consequence." At the present time, peritonitis in its slightest form is quite of an exceptional occurrence after abdominal operations. It may well be asked whence comes this marvellous improvement in surgery, and especially in abdominal surgery? How is it that the peritoneum, that bugbear of former surgeons, which they hardly dared to look at, much less handle, can be treated by modern operators in so safe a manner? It would not be fair to say that the surgeons of the present time are so far superior to their predecessors as operators that the improvement is due to increased skill, for in the old days the surgeons obtained some marvellous results under what we now know to have been most unfavourable conditions. No! the great things which are done in surgery at the present time are mainly due to the absolute security which is procured by the use of cleanliness and antiseptics. The surgeon's, as well as the assistant's hands and arms, the part of the patient operated upon, the instruments, all are perfectly clean. Again, in abdominal cases, how thoroughly the belly is washed and flushed out, not necessarily with an antiseptic solution, many operators prefer plain though sterilised water. Perhaps anæsthetics and antiseptics have shorn surgery of some of its brilliancy, for in the old days it was a great point for the surgeon to operate quickly; but at the present time it may be truly said that surgery is not only very much more *conservative* with regard to the part operated upon, but also infinitely more *preservative* with regard to the patient's life; for whereas formerly operations were very often only undertaken as last resources, they now form part of the rational treatment of the case. This is well exemplified by the case referred to, in which but a few years ago the abdomen would only have been opened as a last resource, instead of this being done at once as a matter of course.

Notes on Current Topics.

Precautions against Cholera.

The continuance of the epidemic of acute diarrhœa in Lisbon is creating uneasiness among Continental authorities. Our contemporary, *El Siglio Medico*, is devoting special articles to the subject. The writer, Señor Decio Carlon, whose name is familiar to readers of this journal, states that at last the Government are showing a healthy activity in the matter. Sanitary inspectors, honorary and paid, are appointed to guard against the invasion of the disease at all the passes of the frontier of Portugal. What the effect of an outbreak of cholera in Spain would be, may be judged from the report of Dr. Shakespere to the U.S.A. Goverment on the sanitary state of Spanish towns. He writes: "Ordinary rules and customs that govern people in other countries are strangely absent in this land. In most villages, towns, and cities, the main streets, not alone those that are retired, but the more public as well, are made the receptacles for refuse at all times, and at Aranjuez, during the epidemic of cholera there in July, 1889, in houses where those ill of the disease had families to nurse them, and were allowed to remain, the cholera dejecta was thrown into the streets and into the back-yards! In Toledo, in two instances, the bedding and furniture of patients who had died of cholera were bought by second-hand dealers, put into their shops, and offered for sale! Most of the houses are very old; they are crowded together in dark, narrow, tortuous, dirty streets, with small, filthy back-yards, in which are sometimes the wells, though just as often they are sunken in the earth floors of the houses. In the small towns and villages there are no cesspools nor closets, as the streets are used for such purposes, and are made receptacles for every sort of refuse. In larger cities one sees in the vestibule of a handsome house a large circular stone sunk in the floor, and on inquiry, one finds that this stone is the cover of the common cesspool of the house." Madrid is, from a sanitary point of view, the best provided city in Spain. The Lozoya canal brings water from a distance of thirty-two miles, and the sewage falls into the Janiaro twelve miles from the capital. In promoting these works, and urging their accomplishment, the principal credit must be given to *El Siglo Medico*, which for the past forty and one years has been a fearless and able advocate of every reform in medicine, preventive and curative, in the Peninsula, nor has its labours been unrecognised. As a mark of special honour for the scientific work of the journal, its editor, Señor D. Matias Serrano was not long since raised to the peerage, as the Marquis de Guadalerzas. In this respect, the Spanish Government has given a good example to other European nations.

A Thermometer removed from a Male Bladder.

It is well known that foreign bodies of curious types may be sometimes found in the female bladder, for the female urethra, owing to its structure, does not much interfere with the wilful insertion of hair-pins and other such substances. The case, however, is very different when the male urethra is concerned. Experience teaches that it is not common for the surgeon to be called upon to remove a foreign body which has been intentionally introduced into the male bladder. However, a curious instance of the kind has just been recorded by Le Dentu. A young Breton, aged 26, was admitted under his care into the hospital with a history of having suffered for ten years from bladder symptoms. Micturition was frequent and painful, and the urine contained blood and a large quantity of pus. Exploration of the bladder with a sound revealed the presence of a calculus, the precise size and relations of which it was impossible to ascertain owing to the extreme irritability of the bladder. A supra-pubic cystotomy was performed, and when the bladder was opened a long and thin almost immovable calculus was found. An endeavour was made to extract the calculus entire, but this was unsuccessful; accordingly a pair of strong forceps was introduced into the bladder and the foreign substance was broken in half; the fragments were then easily removed. Subsequent examination showed, as had been suspected during the course of the operation, that the calculus had formed around some foreign body, and further investigation revealed that the latter was a thermometer, the length of which was ten centimetres. The patient made a good recovery. The interesting feature of the case, about which, however, the author says nothing, is the circumstances under which the thermometer came to be inserted into the bladder. It is curious, too, that for ten years the patient had never came under the care of a surgeon who had detected the presence of the foreign body.

The Gold Cure in Canada.

The College of Physicians and Surgeons of Quebec recently prosecuted a "Father Murphy" for having conducted an unlawful practice under the name of the "Gold Cure Institute." His defence was that the "Institute" was worked by a duly registered practitioner; but the evidence showed that this was only a "cover," and that the gold-curing injections were actually done by the Reverend Father and his subordinates. His reverence was accordingly fined 50 dols., or to go to prison for 60 days.

The Elections at the Royal College of Surgeons, Ireland.

The Examining Board was elected last Thursday, and we have little change in the Court to record. The Anatomico-Chirurgical Court remained unaltered, save that Mr. Myles succeeded Mr. Thomson, who retires in order to seek the Vice-Presidency of the College. There have been one or two unimportant changes in the Dental Court, and the Preliminary Court remains as before. The Examining Board is now constituted as follows:—Anatomy and Surgery: Messrs. Barton, Myles, W. Stoker, and Sir W. Stokes; Physiology, Histology, and Biology: Prof. Scott; Pathology: Mr. Patteson; Midwifery: Dr. S. Mason; Ophthalmology: Drs. Benson and Maxwell; Dentistry: Messrs. Barton, Burgess, Nevill, Reeves, Studeley, and Wall; State Medicine: Messrs. Pratt, Flinn, Patteson, and W. Malcolmson; Midwifery Diploma: Messrs. Goulding, Mason, and O'Donovan; General Education: Messrs. R. J. Montgomery and Robt. Morton. The election of a Court for the Conjoint Examinations with the Apothecaries Hall was deferred. The list of candidates for Council closed yesterday (Tuesday) at too late an hour to allow of our naming exactly the competitors. So far as we know, the whole of the outgoing Council seek re-election, except Mr. Myles, who, having been elected an Examiner, cannot do so. His abstention leaves a vacancy which would in ordinary course be filled by the return of Mr. Hamilton from the Presidential Chair to a Council seat, but there will be several other candidates. Dr. A. H. Jacob, whose name is sufficiently known in the College, will be one. Mr. Sherlock, of Westland Row, will seek a seat to represent not only the Fellows generally but the Dental speciality, which has at present no representative in the Council. Dr. Auchinleck, Professor of Forensic Medicine and Physician to Mercers' Hospital, will also be a candidate.

Chemists and Death Certificates.

An extraordinary and barefaced violation of the law by a chemist's assistant, with regard to death certificates, engaged the attention of the Coroner for Mid-Surrey, Mr. Braxton Hicks, on Friday last. This had its origin in connection with the death of Mrs. Lampert, the wife of an ironmonger residing at Merton. The husband stated that his wife had been attended by one, Haynes, whom he knew as assistant to Dr. Coffin ! of Holborn, and, on the day of her death, his daughter went up to Coffin's shop, and stated the serious condition the mother was then in, and induced Haynes to return with her to Merton. In the meantime, the mother died, and, after seeing the body, Haynes wrote out a death certificate, produced before the coroner. Mr. Lampert subsequently discovered that Haynes was not a duly qualified man, and that in consequence of the suddenness of his wife's death, an inquest would have to be held. The following particulars, as illustrating the laxity of administration and utter disregard of the law, came out in evidence:—Edward Haynes stated that he carried on the business called "Doctor Coffin's Medical Botanist Consulting Room," at 134 High Holborn. Dr. Coffin had been dead twenty-seven years, and a Mr. Brookes, a Cambridge University man, was now the responsible owner of the business. Witness was his manager. He became a qualified chemist in October, 1891, but he had managed the business some time before that. He had been attending Mrs. Lampert for four years, giving her medicine and advice, for which he was paid. He considered her to be suffering from weak lungs, and he diagnosed her as being consumptive. He arrived at that conclusion by sounding her. After her death he wrote out the certificate produced, signing it "Edward Haynes, A.P.S." He knew that the initials "A.P.S." was only a chemist's qualification, but he believed chemists all over the country gave certificates. The witness subsequently admitted having had no medical training at all. Dr. Thomas Brushfield, who made a post-mortem examination, ascribed the cause of death to heart and kidney disease, following hæmorrhage from the lungs. The Coroner, in summing up, said he disbelieved Mr. Haynes when he stated he thought he had a right to give the certificate. His opinion was that Haynes knew he was sailing near the wind and thought he would risk it. To give the jury some idea of Mr. Haynes' knowledge of diseases he would mention that he spelled "phthisis" with a "y." The jury returned a verdict in accordance with the medical testimony, and censured Mr. Haynes for giving a certificate, one of their number remarking that it was a lamentable thing that such documents should be issued in so loose a manner. The Coroner very properly said he would report the facts to the proper authorities with a view to further proceedings being taken, and we presume the last of this case has not been heard. We, therefore, defer further comment; we may, however, add, for the credit of our profession, that the so-called "Dr." Coffin was never a member of it.

The Mutilation of Landscapes.
